Abstract: The occurrence of Harmful Algal Blooms (HABs) and bacteria can be one of the great threats to public health due to their ability to produce marine toxins (MTs). The most reported MTs include paralytic shellfish toxins (PSTs), amnesic shellfish toxins (ASTs), diarrheic shellfish toxins (DSTs), cyclic imines (CIs), ciguatoxins (CTXs), azaspiracids (AZTs), palytoxin (PITXs), tetrodotoxins (TTXs) and their analogs, some of them leading to fatal outcomes. MTs have been reported in several marine organisms causing human poisoning incidents since these organisms constitute the food basis of coastal human populations. In African countries of the Indian Ocean and the Red Sea, to date, only South Africa has a specific monitoring program for MTs and some other countries count only with respect to centers of seafood poisoning control. Therefore, the aim of this review is to evaluate the occurrence of MTs and associated poisoning episodes as a contribution to public health and monitoring programs as an MT risk assessment tool for this geographic region.

Keywords: Indian Ocean; marine toxins; harmful algal bloom

Key Contribution: The scarcity of MT data along African countries of the Indian Ocean and the Red Sea suggests the need for further studies and the creation of specific monitoring programs of MTs, particularly for dinoflagellates and diatoms since these constitute the phytoplankton that produces fatal MTs.

1. Introduction

The occurrence of Harmful Algal Blooms (HABs) in marine ecosystems can be one of the great threats to public health due to their capacity to produce marine toxins (MTs) as secondary metabolites [1–14]. MTs can be accumulated by distinct marine organisms such as fish, mollusks and crustaceans [15–24] which are the basic diet of coastal human populations. Suspected or confirmed episodes of human poisoning caused by MTs have been reported worldwide in the last century [20,21,25–48]. The occurrence of episodes of human poisoning occurs via ingestion of contaminated marine food due to the lack of monitoring programs in some countries or violations of national health authorities' regulations imposing the closure of harvesting areas and

seafood commercialization [18,20,26,35,39,45,47,49]. Despite the ideal environmental conditions for the formation of blooms in this geographical area, there are insufficient data related to their occurrence and toxin production [50]. This review analyses the occurrence of MTs and their producers along the African Indian and the Red Sea coasts (from Egypt to South Africa) and associated human poisoning episodes. The existence of monitoring programs of MTs will be also highlighted and finally, some suggestions for the control and prevention of marine toxins in this area will be presented.

2. Marine Toxins and Their Producers

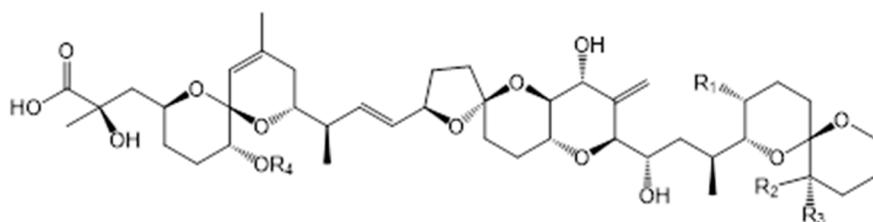

Chemically, toxins can be grouped according to their polarity, lipophilic and hydrophilic. Concerning MT monitoring, analysis and quantification methods in seafood are described in Table 1, including bioassays, immunoassays, and analytical chemistry methods. The bioassay methods (Mouse Bioassay (MBA), Rat Bioassay (RBA)) are no longer in use due to ethical reasons according to Directive 86/609/EEC [51] and procedural variation [52] (e.g., use of different extraction solvents and consequently shortcomings). Chemical methods, mainly liquid chromatography coupled to mass spectrometry, are considered as the most promising since they are fully validated and standardized to replace bioassays in many organizations worldwide. Further information related to each toxin group such as syndromes, producers, common vectors, symptoms, detections methods in seafood, limit of detection (LOD) and quantification (LOQ) and permitted limit used in some parts of the world is also described in Table 1.

2.1. Lipophilic Toxins

Lipophilic toxins are lipid soluble toxins and this group comprises okadaic acid (OA), ciguatoxins (CTX), cyclic imines (CIs) [spirolides (SPXs), gymnodimines (GYMs), pinnatoxins (PnTXs) and pteriatoxins (PtTXs)], brevetoxins (PbTx), pectenotoxins (PTXs), yessotoxins (YTXs) and azaspiracids [AZAs], Table 1.

2.1.1. Okadaic Acid and Analogs

Okadaic acid (OA) and their analogs, dinophysistoxins-1, -2 and -3 (DTXs) (Figure 1), are polyethers produced by dinoflagellates: *Prorocentrum* spp. [8], *Dinophysis* spp. [2,6,9,10,15,53,54] and *Phalacroma rotundatum* [55] (Table 1). These polyethers are frost-resistant and heat-stable and consequently, their toxicity is not affected by the cooking procedures in water (they are stable at <150 °C) [56]. The OA group is responsible for the diarrheic shellfish poisoning syndrome (DSP), with OA being the main representative of DSP toxins. Okadaic acid (OA) and its analogs act as inhibitors of the serine/threonine phosphoprotein phosphatases 1,2,2B,4,5 types [57,58].

Analog	R ₁	R ₂	R ₃	R ₄
OA	CH ₃	H	H	H
DTX1	CH ₃	CH ₃	H	H
DTX2	H	H	CH ₃	H
DTX3	H/CH ₃	H/CH ₃	H/CH ₃	Acyl

Figure 1. Chemical structure of OA and main derivatives [DTX1, DTX2, and DTX3].

2.1.2. Ciguatoxins

Ciguatoxins (CTXs) (Figure 2A) are a group of toxins produced by tropical and subtropical dinoflagellates species: *Gambierdiscus toxicus* and *Fukuyoa* spp. [59,60] (Table 1) mainly found in the Pacific, Caribbean and the Indian Ocean regions [P-CTX, C-CTX and I-CTX, respectively]. CTXs are lipid-soluble polyethers with 13–14 rings fused by ether linkages into a rigid ladder-like structure [60]. To date, the structures of 20 P-CTXs, 10 C-CTXs and 4 I-CTXs analogs have been fully identified and the most reported include P-CTX-1, P-CTX-2, P-CTX-3, P-CTX-3C [61–67], gambiertoxin [GbTXs, namely, P-CTX-4A and P-CTX-4B] [68], C-CTX-1, C-CTX-2 [67,69], I-CTX-1, I-CTX-2, I-CTX-3 and I-CTX-4 [70,71] mostly in predatory fish and gastropods [20,21,23,66,69,72–74]. The major analog of each group of CTXs is P-CTX-1, C-CTX-1, C-CTX-2, I-CTX-1, and I-CTX-2. The chemical structure of the last two (I-CTXs) have the same molecular weight and similar structures as C-CTX-1 [62,67,70,71]. CTXs are odorless and tasteless heat-stable molecules and are not affected when subjected to water cooking, freezing and acid or basic conditions, though they suffer structural alterations by oxidation [60]. CTXs and Maitotoxin (MTX) (Figure 2B) (produced by *Gambierdiscus* spp. [68]) were the first group of toxins reported to be responsible for ciguatera shellfish poisoning (CFP) [23]. The mechanism of action of CTX and analogs is to elevate calcium ion concentration and activate non-selective cation channels in cells causing neurologic effects in humans [75].

