**Abstract:** Physical exercise (PE) is recommended for Rheumatoid Arthritis (RA), but the molecular and biological mechanisms that impact the inflammatory process and joint destruction in RA remain unknown. The objective of this study was to evaluate the effect of PE on the histological and transcriptional changes in the joints of adjuvant-induced arthritis (AIA) rat model. AIA rats were subjected to PE on a treadmill for eight weeks. The joints were subjected to histological and microarray analysis. The differentially expressed genes (DEGs) by PE in the arthritic rats were obtained from the microarray. The bioinformatic analysis allowed the association of these genes in biological processes and signaling pathways. PE induced the differential expression of 719 genes. The DEGs were significantly associated with pathogenic mechanisms in RA, including HIF-1, VEGF, PI3-Akt, and Jak-STAT signaling pathways, as well as response to oxidative stress and inflammatory response. At a histological level, PE exacerbated joint inflammatory infiltrate and tissue destruction. The PE exacerbated the stressed joint environment aggravating the inflammatory process, the hypoxia, and the oxidative stress, conditions described as detrimental in the RA joints. Research on the effect of PE on the pathogenesis process of RA is still necessary for animal models and human.

**Keywords:** running; exercise; physical activity; rheumatoid arthritis; adjuvant-induced arthritis

## 1. Introduction

Rheumatoid arthritis (RA) is one of the most common inflammatory arthritis affecting 0.5–1.0% of the population [1]. RA is a systemic autoimmune disease characterized by inflammation of the synovial membrane and periarticular structures. Joint pain, stiffness, and swelling are the primary symptoms, which eventually lead to joint deformity and functional disability. Extra-articular manifestations, including cardiovascular, pulmonary, psychological and skeletal disorders are common in RA patients [2]. The etiology and pathophysiology of RA remain unresolved; however, genetic and environmental factors have been associated with the inappropriate immunomodulation that triggers the inflammatory process in the joints and the subsequent damage to synovial structures [3]. The treatment of RA aims to reduce pain and inflammation in the joints and also to preserve their structural integrity and the patient's functionality. Currently, treatment includes a variety of pharmacological agents, education programs, joint protection, lifestyle changes, PE and surgical intervention as a final step [4–6].

PE is considered in the multidisciplinary management of RA patients. The European League Against Rheumatism (EULAR) has established the recommendations for physical activity in people with inflammatory arthritis [4], and its recommendations for cardiovascular disease risk management in RA include regular exercise [7]. It has been previously shown that PE improves joint health [8], muscle strength [9], cardiovascular fitness [10], vascular function [11], and psychological well being [12]. PE also reduces the inflammation [13], rheumatoid cachexia [14], and fatigue [15] in RA patients.

Although the systemic benefits of PE in rheumatic patients are well recognized, the direct consequences of PE in active synovitis and the potential role of PE accelerating joint destruction are not clear. Some reports have shown that mechanical load influences the onset and worsens the progression of the disease in experimental animal models of arthritis [16,17]; therefore, the consequences of PE on inflamed joints remain a topic that should be addressed.

We selected adjuvant-induced arthritis (AIA) because it mimics the signs and symptoms of human RA, such as the histopathological changes of inflammation, vascular proliferation, and importantly, the progression to joint destruction [18]. The AIA model has been widely used in the development of antirheumatic drugs, including several non-steroid anti-inflammatories, methotrexate [19], and also biologic drugs, including tocilizumab [20] and Jak-inhibitors like tofacitinib [21].

To understand the effects of PE in the complexity of the inflamed joint, we selected an unbiased approach to maintain a broad perspective. We selected the bioinformatic analysis of the transcriptome from the tarsal joint through a DNA microarray. The microarray simultaneously evaluates the expression levels for a large number of genes [22]; and, identifies the most relevant mediators in complex processes such as the interplay between PE and inflammation.

A better understanding of the molecular consequences of PE on the inflamed joints may contribute to improving its prescription for RA patients for the protection of joint integrity. In this regard, the objective of this study was to determine the effect of an exercise intervention on the transcriptional expression of genes in the AIA rat model using microarray technology.

## 2. Materials and Methods

### 2.1. Animals and Study Groups

Male Wistar rats (300–350g) were used for this study. The animals were housed in an animal facility with a 12 h light/dark cycle maintained at temperatures between  $22 \pm 1$  °C with food and water provided *ad libitum*. The experimental protocol was approved by the Committee of Ethics of the Instituto Chihuahuense de Salud-Secretaría de Salud-Facultad de Medicina y Ciencias Biomédicas, UACH (protocol number CEI-EXP-140/15). The animals were randomly divided into two groups of seven animals each: (1) arthritis group and (2) arthritis-exercise group.

