

## Supplementary data

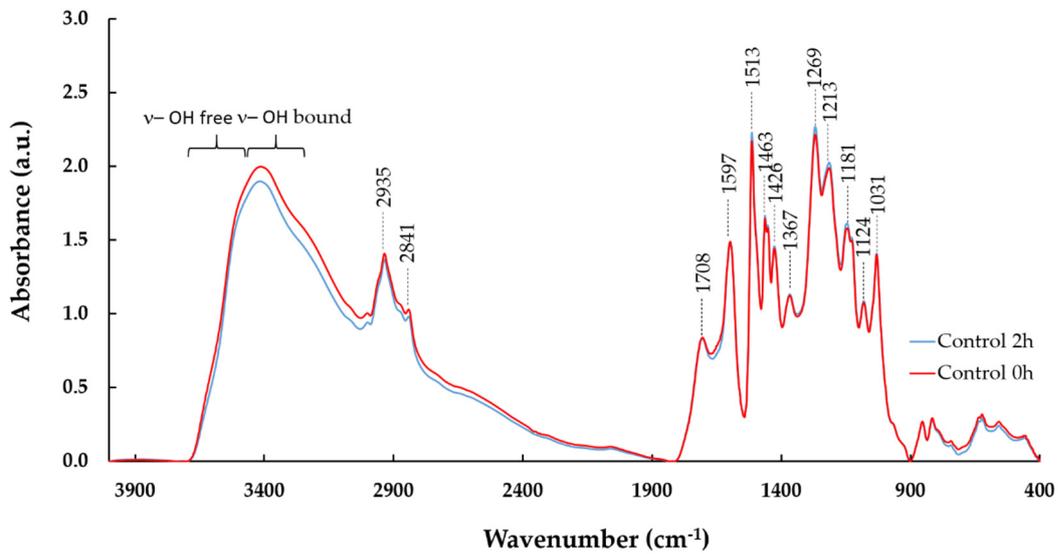

Figure S1: FTIR spectra of control kraft lignin incubated in buffer at pH 5.0 without HBT, for 0 and 2 hours.

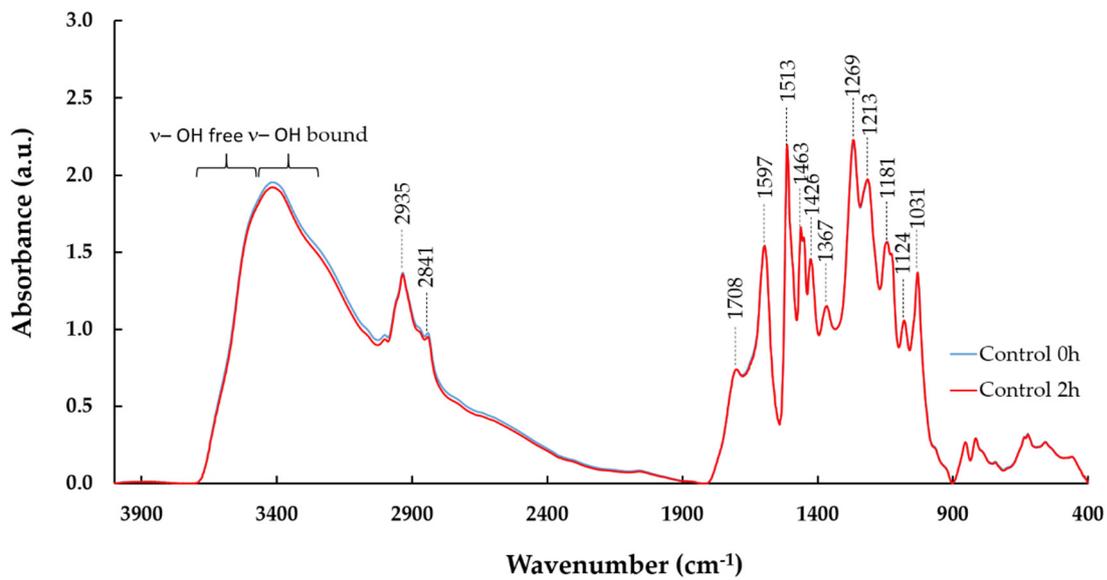

Figure S2: FTIR spectra of control kraft lignin incubated in buffer at pH 6.0 without HBT, for 0 and 2 hours.