2.1.3. Cyclic Imines

Cyclic imines (CI) (Figure 3) are toxins produced by dinoflagellates: SPXs: *Alexandrium* spp. [1,76], GYMs: *Gymnodinium* spp. [77], PnTXs: *Vulcanodinium rugosum* [78] and PtTXs: biotransformation from PnTXs via metabolic and hydrolytic transformation in shellfish [1,5,77–79] (Table 1). CIs are a heterogenous group composed of spiroketides (SPXs), gymnodimines (GYMs), pinnatoxins (PnTXs) and pteriatoxins (PtTXs) and more than 24 structural analogs have been described to date [80].

Regarding chemical properties, these toxins are a group of macrocyclic compounds that have in common an imine functional group and spiro-linked ether moieties in their structure [80]. They are colorless amorphous solid macrocyclic compounds with imine and spiro-linked ether moieties [80], considerably soluble in organic solvents such as methanol, acetone, chloroform and ethyl acetate [5,80]. CIs are neurotoxins and act by inhibiting the nicotinic and muscarinic acetylcholine receptors (mAChR and nAChR, respectively) in the nervous system and at the neuromuscular junction [81]. CI bioactivity seems to depend on the imine functional group since the hydrolysis of spiroketides A–D produce spiroketal E and F with a keto-amine structure that is fully inactive [81]. To date, there are no regulations for CIs and no common symptoms can be recognized [82].

2.1.4. Brevetoxins

Brevetoxins (PbTx) (Figure 4) are cyclic polyethers produced by dinoflagellates: *Karenia* spp. [4,16,87] (Table 1). There are two known types of BTxs, named type A and type B (also called type 1(PbTx-1) and type 2 (PbTx-2), respectively). The difference between two types of PbTx consists in a few transfused rings that are ten for PbTx-1 and eleven for PbTx-2. The main analogs include PbTx-3, PbTx-6, PbTx-9, PbTx-B1, PbTx-B2, S-desoxy-PbTx-B2, PbTx-B3, PbTx-B4, and PbTx-B5 [44,88–94]. PbTx are lipid-soluble cyclic polyether consisting of 10 to 11 transfused rings [95], stable and resistant to heat and steam autoclaving [96]. PbTx cause neurotoxic shellfish poisoning (NSP) and act by binding with high affinity to receptor site 5 of the voltage-gated sodium channels (Nav) in cell membranes, and lactone is important for the toxin activity [97]. PbTx are regulated in USA [98], New Zealand, and Australia [99,100] (Table 1).

Toxin	R ₁	R ₂
PbTx-2	H	CH ₂ C[CH ₂]CHO

PbTx-1	2	H	CH ₂ C[CH ₂]CHO
PbTx-7	2	H	CH ₂ C[CH ₃]CH ₂ OH
PbTx-10	2	H	CH ₂ CH[CH ₃]CH ₂ OH

Figure 4. Chemical structures of the main group of PbTx (PbTx-A and PbTx-B). The capital letter A in first ring indicates type A and type B (also called type 1 and type 2, respectively [4]). These rings contain lactone group that is most important for the toxin activity.

2.1.5. Pectenotoxin Group

Pectenotoxins (PTXs) (Figure 5) are lipophilic polyethers produced by several dinoflagellate species [101] (Table 1). They contain spiroketal, bicyclic ketal, cyclic hemiketals, and oxolanes in their structure. To date, more than 15 PTX analogs have been documented and many are derived through biotransformation of PTX2 in marine organism metabolism such as bivalve mollusks [102]. The most reported analogs include PTX1, *epi*-PTX1, PTX2, PTX2 seco acid (PTX2 SA), 7-*epi*-PTX2 seco acid (7-*epi*-PTX2 SA), PTX3, PTX4, PTX6, *epi*-PTX6, PTX7, PTX11 (34S-hydroxy-PTX2) [6,101,103–105]. PTXs are heat-stable and unstable under alkaline conditions [103]. PTX and analogs alter actin-based structures [103,106] causing cell death and apoptosis [107]. PTXs co-occur with the OA—group and contribute to DSP in humans [108].

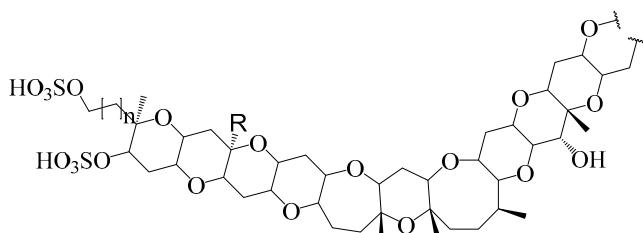

Toxin	Structure	R	Configuration at C7

2.1.6. Yessotoxins

Yessotoxins (YTXs) (Figure 6) are produced by dinoflagellates species: *Protoceratium reticulatum* [4,109], *Lingulodinium polyhedral* [4] and *Gonyaulax polyhedra* [4] (Table 1). They are a heat-stable polyether, with eleven transfused ether rings, an unsaturated side chain, and two sulfate esters [110]. To date, more than 90 YTX analogues have been isolated [102] and only YTX, 45-hydroxyYTX, carboxylic, 1a-homoYTX, 45,46,47-trinorYTX, ketoYTX, 40-*epi*-ketoYTX, 41a-homoYTX, 9Me-41a-homoYTX, 44,55-dihydroxyYTX, 45-hydroxy-1a-homoYTX, carboxy-1a-homoYTX [111] have been fully identified [111]. The mechanism of action of YTX and their analogs is not fully understood; however, they are involved in phosphodiesterase activation [112] and modulation of calcium migration at several levels [113], alteration of protein disposal [114], cell change

shape [115], apoptosis and cell death [116]. To date, there are no reports of human illness associated with YTXs [111].

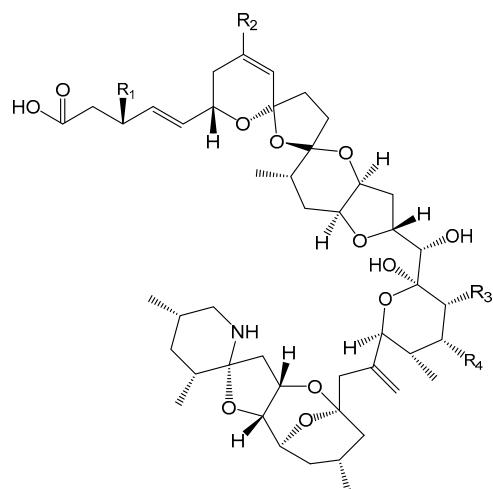

Toxin	R	n	Toxin	R	n		
YTX		H	1	40-epi-ketoYTX		H	1

KetoYTX		H	1	Carboxy-1a-homoYTX		H	2

Figure 6. Chemical structures of YTXs n corresponds to the number of methyl groups in the molecule.

2.1.7. Azaspiracids

Azaspiracids (AZAs) (Figure 7) are toxins produced by dinoflagellates: *Azadinium spinosum* [117] and *Protoperidinium crassipes* [118] (Table 1). They are colorless, odorless and amorphous solids of toxins containing a heterocyclic amine, a unique tri-spiro-assembly and an aliphatic carboxylic acid in their structures [117,119–124]. Around 21 compounds of AZAs are well known and documented [117,119–124] of which AZA, AZA2, AZA3, AZA4, and AZA5 are the most prevalent ones based on occurrence and toxicity in humans. AZAs are responsible for the AZP syndrome (Table 1) and their mechanism of action is the inhibition of hERG voltage-gated potassium channels [125].

Toxin	R ₁	R ₂	R ₃	R ₄
AZA	H	H	CH ₃	H
AZA2	H	CH ₃	CH ₃	H
AZA3	H	H	H	H
AZA4	OH	H	H	H
AZA5	H	H	H	OH

Figure 7. Chemical structure of AZAs.