### 2.2. Arthritis Induction

The AIA model was conducted as previously reported [23]. Rats were injected in the footpads with 0.2 mL of Complete Freund's Adjuvant (CFA) (Sigma Chemicals, St. Louis, MO, USA) mixed with phosphate buffer saline in the 1:1 ratio. To increase the severity of arthritis, a booster injection with 0.1 mL of the emulsion was administered in the same way on day 5–post first injection.

### 2.3. Familiarization

Animals belonging to the arthritis-exercise group were familiarized with the treadmill for three weeks to reduce their stress level during the PE. Each daily familiarization session included placing the rats on the treadmill switched off for 10 min (visual/olfactory adaptation) and then turning on the treadmill at the minimum speed (3 m/min) for 5 min (sound/movement adaptation). After the first week of the treadmill familiarization, arthritis induction was started and the familiarization period continued for two more weeks.

#### 2.4. Physical Capacity Test

After the familiarization, a physical capacity test (PCT) was conducted to establish the maximum speed reached by the animals before the intervention of PE. The PCT consisted of a single treadmill session in which the rats, after 5 min of warm-up (3 m/min), ran in the band with an increase in the speed of 3 m/min every 2 min until they fatigued and stopped running. The maximal physical capacity (100%) was defined as the maximum speed reached by each animal. The average speed per group was calculated, and this was used to establish the speed of the exercise sessions.

#### 2.5. Exercise Program

The rats were exercised three times a week for eight weeks. The exercise started with a speed of 20% of the PCT and increases of 13% in speed were applied every two weeks until reaching 60%. Each exercise session included four phases: (1) acclimatization: rats were placed on the treadmill switched off for 5 min; (2) warm-up: rats walked for 5 min at lowest speed; (3) exercise: rats run for 25 min at the corresponding speed; and (4) cool down: rats walked at lowest speed for 5 min. The exercise sessions were administered at the same time each day.

#### 2.6. Histological Analysis

After exercise intervention, the rats were euthanized, and the tarsal joints were immediately dissected. The ankle, the subtalar and the navicular cuboid joints were extracted and cut proximally in the distal fibula and tibia; and, distally in the metatarsal bones at the diaphysis. The muscle was dissected as much as possible and the synovial and ligament structures were preserved and fixed in 10% formalin phosphate buffer for 48 h and decalcified with 5% nitric acid for 24 h [24]. The tissues were dehydrated in graded ethanol, and embedded in paraffin, sectioned, and stained with hematoxylin-eosin (H&E Merck, Darmstadt, Germany). The histological variables: (a) inflammatory infiltrate, (b) synovial hyperplasia, (c) pannus formation, (d) synovial vascularity, (e) cartilage damage and (f) bone erosion were semi-quantitatively evaluated using a scale of 0 = absent, 1 = mild, 2 = moderate and, 3 = severe on each animal. The maximum score reached per animal for each parameter was 12 when the four joints showed a severe level. The scoring average per study group was estimated. The histological variables were evaluated by two experienced operators blinded to the different groups.

#### 2.7. DNA Microarray and Bioinformatics Analysis

The effect of PE on transcriptome was evaluated in the DNA microarray by comparing the arthritis-exercise group (experimental group) and the arthritis group (reference group). The tarsal joints dissected were immediately placed in liquid nitrogen and disrupted with mortar and pestle. Total RNA was extracted using RNeasy<sup>®</sup> Lipid Tissue Mini Kit (QIAGEN, Germantown, MD, USA) according to the manufacturer's instructions. The RNA quality and integrity were verified using a 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA). For the microarray, the RNA of every group was pooled keeping equimolar quantities of every individual.

The microarray analysis was performed at the Institute of Cellular Physiology of the National Autonomous University of Mexico (México City, México). Briefly, the cDNA was synthesized and labeled for subsequent hybridization in the Rn5K microchip containing 5000 rat genes. Scanning and signal acquisition was performed using the ScanArray 4000 (Packard BioChips Technologies, Billerica, MA, USA). The GenArise software was used for the analysis of the microarray scan, and the lists of DEGs [Z-score  $\geq 1.5$  standard deviations (SD)] were obtained. To assess the biological relevance of the DEGs, DAVID Bioinformatics Resources 6.8 platform (<https://david.ncifcrf.gov/>) was used. Gene Ontology (GO) and KEGG (Kyoto Encyclopedia of Genes and Genomes) pathway mapper with significant associations ( $p \leq 0.5$ ) were obtained [25]. Also, the STRING 10.5 database (<http://string-db.org/>) was used to obtain the analysis and integration of direct and indirect protein-protein interactions (IPP)

centered on the functional association [26]. The DEGs identified in the microarray were loaded, and the interactions were selected with minimal confidence (interaction score > 0.4). The obtained IPP network was analyzed more thoroughly to obtain primary clusters of sub-networks using the Cytoscape software version 3.7.0 (Bethesda, Rockville, MD, USA) with the Molecular Complex Detection (MCODE) complement [27,28].

