Figure S1. Co-treatment with 11-dehydroisunulariolide improved locomotor recovery in rats with SCI. The rats were treated with 11-dehydroisunulariolide immediately after SCI and on the following 6 days (once daily; total, 7 times; n = 2). Their behavior showed that the co-treatment process enhanced the recovery after SCI (A). However, the AUC of the co-treatment group was similar to that of the 1-μg group (180 and 193, respectively) * p < 0.05 compared with the vehicle group.