2.2. Hydrophilic Toxins

Hydrophilic Toxins are polar soluble compounds and they include domoic acid (DA) and analogs, Paralytic Shellfish Toxins (PSTs), tetrodotoxins (TTXs) and palytoxins (PITXs).

2.2.1. Domoic Acid and Analogs

Domoic acid (DA) (Figure 8) and analogs are polar cyclic amino acid toxins of diatom origin *Pseudo-nitzschia* spp. [126] and red algae: *Chondria armata* [127] (Table 1). They present three carboxylic acid groups and the most reported DA analogs include *epi*-domoic acid (*epi*-DA), domoic acid C5'-diastereomer and isodomoic acids A, B, C, D, E, F, G and H [iso-DA A-H] [128,129]. DA is the representative molecule of the DA-group that is responsible for amnesic shellfish poisoning (ASP) syndrome [130]. The characteristic symptomatology of ASP is detailed in Table 1.

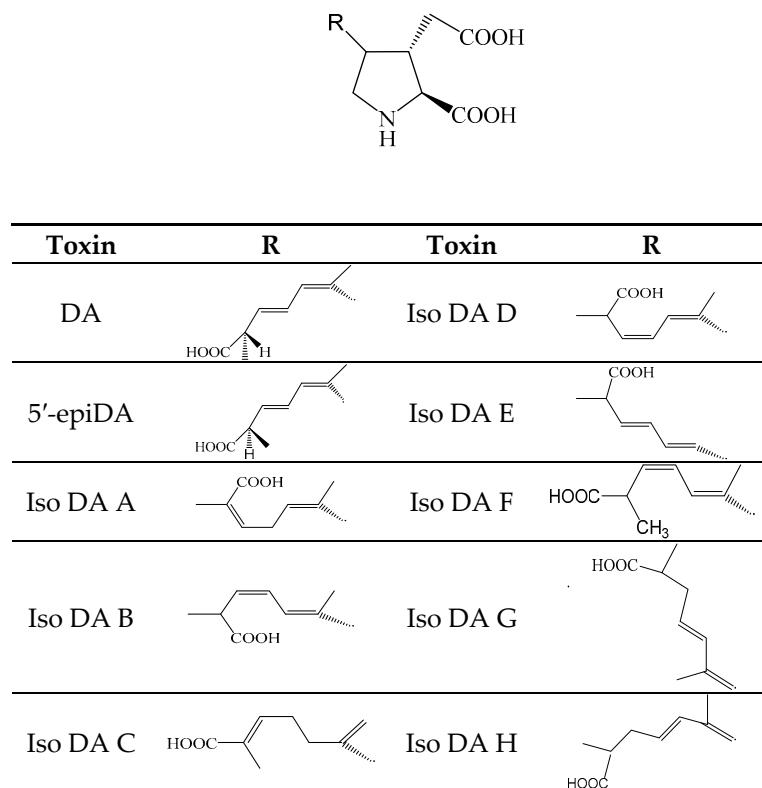

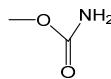

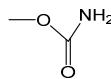

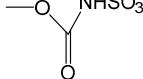

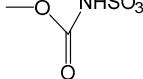

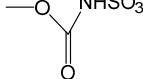

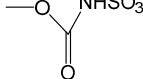

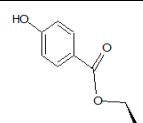

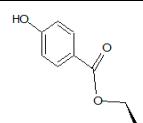

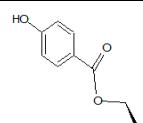

Figure 8. Chemical structure of DA and analogs.

2.2.2. Paralytic Shellfish Toxins.

Paralytic shellfish toxins (PSTs) (Figure 9) are water-soluble tetrahydropurine toxins produced mainly by dinoflagellates *Alexandrium* spp. [2,3,7], *Gymnodinium catenatum* [3], *Pyrodinium bahamense* [3] and by cyanobacteria *Trichodesmium erythraeum* [131] except M (Figure 9) toxins that are *Mytilus* spp. metabolism products [132]. This group is composed of several analogs and they are prone to various conversions depending on pH (Figure 9), being divided into several groups: carbamoyl (saxitoxin (STX), neosaxitoxin (NeoSTX) and gonyautoxins (GTX1-4)) decarbamoyl [dc-] (dcSTX, dcNeoSTX, dcGTX1-4), Nsulfo-carbamoyl [GTX5-6, C1-4], hydroxylated saxitoxins [M1-4] [133–135] and benzoyl toxins (GC1-3) [135]. Their heat stability is pH dependent (except for Nsulfo-carbamoyl components) [136]. STX and analogs act by binding to Nav and consequently blocking ion conductance in nerves and muscles fibers leading to paralysis [137]. Symptoms resulting from PSTs poisoning are described in Table 1.

Toxin	R ₁	R ₂	R ₃	R ₄

GC2	H	OSO ₃ ⁻	H	
GC3	H	H	H	

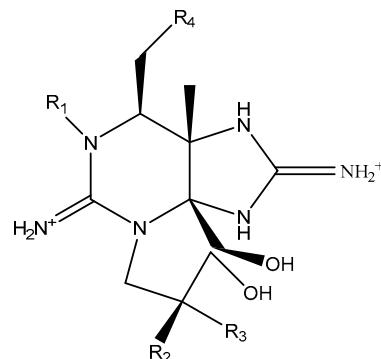

Figure 9. Chemical structures of STX group.

2.2.3. Tetrodotoxins

Tetrodotoxins (TTXs) (Figure 10) are toxins produced by bacteria in marine environments: *Serratia marcescens*, *Vibrio* spp. [83], *Aeromonas* sp. [138], *Microbacterium arabinogalactanolyticum* [139], *Pseudomonas* sp. [140], *Shewanella putrefaciens* [141], *Alteromonas* sp. [142], *Pseudoalteromonas* ssp. [143], and *Nocardiopsis dassonvillei* [144] (Table 1). They are colorless, crystalline-weak basic compounds with one positively charged guanidinium group and a pyrimidine ring [145,146]. TTX poisoning has been recognized since ancient Egyptian times [42]. To date, TTX is considered an extremely potent emergent toxin in the Atlantic Ocean [83] and acts by binding to Nav on the surface of nerve cell membranes blocking the cellular communication and causing death by cardio-respiratory paralysis [147]. Several poisoning incidents have reported in Asia [Japan is the most affected country] [148], the Mediterranean Sea and the Indian Ocean [35]. TTX is usually concentrated in the ovaries, liver, intestines, and skin of its principal vector [puffer fish] [42]. To date, the structures of 26 analogs of TTX have been fully elucidated but their relative toxicity and occurrence are not yet fully known [145,146] except for 12 compounds, namely, TTX, 11-oxoTTX, 11-deoxyTTX, 11-norTTX-6[R]-ol, 11-norTTX-6[S]-ol, 4-epiTTX, 4,9-anhydroTTX, 5,6,11-trideoxyTTX. [131], 4-CysTTX, 5-deoxyTTX, 5,11-dideoxyTTX, and 6,11-dideoxyTTX [149–152].

	5,6,11-trideoxyTTX	H	CH ₃	H	H	OH	

Figure 10. Chemical structure of TTX and their main analogues.