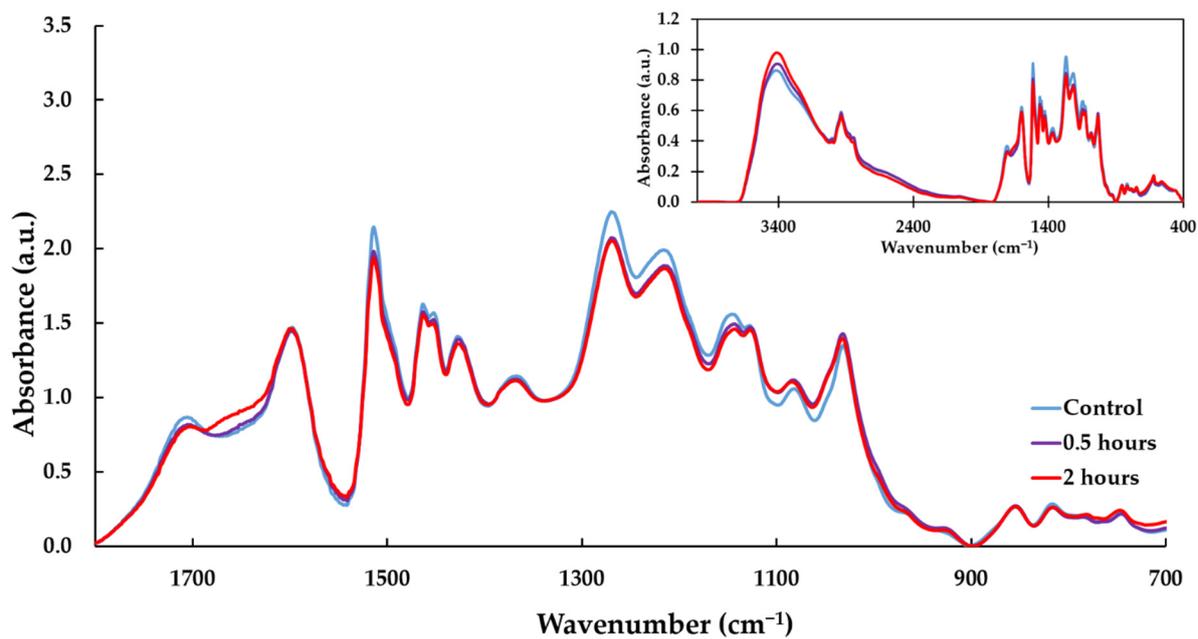

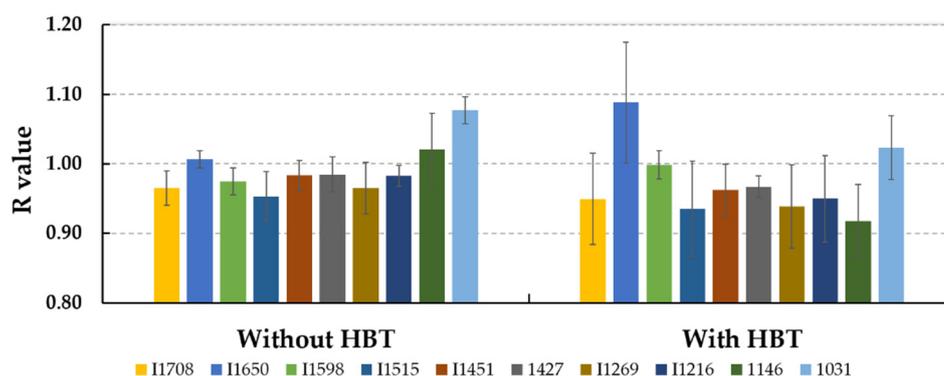

Figure S3: FTIR spectra of kraft lignin treated by *PciLac* with HBT (2%) for 0, 0.5 and 2 hours. Insert: full range. The vertical lines indicate the main bands of lignin detailed in Table 2.

