General Remarks

Thin layer chromatography was done on silica gel coated plates (60F254, Merck), and Merck silica gel 60 (mesh 230–400, Merck) was used for column chromatography. HPLC was performed with a Waters chromatograph equipped with a 996 spectral diode array detector preparative SUPELCO, Ascentis® column (C18, 25 cm x 21.2 mm, 10 µm). Separation was run at room temperature (rt) using water as an eluent. NMR spectra were recorded at a 700 MHz (for ¹H) instrument and at 176 MHz for ¹³C. Chemical shifts (δ) are reported in ppm relative to TMS (an internal standard) for ¹H and ¹³C. The signal multiplicities are described as s (singlet), d (doublet), dd (doublet of doublets), t (triplet), q (quartet), m (multiplet), and bs (broad singlet). High-resolution mass spectrometry (HRMS) measurements were performed using Synapt G2Si mass spectrometer (Waters) equipped with an ESI source and quadrupole-Time-of-flight mass analyser or using a Finnigan MAT 95 spectrometer (FAB ionization).

Potentiometric measurements

The acidity constants of the nucleosides **1-3** (pKa) were determined by the pH-potentiometric titration of 2.0-ml samples. The concentration of the nucleoside in solution was 1×10^{-3} M. Measurements were carried out at 298 K and at a constant ionic strength of 0.1 M NaCl using a MOLSPIN pH meter (Molspin Ltd., Newcastle-upon-Tyne, UK) equipped with a digitally operated syringe (the Molspin DS1 0.250 ml) controlled by a computer. For the titrations, a carbonate-free NaOH solution of known concentration (0.1 M) was used and measurements were made using a Russel CMAWL/S7 semi-micro combined electrode, calibrated for hydrogen ion concentration using the method of Irving et al. The accepted fit for the titration curves was always less than 0.01 ml. The number of experimental points was 100–150 for each titration curve. The titration points included in the evaluation could be reproduced within 0.005 pH units in the whole pH range examined (pH from 2 to 12). The protonation constants of the nucleosides were evaluated by performing iterative non-linear least squares fit of the potentiometric equilibrium curves through mass balance equations using the computer program SUPERQUAD. The sigma value (the root mean squared weighted residual) obtained after the refinement of the stability constants was 1, which suggested that the data were fitted within experimental error. The equilibrium constants reported in this work were obtained from a fitting performed using three titration curves simultaneously.

4. Results of DFT calculations (Figures S27-S32, Tables S7-S8)

Structural analysis of m1Se2Ura and m1mm5Se2Ura

The theoretically determined lengths of all covalent bonds in the X2-C2-N3-C4-O4 bonding region of the tautomers of the m1Se2Ura and m1mm5Se2Ura models in water are shown in Fig. S28. Moreover, the C2-X bond lengths, where X=O, S, or Se, are compared in Table S7. Our calculations demonstrate that all C2-X bonds are quite sensitive to tautomerization and vary by approximately 0.1 Å upon conversion from the K form to the E2 form. Generally, the C2-X bond is the shortest in the K tautomer (which corresponds to the strongest double bond character) and the longest in the E2 tautomer (corresponding to the strongest single bond character). The C-Se bond in mm5Se2U is slightly longer in each tautomeric form than in unsubstituted Se2U (by 0.005-0.011 Å), but between the lengths for a pure C=Se bond (1.74 Å) and a pure C2-Se single bond (1.94 Å).^d

Electrostatic potential map

An electrostatic potential energy map illustrating the charge distributions in the most abundant mnm5Se2U base was analysed by quantum chemical calculations carried out for three of the most stable tautomeric forms of the m1mnm5Se2Ura model protonated at the amino alkyl residue. As shown in Fig. 5, the 2,4-diketo tautomer (K) contains electron-rich regions in the vicinity of both Se2 and O4 atoms, while N3 is shielded by the hydrogen atom. In the E4 tautomer, the electron-rich region is noted at the Se2···N3 location. In the zwitterionic tautomeric structure, the electron-deficient region is located in the vicinity of the ammonium cation at the side chain, while the electron-rich region is dispersed over the Se2···N3···O4 edge. The electrostatic potential maps obtained for the three tautomeric forms of the 2-selenouracil model are consistent with those of the corresponding 2-oxo- and 2-thio-uracils.^e