2.2.4. Palytoxin

Palytoxin (PTX) and its derivatives (Figure 11) are toxins produced by marine zoanthids *Palythoa* spp., dinoflagellates: *Ostreopsis ovata*, [153–155] and possibly by cyanobacteria: *Trichodesmium* sp. [156] (Table 1). These polyhydroxylated toxins have both lipophilic and hydrophilic properties [157] with a partial unsaturated aliphatic backbone containing cyclic ethers, 64 chiral centers, 40–42 hydroxyl and 2 amide groups [157]. Among PTX analogs, known are: isobaric PTX, ostreocin-D, ovatoxin [a to f], mazarenotoxins, ostreotoxin-1 and 2, homopalytoxin, bishomopalytoxin, neopalytoxin, deopalytoxin and 42-hydroxypalytoxin and their molecular weights range from 2659 to 2680 DA [158–160]. PTX and analogs act on Na^+ , K^+ -ATPase pumps molecules in the cell membrane [161] and the loss of intracellular contents into the blood plasma and consequent injury causing rhabdomyolysis, among other signs, are the most reported as signs of PTX poisoning [161].

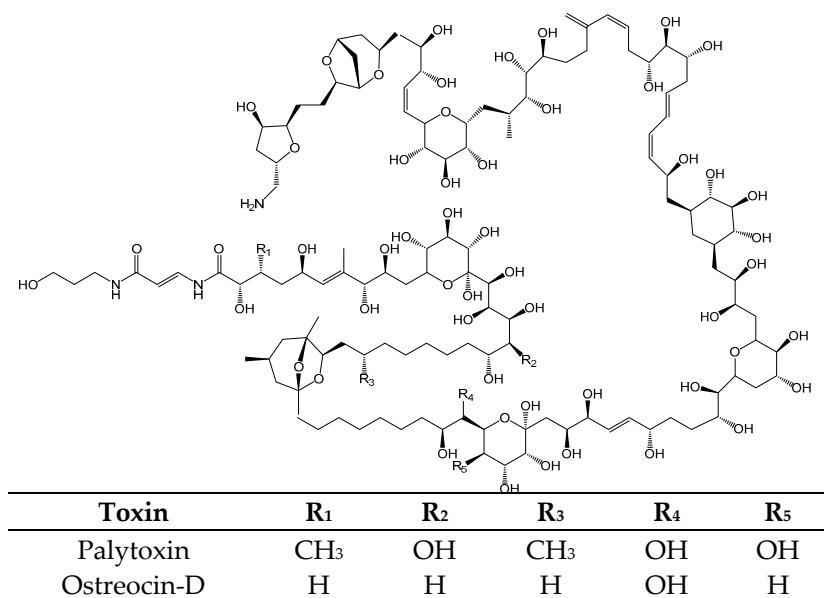

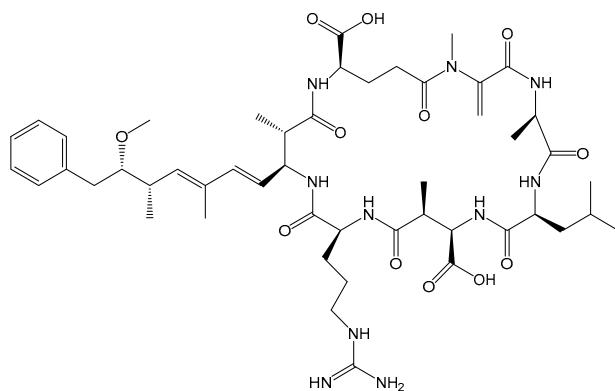

Figure 11. Chemical Structure of PTXs [PTX and Ostreocin-D].

2.3. Marine Cyanotoxins

Most marine toxins reported are produced mainly by microalgae (composed basically by dinoflagellates, diatoms, and marine bacteria), while cyanobacteria are reported as toxin producers in fresh, brackish waters and terrestrial habitats. Recently, cyanotoxins typical from freshwater have been identified in the marine environment [162]. Thus, this section will be focused on the description of the most reported marine cyanotoxins involved in seafood poisoning, their producers and mode of action (Table 1).

One of the most relevant groups of marine cyanotoxins is the microcystin group (MCs) [163] (Figure 12). MCs are produced by cyanobacteria of genus *Pseudoanabaena*, *Phormidium*, *Spirilia* [164], *Leptolyngbya*, *Oscillatoria*, *Geitlerinema* [165], *Trichodesmium* [166] and *Synechococcus* [167] and their occurrence have been reported in many parts of the world, namely: the central Atlantic coast of Portugal [168], Canary Islands Archipelago [166], Brazilian coast [169], Amvrakikos Gulf (Greece) [167] and Indian Ocean [170]. To date, MCs are regulated in freshwater habitats but should be extended to the marine environments since there are reports of these hepatotoxins in marine environments [162].

**Figure 12.** Chemical structure of MC.

Other reported marine cyanotoxins [in parenthesis is indicated their producers] (Figure 13) are aplysiatoxin (AT) [171] (Figure 13a), debromoaplysiatoxin (DAT) [171] (Figure 13) (algae *Gracilaria coronopifolia* [172] and cyanobacteria *Lyngbya majuscule* [171]), kalkitoxin (KTX) (cyanobacteria *Lyngbyamajuscule* [173]) (Figure 13b), lyngbyatoxins (LA, LB and LC) (cyanobacteria *Lyngbya majuscule* [174]) [Figure 13c], cylindrospermopsins (CYNs) (cyanobacteria *Cylindrospermopsis raciborskii* [175]) (Figure 13d), jamaicamides (JCDs) (Cyanobacteria *Lyngbya majuscule* [176]) (Figure 13e), anatoxins (ANTX) (cyanobacteria *Hydrocoleum lyngbyaceum* [177]) [178] (Figure 13f) and antillatoxins (ATX) (cyanobacteria *Lyngbya majuscule* [179]) (Figure 13g). The mechanism of action and detection methods are presented in Table 1.

Order	Structure	Toxin	R
(a)		AT	Br
		DAT	H
(b)			
(c)		7- <i>epi</i> CYN	OH, epimer at C7
		CYN]	OH
		do-CYN	H

Figure 13. Cont.