Figure S4: (A) R values of 10 FTIR bands identified from loading profiles. R is the intensity ratio of each FTIR band between kraft lignin treated by *Pci*Lac (130 U/g for 2 hours) with and without HBT (2%) and the respective control. (B) Results of two-way ANOVA on 10 bands identified from loading profiles. Laccase activated lignins at pH 4.5 with 0, 13 and 130 U/g of *Pci*Lac, with and without HBT for 0, 0.5 and 2 hours. Differences vs. control were significant at F statistic > 1 and P<0.001 (red) or P<0.05 (pink).

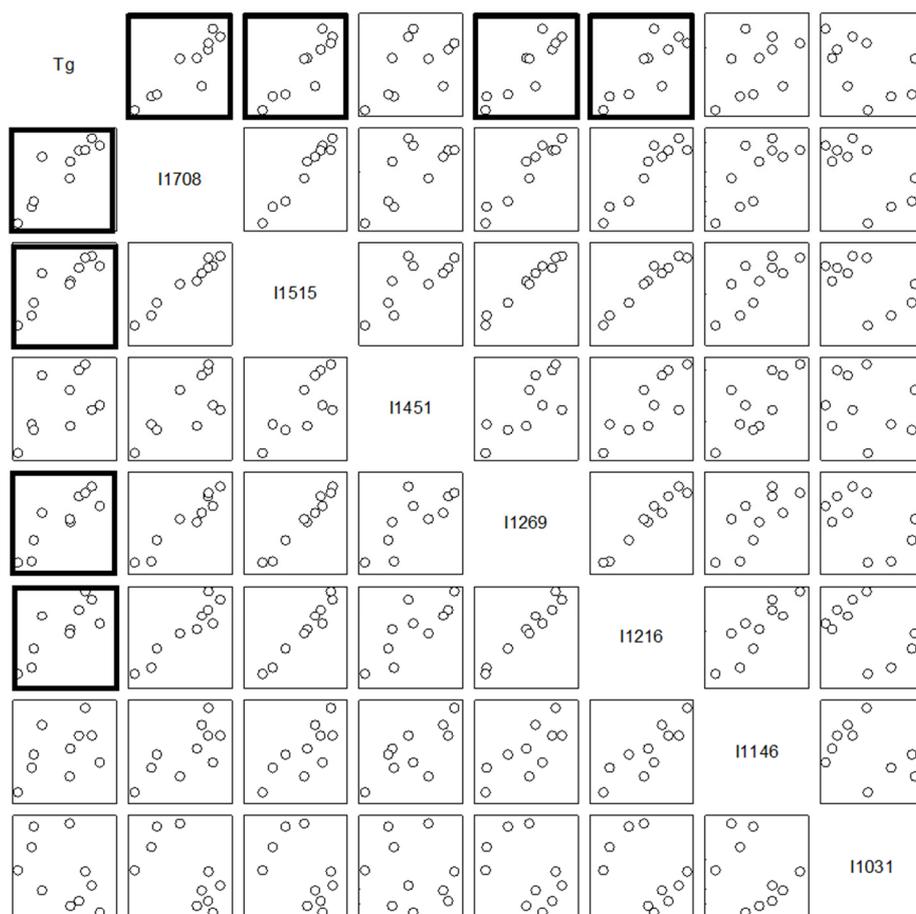

Figure S5: Scatter plot of Tg and the 7 significant FTIR bands (I1708, I1515, I1451, I1269, I1216, I1146, I1031) from figure 5c. Highlighted squares were the pair of variables with a positive correlation coefficient  $R > 0.87$  and P values below 0.001, except Tg & I1216 with  $R = 0.806$  and  $P = 0.005$ .