### 2.8. Statistical Analysis

The statistical analysis was made in SPSS statistics v22 software (SPSS Science Inc., Chicago, IL, USA). Measures of central tendency were estimated for each variable. T-test was used to compare the effect of PE on histological parameters. Differences were considered significant when  $p < 0.05$ .

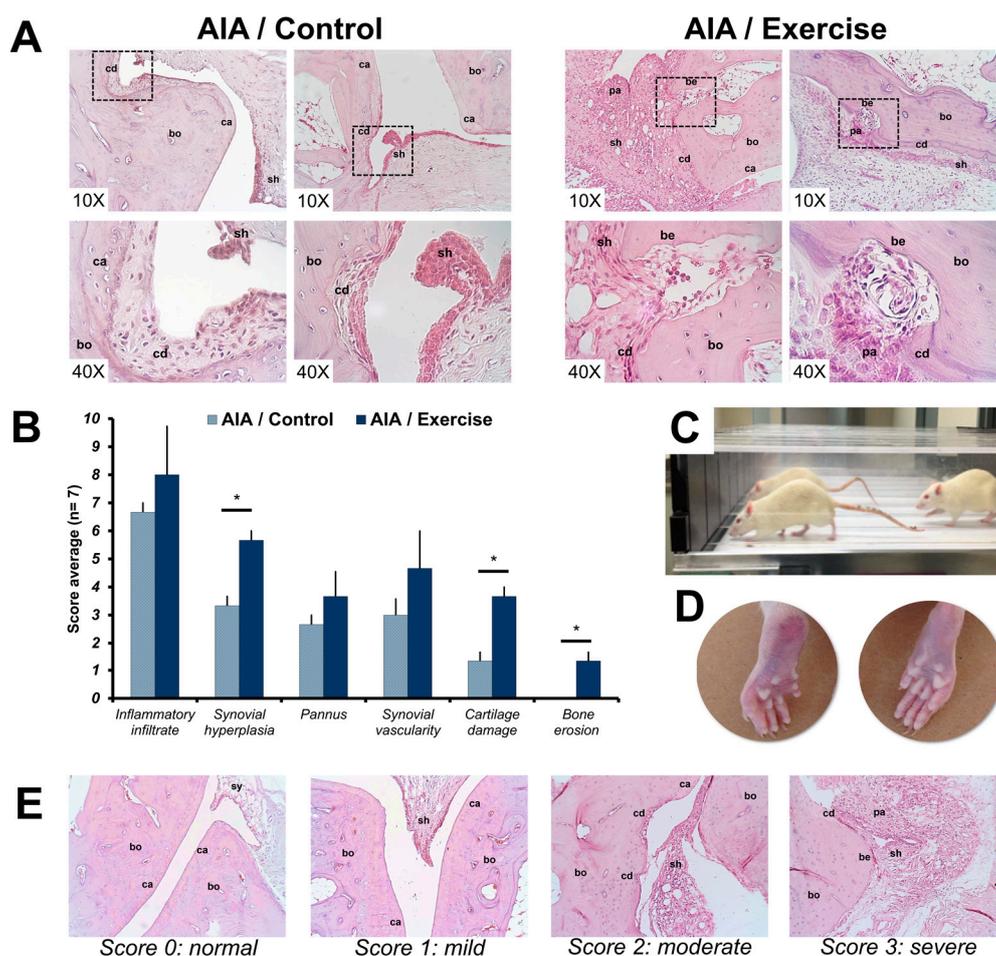

## 3. Results

### 3.1. Maximal Physical Capacity

The maximal physical capacity obtained in the PCT for the arthritis-exercise group was  $21.28 \pm 5.96$  m/min. The initial speed and its increments along the exercise intervention were based on this value.

### 3.2. Histological Analysis

The effect of exercise in the joints was histologically evaluated using H&E staining. The scores of inflammatory infiltrate, synovial hyperplasia, pannus formation, synovial vascularity, and cartilage and erosions obtained for each study group are shown in Figure 1. The highest scores of all evaluated parameters were reached in the arthritis exercise group. However, only hyperplasia, cartilage damage and bone erosion were statistically different between the groups.