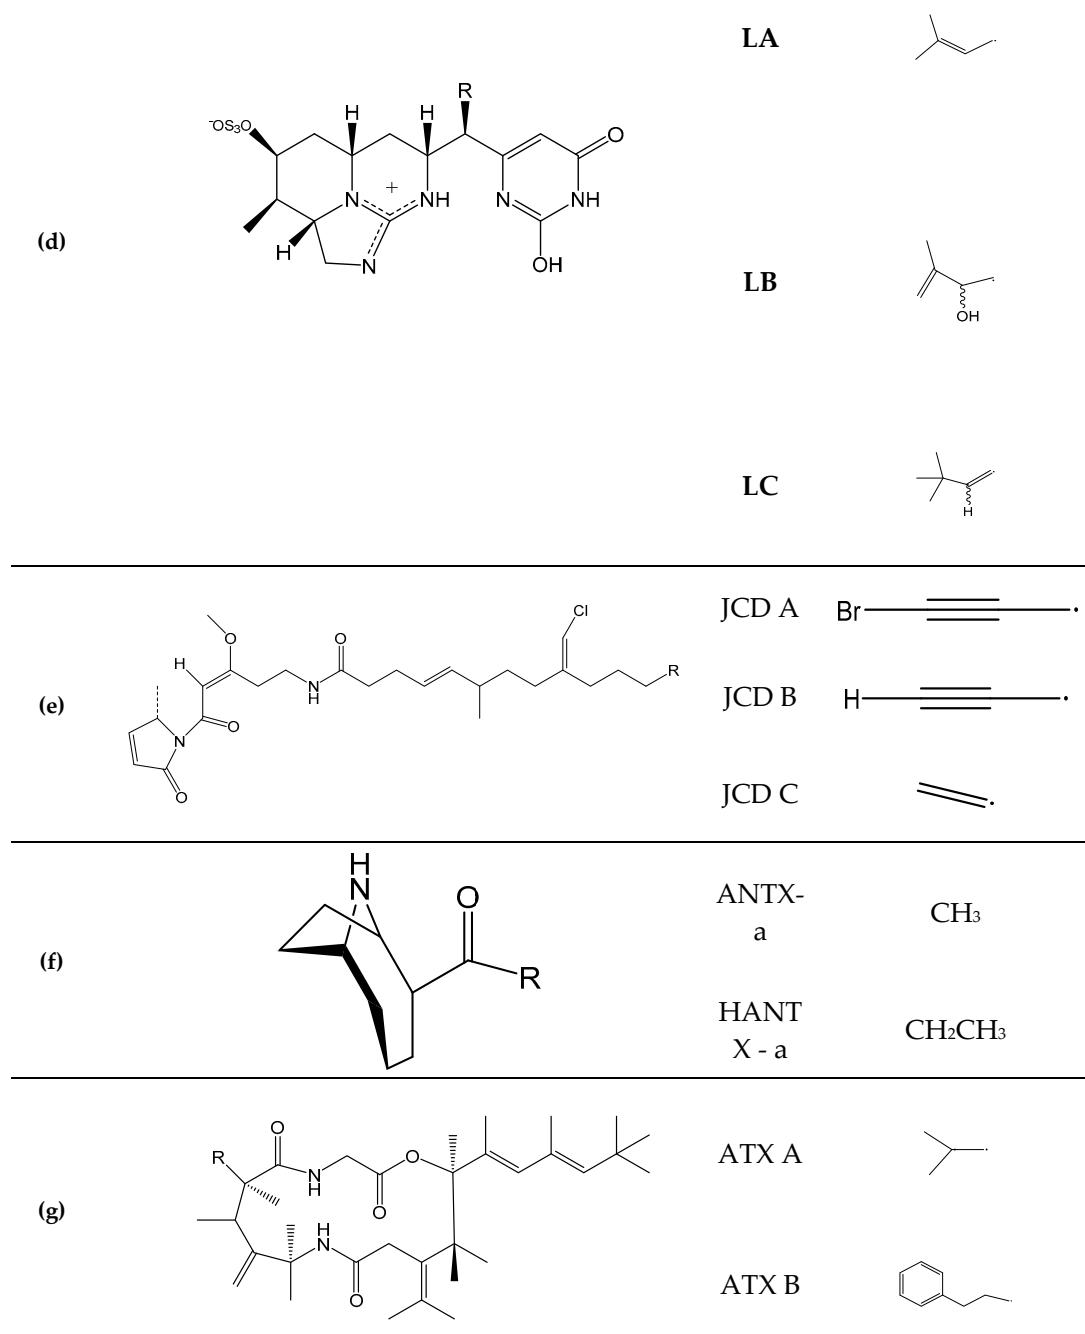

Figure 13. Chemical structures of Aplysiatoxin (AT) and Debromoaplysiatoxin (DAT) (a); kalkitoxins (KTX) (b); lyngbyatoxins A, B and C (LA, LB and LC) (c); cylindrospermopsins (CYN) (d); jamaicadimes (JCD) (e); anatoxin-a (ANTX) and homoanatoxin-a (HANTX) (f) and antillatoxins (ATX) (g).

Recent studies indicate Homoanatoxin-a (HANTX, a derivative of anatoxin-a) produced by the cyanobacteria *Hydrocoleum* sp. and *Trichodesmium* sp. which co-occur with *G. toxicus*, may be the causative toxin of CFP [43] (rather than CTXs). This evidence suggests further studies to clarify marine cyanotoxins responsible for CFP and their mechanism of action [178]. The reports of seafood poisoning involving marine cyanotoxins are very scarce and consequently, there is no specific symptomatology that can be related to marine cyanotoxin human poisoning.

Table 1. Marine toxins and their symptoms, producers, permitted limit, detection methods, limit of detection/limit of quantification [LOD/LOQ] and toxicity equivalency factors [TEF] according to the European Food Safety Authority [EFSA].

Toxin (Syndrome)	Symptoms	Detection			Permitted Limit	Toxin (TEF)	Producer

3. Incidence of Harmful Algal Blooms Marine Toxins and Consequent Poisoning Incidents along African Indian and the Red Sea Coasts

The main geographical focus of this review is the African Indian and the Red Sea coasts, including surrounding islands (Figure 14). The marine environment of this area is understudied due to a lack of monitoring infrastructure. There is a high rate of poverty in local communities, and the local population is vulnerable to natural disasters [including HABs, tropical storms]. The exponential increase in population accompanied by industrialization and climate change contributes to eutrophication in coastal areas [295,296]. This study area is characterized as subtropical to tropical climate with a water temperature above 20 °C [297]. Eutrophication and the transportation of cysts [through maritime traffic] are considered the main factors contributing to large phytoplankton blooms, including those comprised of HAB species and/or pathogenic bacteria [295,296]. Countries with monitoring programs of marine environments related to control of seafood poisoning are listed in Table 2. A few of these programs have noted the presence of MTs (Figure 14) and HAB species [dinoflagellates, cyanobacteria, diatoms], some of which [HAB species] were detected/confirmed by microscopic techniques and some confirmed by partial 16 S rRNA genes analysis [12,13,298–323].

Table 2. MT monitoring scenario of the African countries of the Indian Ocean and the Red Sea.

Country	Monitored MT	Permitted Limit, mgKg ⁻¹ Shellfish	Detection	Laboratories for Toxin Analysis	Reference

