Section S1. Plant_SNP_TATA_Z-tester as a Web service, automatic mode which was used to uniformly estimate how promoter-proximal SNPs can alter *Arabidopsis* gene expression in this work

In this work we used an automatic mode of our previously developed Web-service Plant_SNP_TATA_Z-tester [24] shown in Figures 1 and 5 (hereinafter, see the main text), the input data of which is two DNA sequences 90 bp long located just upstream the transcription start site (TSS, $s^{wt_0} = s^{min_0}$, where: $s^{\bullet_i} \in \{a, c, g, t\}$) of the proximal promoter analyzed of the *Arabidopsis thaliana* gene under study, such as: $S_{wt} = \{s^{wt_90} \dots s^{wt_{-1}}\}$ and $S_m = \{s^{min_90} \dots s^{min_{-1}}\}$ corresponding to ancestral (wt) or minor (min) allele, respectively, of a given SNP examined.

The result (i.e., output data) of this analysis is two quantitative sequence-based estimates *in silico* for two “ $-\ln[K_{D, AtTBP}(S_{\bullet})]$ ”-values expressed on the natural-logarithm scale (ln-units), which evaluate the TBP-promoter affinity upon each DNA sequences (S_{\bullet}) independently from one another [24], such as:

$$-\ln[K_{D, AtTBP}(S_{\bullet})] = 7.0 - 0.6\ln(K_{D, HsTBP}(S_{\bullet})). \quad (S1)$$

where 7.0 and 0.6 are linear regression coefficients, which were optimized by us in our previous article [24] using unique data from experimental measurements of the effect of the same mutations in the same promoter on the transcriptional activity of this promoter under the same conditions *ex vivo* using TPB extracted from either *Arabidopsis thaliana* TBP (AtTBP) or human TBP (HsTBP) [32]; $K_{D, AtTBP}$ and $K_{D, HsTBP}$ are the equilibrium dissociation constant estimation expressed in moles per liter, M, of the TBP extracted from either human or *Arabidopsis thaliana* for the considered alleles (i.e., S_{\bullet} as S_{wt} or S_m) of the *Arabidopsis thaliana* promoter upon their known DNA sequences of 90 bp in length.

First of all, within Eq. S1, $-\ln(K_{D, HsTBP}(S_{\bullet}))$ is calculated using our three-step model [25] of the TBP-promoter binding (i.e., TBP slides along DNA [26] \leftrightarrow molecular co-recognition between TBP and TBP-site met [27] \leftrightarrow DNA-bend stabilizes TBP-promoter complex [28]) which is proven experimentally [29], as follows:

$$-\ln[K_{D, HsTBP}(S_{\bullet})] = 10.9 - 0.2 \{ \ln[K_{SLIDE, HsTBP}(S_{\bullet})K_{STOP, HsTBP}(S_{\bullet})K_{BEND, HsTBP}(S_{\bullet})] \}, \quad (S2)$$

where; 10.9 (ln-units) seems to numerically match nonspecific TBP–DNA affinity (10 μ M) as measured independently [33]; 0.2 is a stoichiometric coefficient of the three-step TBP–promoter binding, as determined elsewhere by means of the difference in the length of the TBP consensus site and the region of TBP sliding along DNA [25].

Besides, within Eq. S2, $-\ln[K_{STOP}(S_\bullet)]$ is an estimation of the equilibrium dissociation constant of the mutual recognition between TBP and the most probable TBP-site encountered at the second step among the three steps in question:

$$-\ln[K_{STOP; HsTBP}(S_\bullet)] = \text{MAX}_{-90 \leq i \leq 20; k \in \{-1; +1\}} \left\{ \sum_{i-1 \leq j \leq i+13} w\{i, s^{\bullet}_j\}_k \right\}, \quad (\text{S3})$$

where $w\{i, s^{\bullet}_j\}$ is Bucher's weight of nucleotide s^{\bullet}_j at the j th position of the TBP-site [6]; k is an indicator of either a direct (+1) or complementary (-1) strand of the double-stranded B-helical DNA of the promoter under study.; $\text{MAX}(\zeta)$ is the highest ζ -value observed.

