Supplementary Material Figure S1

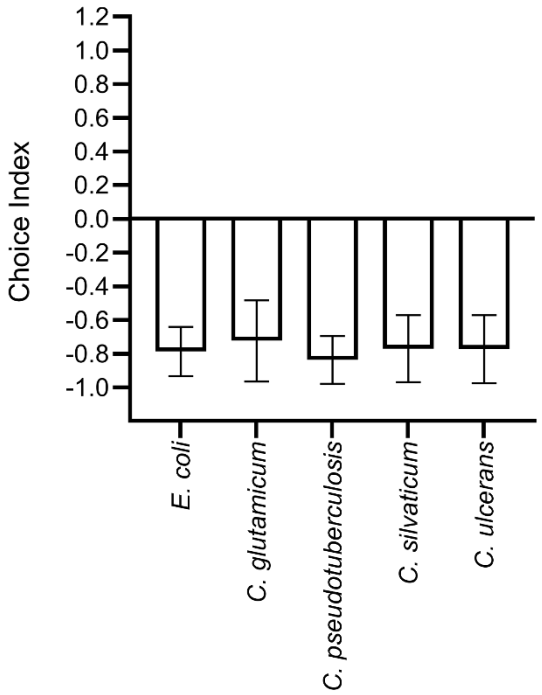

Figure S1. *C. elegans* chemotaxis. Worms were transferred to plates with two different bacterial species spotted on the surface. Worms located on bacterial lawns were counted after 24 h. and a choice index was calculated. Negative values indicate that all tested bacterial species and strains are preferred by the nematodes compared to *C. lactis* RW3-42. Experiments were performed in triplicate with approximately 20 worms per sample. Error bars represent standard deviations.