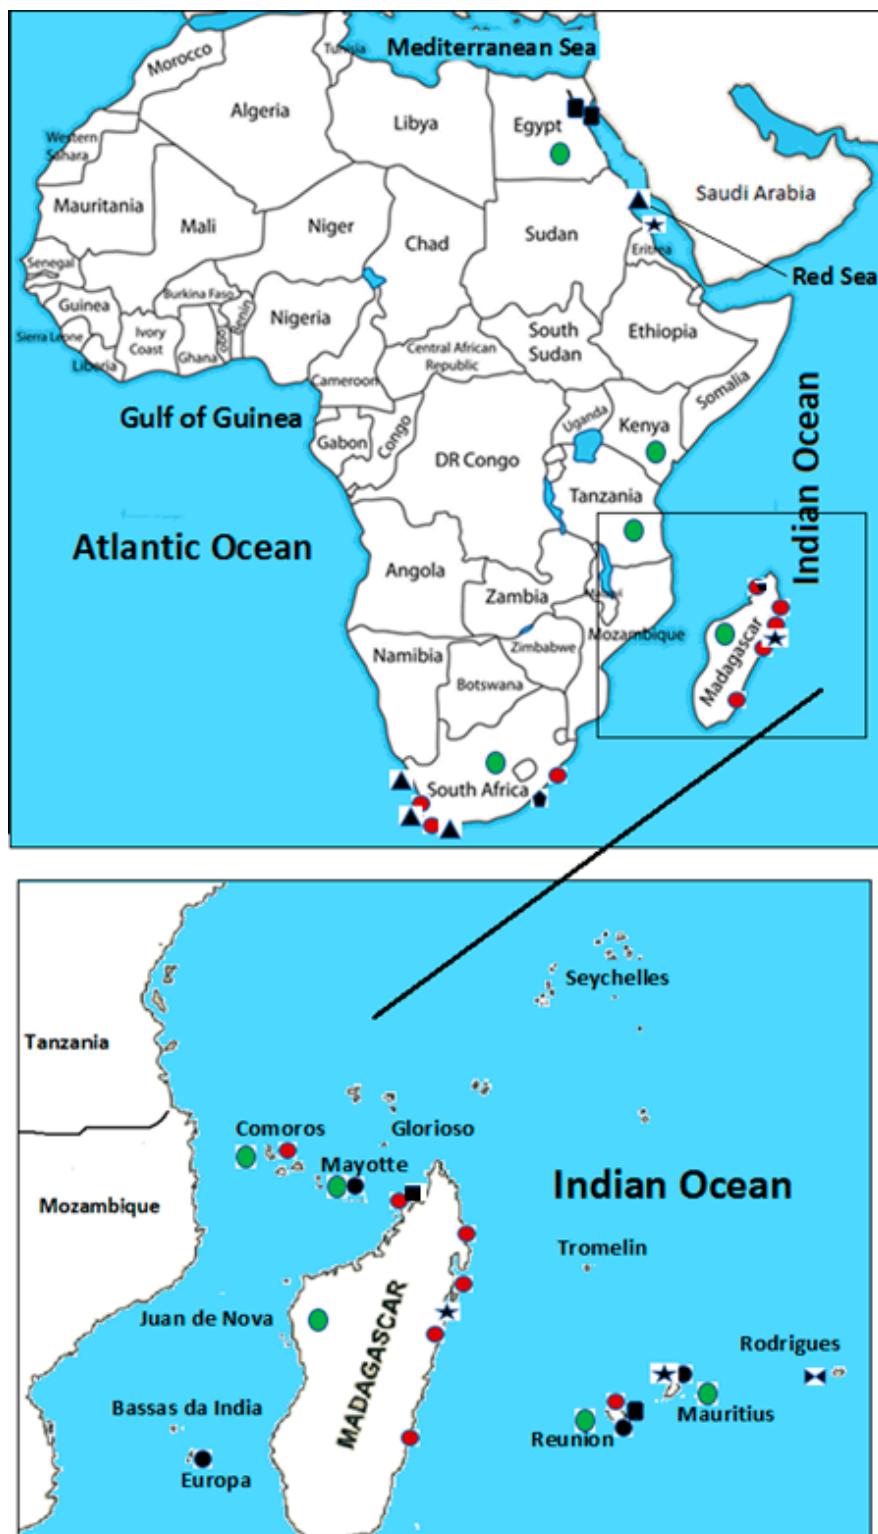

Figure 14. Map of the incidence of marine toxins (MT) along African countries of the Indian Ocean and the Red Sea, from Egypt to South Africa and nearby islands. Red circles [●]—confirmed or suspected seafood poisoning episodes caused by MT; green circles [●]—MT or Harmful Algal Blooms monitoring programmes or Centers of seafood poisonings; ▲—Saxitoxins group; ●—Okadaic Acid group; ★—Ciguatoxin group; ◆—Palytoxin group; ♦—Domoic Acid group and ■—Tetrodotoxin group.

3.1. South Africa

The occurrence of species of phytoplankton including MTs-producing HABs has been reported in coastal waters of South Africa through scientific reports and environmental monitoring programmes since 2011 [324]. Reported producer species include cyanobacteria (*Microcystis aeruginosa*, *Oscillatoria* sp., *Trichodesmium* sp.), dinoflagellates (*Dinophysis acuminata*, *D. rotundata*, *Alexandrium catenella*, *A. minutum*, *Gymnodinium* sp., *Prorocentrum* sp., *Gambierdiscus toxicus*, *Ostreopsis siamensis*, *O. ovata*, *P. lima*, *P. concavum*), diatoms (*Pseudo-nitzschia multiseries*) [19,305,309,315,331–333] and bacteria (*Vibrio parahaemolyticus*) [298]. Seafood poisoning cases were also reported in South Africa caused by PSTs, DSPs, PITXs and GYM [19,216,309,334] (Table 3) after the consumption of mussels (*Donax serra*, *Perna perna* and *Chloromytilus meridionalis*) (Table 4) [37]. To minimize seafood poisoning by MTs, South Africa has implemented, through the Department of Agriculture, a program for MT monitoring in molluscan shellfish on all coasts (South African Molluscan Shellfish Monitoring and Control Programme) [324] (Table 2). This program was created based on the regulations of the European Commission (EC) Regulation, namely: Commission Regulation (EC) No 2074/2005, No 853/2004 and No 15/2011 where limit values are described for MTs and analytical techniques are advised to monitor shellfish [324].

Due to the absence of legislation regarding CTXs, currently, there is an absence of monitoring programs regarding this group in South Africa. Since the Indian Ocean is considered an endemic site of CTXs, this is a matter of major importance.

3.2. Mozambique

Studies related to HAB occurrence in Mozambique are very scarce and the few published works indicate the occurrence of dinoflagellates of the genus *Alexandrium* [313] and species of cyanobacteria (*Phormidium ambiguum*, *Lyngbya majuscula*, and *Lyngbya cf. putealis*) [307]. To date, due to the absence of a Monitoring Program and trained health staff to recognize specific symptoms of seafood poisoning in humans, there are no records of published data of MT occurrence or reports of seafood poisoning cases in this country.

3.3. Tanzania

Published studies indicate the occurrence of cyanobacteria, namely: *Pseudanabaena* sp., *Spirulina labyrinthiformis*, *Spirulina* sp., *Leptolyngbya* sp., *Phormidium* sp., *Oscillatoria* sp., *Lyngbya aestuarii*, *Lyngbya* sp., *Lyngbya majuscula*, *Nodularia* sp., *Synechococcus* sp., *Microcystis* sp.; Dinoflagellates: *Gambierdiscus toxicus*, *Procentrum* sp. and diatoms: *Pseudo-nitzschia* sp., *Pseudo-nitzschia pungens*, *P. seriata* and *P. cuspidate* [335–341]. Data related to MTs and seafood poisoning episodes are very scarce in Tanzania. In 2003, the Tanzanian government created guidelines for investigation and control of foodborne diseases and the regulatory institution is the Tanzania Food and Drugs Authority (TFDA) (Table 2) [325]. The main objective of TFDA is to regulate matters related to food quality and safety for consumers through the dissemination of the information related to causative agents, latency period [duration], principal symptoms, typical vectors, and prevention of poisoning as measures of public health protection [325]. Among several foodborne disease sources, MTs such as CTXs, TTXs, DA, and PSTs are described by TFDA. The creation of alert and monitoring programs is an effective way to prevent poisoning episodes caused by MT-contaminated seafood.

3.4. Kenya

In order to reduce the cases of seafood poisoning caused by MTs, the Kenya Marine and Fisheries Research has carried out projects funded by governmental and non-governmental institutions for monitoring levels of HABs and their toxins (Table 2) in coastal waters and shellfish as well as the possible transfer in the trophic food web [326]. Since October 2017, there is an ongoing project called: The occurrence and distribution of HABs in East and South Africa (BIOTOXINS Research

Project] funded by National Commission for Science, Technology and Innovation (NACOSTI) at Mombasa Research Center [326]. This project will cover a period of 2 years, which is not enough for long-term monitoring. In these coastal waters were reported to occur several species of diatoms: *Nitzschia* sp., *N. closterium*, *N. longisigma*, *N. sigma*, *Pseudo-nitzschia* sp., *Guinardia* sp., *G. striata*, *G. delicatula*, *Skeletonema* sp., *Leptocylindrus* sp., *Rhizosolenia* sp., *Cerataulina* sp., *Coscinodiscus* sp., *Thalassiosira* sp., *Corethron* sp., *C. criopilum*, *C. cenofemus* and *Chaetoceros* sp.; dinoflagellates: *Alexandrium* sp., *Dinophysis* sp., *D. caudata*, *Gambierdiscus* sp., *G. toxicus*, *Gonyaulax* sp., *Gymnodinium* sp., *Gyrodinium* sp., *Ostreopsis* sp., *Peridinium* sp., *Prorocentrum* sp., *Ceratium* sp., *C. fusus*, *C. furca*, *Noctiluca* sp., *N. scintillans*, *Protoperidinium* sp., *Scrippsiella* sp. and *S. trochoidea* [301,310]. Cyanobacteria were also reported: *Lyngbya* sp., *Oscillatoria* sp., *Fischerella epiphytica*, *Anabaena* sp., *Nodularia spumigena*, *Umezakia natans*, *Aphanizomenon flos-aquae*, *Microcystis aeruginosa* and *Trichodesmium* sp. [342].