Additionally, in Eq. S2, $-\ln[K_{SLIDE; HsTBP}(S_\bullet)]$ is an estimate of the equilibrium dissociation constant of an interaction between TBP and the promoter DNA during their sliding one over the other at the first step among the three within this bioinformatics model, as:

$$-\ln[K_{SLIDE; HsTBP}(S_\bullet)] = \text{MEAN}_{[\xi - 7; \xi + 19]; k \in \{-1; +1\}} (35.1\mu + 0.8[TA]), \quad (\text{S3})$$

where ξ is the position of the most probable TBP-site according to Bucher's criterion [6] (i.e., Eq. S3); the μ value of the minor-groove width of the B-helical DNA at this site's center was determined elsewhere [34]; [TA] is the concentration of dinucleotide TA; 0.8 and 35.1 are linear regression coefficients [35].

Finally, in Eq. S2, $-\ln[K_{BEND; HsTBP}(S_\bullet)]$ is an estimation of the equilibrium dissociation constant of intermediate short-lived complexes between TBP and each of two DNA strands of the TBP-site separately from one another during DNA melting leading to the bend that fixes the TBP–promoter complex [28] at the last step of their binding, as follows:

$$-\ln[K_{BEND; HsTBP}(S_\bullet)] = \text{MEAN}_{[\xi - 7; \xi + 19]; k \in \{-1; +1\}} (0.9[TA, AA, TG, AG] + 2.5[TA, TC, TG] + 14.4), \quad (\text{S4})$$

where 0.9, 2.5, and 14.4 are linear regression coefficients [35].

After that, examining all the possible mutations, $s^{\bullet}_j \rightarrow \varphi$, at each j th position among 26 positions of the most probable TBP-site according to Eq. S3, our automatic mode of Web-service Plant_SNP_TATA_Z-tester [24] estimated standard error of the mean SEM_\bullet of the $-\ln[K_{D; AtTBP}(S_\bullet)]$ values calculated using Eq. S1, as:

$$\text{SEM}_\bullet = \left\{ \left(\sum_{\xi-7 \leq j \leq \xi+19} \sum_{\{a, c, g, t\}} \ln[K_{D; AtTBP}(S^{\bullet}_{\xi-7} \dots S_j \varphi S_{j+1} \dots S^{\bullet}_{\xi+19}) / K_{D; AtTBP}(S^{\bullet}_{\xi-7} \dots S_j S_{j+1} \dots S^{\bullet}_{\xi+19})]^2 \right) / ((3^*26)(3^*26 - 1)) \right\}^{1/2}. \quad (\text{S6})$$

Using both sequences S_{wt} and S_{min} and Eqs. S1 – S5, this toolbox found two paired value sets $\{-\ln[K_{D; AtTBP}(S_{wt})] \pm \text{SEM}_{wt}\}$ and $\{-\ln[K_{D; AtTBP}(S_{min})] \pm \text{SEM}_{min}\}$, respectively, which are necessary for Fisher's Z-score [36], for instance:

$$Z = \text{abs}[\ln[K_{D; AtTBP}(S_{wt}) / K_{D; AtTBP}(S_m))] / [\text{SEM}_{wt}^2 + \text{SEM}_m^2]^{1/2..} \quad (\text{S7})$$

Eventually, with the help of the R software [36], using this Z-value, our Web-service Plant_SNP_TATA_Z-tester [24] found a p value of the probability of the tested hypothesis " $H_0: K_{D; AtTBP}(S_{wt}) = K_{D; AtTBP}(S_{min})$ " so that if it is statistical significant ($p > 0.95$), it made the decision:

IF	{INEQUALITY "K_{D; AtTBP}(S_{min}) < K_{D; AtTBP}(S_{wt})"} is statistically significant },
THEN	{DECISION is "the minor allele of the gene considered is overexpressed relative to the ancestral one"};
ELSE	[IF {INEQUALITY "K_{D; AtTBP}(S_m) > K_{D; AtTBP}(S_{wt})"} is statistically significant},
	THEN {DECISION is "the minor allele of this gene is underexpressed relative to the ancestral one"},]
OTHERWISE	{DECISION is "the expression change of this gene is insignificant"}.

Dialogue mode of our Web service Plant_SNP_TATA_Z-tester [24] presents this decision (Eq. S8) in the "Decision" line of the "Result" textbox, while all the intermediate results are in the other lines of this textbox, as readers can see in Figure 5.

Table S1. Candidate SNP markers within the 90-bp proximal promoters of the *Arabidopsis thaliana* genes taken as an example of filling out the AtSNP_TATAdb database, created for the first time in this work.

#	<i>A. thaliana</i> gene (Entrez ID [37]; TAIR ID [38])	Candidate SNP marker			K _D , nM, MEAN ± SEM, <i>in silico</i>					Hand-curated annotation using the PubMed database [39]