3.5. Madagascar

Madagascar is the country with more records of published data regarding MT occurrence (Figure 14) and consequently, many reported cases of seafood poisoning [36,47,49,343]. The seafood poisoning cases in Madagascar have been registered since 1930 mainly after the consumption of fish of the family *Sphyrnidae*, *Cacharidae*, *Clupeidae* (herrings, sardines), and marine turtles species (*Eretmochelys imbricata* and *Chelonia mydas*) [36,47,49,343]. The main marine poisoning causative agents reported are CTXs, TTXs, and PCTXs [18,344] (Table 4). To reduce the number of seafood poisoning events, the Madagascar Ministry of Health has created a Seafood Poisoning National Control Program (Table 2) based on the setting of an epidemiological surveillance network, prevention of the communities through educational programs and the development of research on marine eco-environment [327].

3.6. Indian Ocean French Islands

Mayotte, Europa, Banc du Geyser, Bassas da India, Glorioso, Juan de Nova, Reunion and Tromelin islands administratively make part in the French government but since they are in the Indian Ocean, were considered for the present study. In these islands, there are reports of the occurrence of HABs and cases of seafood poisoning linked to MTs. The reported HAB forming species include: dinoflagellates (*Prorocentrum lima*, *P. convacum*, *Ostreopsis ovata*, *Gambierdiscus toxicus*, *Alexandrium* spp.), cyanobacteria (*Hydrocoleum* sp., *Lyngbya majuscula*, *Phormidium* sp., *Leptolyngbya* sp. and *Oscillatoria* sp.) [70,300,317,319,345]. The recorded human intoxications were due to DSTs and TTXs [35,328] (Table 4). Centers of Disease for control and Preventing is the organization responsible for National Biomonitoring Program of toxins (PSTs) in these islands [35,328] (Table 2).

3.7. Mauritius

In Mauritius there are registered cases of seafood poisoning caused mainly by CTXs [346] after the consumption of reeffish (*Lutjanus sebae*) [70,71,71] (Table 4). The Ministry of Ocean Economy, Marine Resources, Fisheries and Shipping of Mauritius is the institute responsible for the monitoring of HABs (Table 2) [347,348], developing several activities and reporting the principal vectors species involved in seafood poisoning, namely: fish (*Variola louti*, *Plectroponus maculatus*, *ceragidae*, *Vieille loutre*, *V. plate*, *V. cuisinier*, *Lutjanus gibbus*, *L. sebae*, *L. monostigma*, *L. bohar*, *Anyperodon leucogrammicus*, *Harengula ovalis*, *Sphyraena barracuda*, *Synancela verrucosa*, *Remora remora*, *Lactoria carnuta*, *Diodon hystrix*), turtles (*Eretmochelys imbricata*), crabs (*Carpillus maculatus*), sea-urchins (*Echinothrix* sp.) and bivalves (*Tridacna* sp.) [348].

HAB producers recorded in Mauritius include several dinoflagellates species (*Ostreopsis maccarenensis*, *Gambierdiscus toxicus* Adachi & Fukuyo, *Ostreopsis ovata* Fukuyo, *Ostreopsis siamensis*, *O. maccarenensis*, *Prorocentrum lima*, *P. concavum*, *P. hoffmanianum*, *Amphidinium* sp., *A. carterae*, *Coolia* sp., *Sinophysis* sp., *Gymnodinium* sp., *Gonyaulax* sp., and *Alexandrium* sp.), diatoms (*Pseudo-nitzschia* sp.)

and cyanobacteria (*Phormidium* sp., *Oscillatoria* sp. and *Lyngbya* sp., *Phormidium* sp., *Oscillatoria* sp. and *Lyngbya* sp.) [308].

3.8. The Archipelago of Comoros

Published data of the archipelago of Comoros indicate the occurrence of *Gambierdiscus toxicus*, *G. yasumotoi*, *G. belizeanus*, *Prorocentrum arenarium*, *P. maculosum*, *P. belizeanum*, *P. lima*, *P. mexicanum*, *P. hoffmanianum*, *P. concavum*, *P. emarginatum*, *P. elegans*, *P. sp.*, *Ostreopsis caribbeanus*, *O. mascarenensis*, *O. ovata*, *O. heptagona*, *O. labens*, *O. siamensis*, *O. lenticularis*, *O. marinus*, *Cooliamonotis*, *C. tropicalis*, *Sinophysis microcephalus*, *S. canaliculate* and *Amphidiniopsis* sp. [10,300]. Suspected seafood poisoning episodes linked to MTs were registered in the archipelago of Comoros after the consumption of turtle *Eretmochelys imbricata* with symptomatology similar to CFP [26], suggesting the presence of CTXs (Table 4).

3.9. Somalia and Seychelles

There are no published studies related to the occurrence of HABs and MTs in Somalia and Seychelles. While there are no published reports of HABs or MTs in Somalia and Seychelles waters, the proximity to other countries with such reports and currents in the area suggest that investigations are necessary to avoid potential seafood poisoning events [62].

Table 3. Geographic occurrence MT per country, MT producer, and MT vector along African countries of the Indian ocean and red sea coasts. TX - toxin.

3.10. Mediterranean and Red Sea (Djibouti, Eritrea, Sudan, Egypt)

Several research works related to MTs are carried out in the Red Sea but are very limited on the African coast. Saudi Arabia is the country with the most published studies related to the occurrence of HABs along the Red Sea [13,308,311,316,321,322,352,353]. The Dinoflagellates (*Alexandrium* sp., *Dinophysis* sp., *Prorocentrum* sp., *Pyrodinium* sp., *Gymnodinium* sp.), cyanobacteria (*Lyngbya* sp., *Oscillatoria* sp., *Trichodesmium* sp.) and diatoms (*Pseudonitzschia* spp.) are the most reported marine producer species [13,308,311,316,321,322,352,353]. The bacteria *Vibrio paraheemolyticus*, producer of TTX, was detected in shrimp (*Penaeus latisulcatus*) in the Suez Gulf [299]. MTs reported in the Red Sea, mainly the Egyptian coast, described in Tables 3 and 4, include CTXs, TTXs, PSTs detected in puffer fish such as *Pleurana canthus sceleratus* and *Lagocephalus sceleratus* [13,316,349–353]. Cases of seafood poisoning caused by CTXs and TTXs were reported, and according to the Poison Control Center, affiliated with Ain Shams University (Cairo, Egypt), CTXs are the third most responsible agents that induce food poisoning in Egypt [354]. Puffer fish poisoning has been recorded since ancient Egyptian times [42]. In Egypt, there is monitoring of HABs in aquatic ecosystems since 1994 when Egypt became a member of the Convention on Biological Diversity although the Nature Conservation Sector, Egyptian Environment Affairs Agency and the Ministry of State for Environmental Affairs (Table 2) are focal points [330]. There are no reports of HABs and MT occurrence in coastal areas of Djibouti, Eritrea, and Sudan.

Table 4. Seafood poisoning episodes caused by MTs, observed effects/Symptoms, fish or shellfish consumed and victim number affected along African countries of the Indian Ocean and Red sea coasts. TX - Toxin

Local	Date	Seafood	Observed Effects/Symptoms	TX	Detection Method	TX Concentration, (mg TX Equivalents/Kg Shellfish Meat)	Victim Number	Reference
Comoros islands: Ndronndroni	24 December 2012	<i>Eretmochelys imbricata</i> (turtle)	Itching, Asthenia, Vomiting, Abdominal pain, Rash Myalgia Shortness of breath, Nausea Itching of the mouth/throat, Fever, Diarrhea Vertigo, Paresthesia, Dysphagia Mouth burn Sore throat, Erectile dysfunction	-	-	-	49 suspected cases and 8 probable cases, age range [0–40 years], 1 death	[26]
North-eastern coast of Madagascar	December 1994	Turtle	Nausea, vomiting, dysphagia, acute stomatitis	-	-	-	60 persons with poisoning attack rate were 48% with a lethality of 7.7%	[47],
Madagascar: district of Fenoarivo Atsinanana	November 2013	<i>Carcharhinus leucas</i> (shark)	Paresthesia of the extremities, dysesthesia, and reversing sensitivity of hot and cold accompanied by a headache, dizziness, and arthralgia between 2 and 12h after ingestion	CTXs	MBA	0.083 P-CTX-1	124 people, 9% deaths	[20]
Madagascar: Antalaha District	January 1994	<i>Herklotischthys quadrrimaculatus</i> (Fish)	Malaise, uncontrollable vomiting, diarrhea, tinglings of extremities, delirium and death	PTXs	CBA	0. 09272 P-CTX-1	Death of one adult	[18]
					MBA	0. 00045 PTXs/fish [head and esophagus]

Madagascar: Nosy Be Island	July 1998	-	-	TTXs	MBA	16 MU/g (no data to convert to mg/Kg)	4 people, one death	[41]

Table 4. Cont.

Local	Date	Seafood	Observed Effects/Symptoms	TX	Detection Method	TX Concentration, (mg TX Equivalents/Kg Shellfish Meat)	Victim Number	Reference
Madagascar: Manakara district	November 1993	<i>Carcharhinus amboinensis</i> [shark]	Deep coma and death, body rigidity due to loss of cerebral function, myosis, mydriasis, convulsions, Respiratory distress due to acute pulmonary edema, cardiovascular collapse, bradycardia, gengivorrhagia Dehydration, paresthesia on fingertips and toes, dizziness, pruritus, narcosis, faintness, hyperthermia, ataxia asthenia, dehydration, cephalalgia, diarrhea, epigastralgia, laryngeal distress	CTXs	Ciguatera poisoning Symptomatology	-	500 people, 20% deaths	[21]
South Africa: Cape Town	May 1978	<i>Choromytilus meridionalis</i> [Mussel]	Paraesthesia of en fingers/hands, Circumoral paresthesia, paranesthesia of toes/feet, Vertigo, Floating sensation, Ataxia, Weakness of upper, Weakness of lower limbs and Dysarthria A headache	PSTs	MBA	72.83 STX	17 people, no deaths	[39]
South Africa: Natal coast	December 1957	<i>Mytilus meridionalis</i> [Mussel]	peculiar lightness of the body, with a tingling around mouth, finger, and toes; no moving; feeble inarticulate noise;	PSTs	MBA	0.04 STX	5 people and one cat	[40]
South Africa: Table and False Bays	1888	<i>Donax serra</i> [Mussel]	-	-	-	-	-	
South Africa: Cape Town	April 1948	<i>Donax serra</i> [Mussel] and <i>Chloromytilus meridionalis</i> [Mussel]	-	-	-	-	One death	[37]
South Africa: Natal coast	December 1957	<i>Perna perna</i> [Mussel]	-	-	-	-	5 people, one death	
South Africa: Cape Town a	May 1958	<i>Chloromytilus meridionalis</i> [Mussel]	-	-	-	-	One death	
Reunion Island	September 10th, 2013	<i>Lagocephalus sceleratus</i> [fish]	peri-oral paresthesia, weakness of both lower limbs, paresthesia all over the body, headache, dyspnea, nausea and vomiting, blurring of vision, and vertigo	TTX	MBA	Liver: 17 TTX Flesh: 5 TTX	10 people	[35]

4. Final Considerations and Recommendations

African Indian Ocean and the Red Sea coasts have a subtropical and tropical climate, considered optimal for the development and transportation of several HAB-forming species, and consequently, the production of MTs. Paradoxically, studies related to the occurrence and incidence of HABs and MTs are very limited, from South Africa to Egypt. From a few data available in this zone, most describe only the genus and not the full species, making it very difficult to evaluate the occurrence of the toxic species. The most reported HAB phytoplankton in this region are cyanobacteria, followed by dinoflagellates, and diatoms as potential MT producers. Relative to MTs, the most reported and involved in seafood poisoning episodes include CTXs, PSTs, and TTXs. The scarcity of the data related to MTs suggests the need for further studies and the creation of specific monitoring programs of HABs, particularly for dinoflagellates and diatoms since these constitute the phytoplankton that produces more fatal MTs, though in recent years several genera of bacteria have been described as producers of a potent group of marine toxins, TTXs, which have already been detected on the African coasts of the Indian Ocean and Red Sea. The main MTs that must be monitored in shellfish are presented in Table 5. Analytical techniques such as LC-MS/MS are advised and recommended as determination and quantification methods due to their higher reproducibility, specificity, sensitivity and capacity to discriminate analogs of given toxins in the sample. The permitted limit of a toxin in shellfish can be adopted from other countries as an example to follow such as the EU region, USA, Japan, Australia, and New Zealand.

Table 5. Recommended marine toxins to be monitored and suggestion of permitted limit to be used.

Toxin	Syndrome	Permitted Limit, mgKg ⁻¹	To be adopted from
STX	PSP	0.8 STXeq	EU region
CTX	CFP	0.00001 P-CTX-1eq	USA
YTX	-	3.75 YTXeq	EU region
PTX	-	0.16 OAeq	EU region
TTX	-	2 TTeq	Japan
DA	ASP	20 DAeq	EU region
OA	DSP	0.16 OAeq	EU region
AZA	AZP	0.16 AZAeq	EU region
PITX	-	0.25 PITXeq *	EU region
PbTx	NSP	0.8 TX-2 eq	USA, New Zealand, and Australia

* This toxin is not monitored and 0.25 PITXeq was proposed in the first meeting (Cesenatico, Italy, 24–25 October 2005) of the working group on Toxicology of the national reference laboratories [NRLs] for Marine Biotoxins.

For the success of the MT monitoring programs, the integration and intercollaboration of environmental, public health and researches institutions and universities of the all African Countries of the Indian Ocean and the Red Sea is crucial.

Author Contributions: Conceptualization, V.V. and M.S.; Writing-Original Draft Preparation, I.J.T.; Writing-Review & Editing, I.J.T., M.S. and V.V.; Supervision, V.V. and M.S.

Funding: This research was supported by the project Alertox-Net [EAPA-317-2016] of the Interreg Atlantic Area Program funded by the European Regional Development Fund and by the Portuguese Foundation of Science and Technology [FCT] project UID/Multi/04423/2013.

Acknowledgments: We acknowledge the project EMERTOX [grant 734748], funded by H2020-MSCA-RISE 2016.

Conflicts of Interest: The authors declare no conflict of interest.