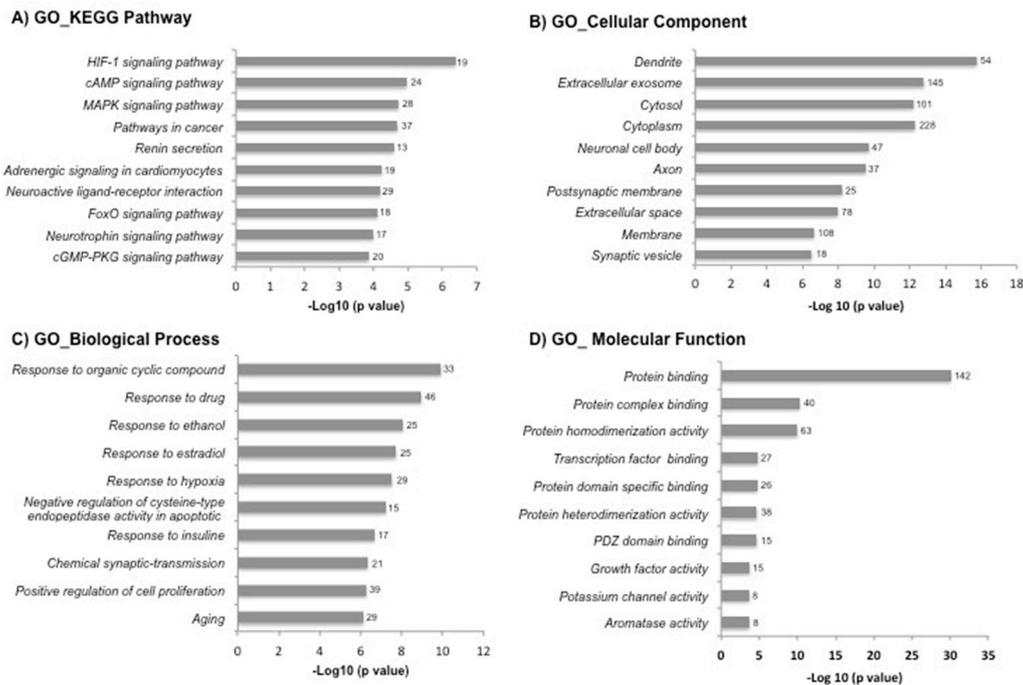

**Figure 1.** Effects of exercise on tarsal bone histological parameters in adjuvant-induced arthritis rats. (A) Representative images of histological findings in the tarsal joints of the study groups at the end of the exercise intervention using H&E staining. (B) Joint involvement was scored by the semi-quantitative scale (showed in E) to describe inflammatory changes and structural remodeling in the tarsal joints (7 rats per group). The t-student test was used to compare histological measurements between groups. \*  $p < 0.01$ . (C) Exercised rats on a treadmill. (D) Representative images of clinical changes on hind paws of adjuvant-induced arthritis (AIA) rats exercised (left) and non-exercised (right). (E) Representative images of the inflammation and structural joint damage scores in the tarsal joints of AIA rats. The 0 (normal) score was established in healthy rats, where the bone (bo), cartilage (ca) and synovium (sy) did not show alterations. The arthritis scores 1 (mild), 2 (moderate), and 3 (severe) were based on the inflammatory changes: the presence of synovial hyperplasia (sh) and pannus (pa) and structural remodeling: cartilage damage (cd) and bone erosion (be). The images were acquired with a 10× and 40× amplification. AIA: adjuvant-induced arthritis.

### 3.3. Microarray and Bioinformatic Analysis

The transcriptome-wide microarray analysis identified a pool of DEGs in the joints from arthritic exercised rats in comparison to arthritic non-exercised rats. A total of 719 genes were differentially expressed ( $Z$ -score  $\geq 1.5$  SD), 361 up-regulated (Appendix A), and 358 down-regulated (Appendix B). AB000928 (Zp1) and X68101 (Trg) were the most significantly up- and down-expressed genes by PE, respectively.

To understand the related biological functions of the 719 DEGs, we used the DAVID database for the enrichment analysis of GO and KEGG pathways. The top 10 enriched terms of GO and KEGG pathways are shown in Figure 2. Response to organic cyclic compound, response to drug, and response to ethanol were among the top enriched biological processes. The DEGs were enriched in molecular

functions like protein binding. The most enriched KEGG pathways included hypoxia-induced factor-1 (HIF-1), cyclic adenosine monophosphate (cAMP) and mitogen-activated protein kinase (MAPK) signaling pathways. Subsequently, we selected the biological processes and KEGG signaling pathways known to be relevant in the pathogenesis of RA, which included: response to hypoxia, response to oxidative stress, angiogenesis and inflammatory/immune response (Table 1).

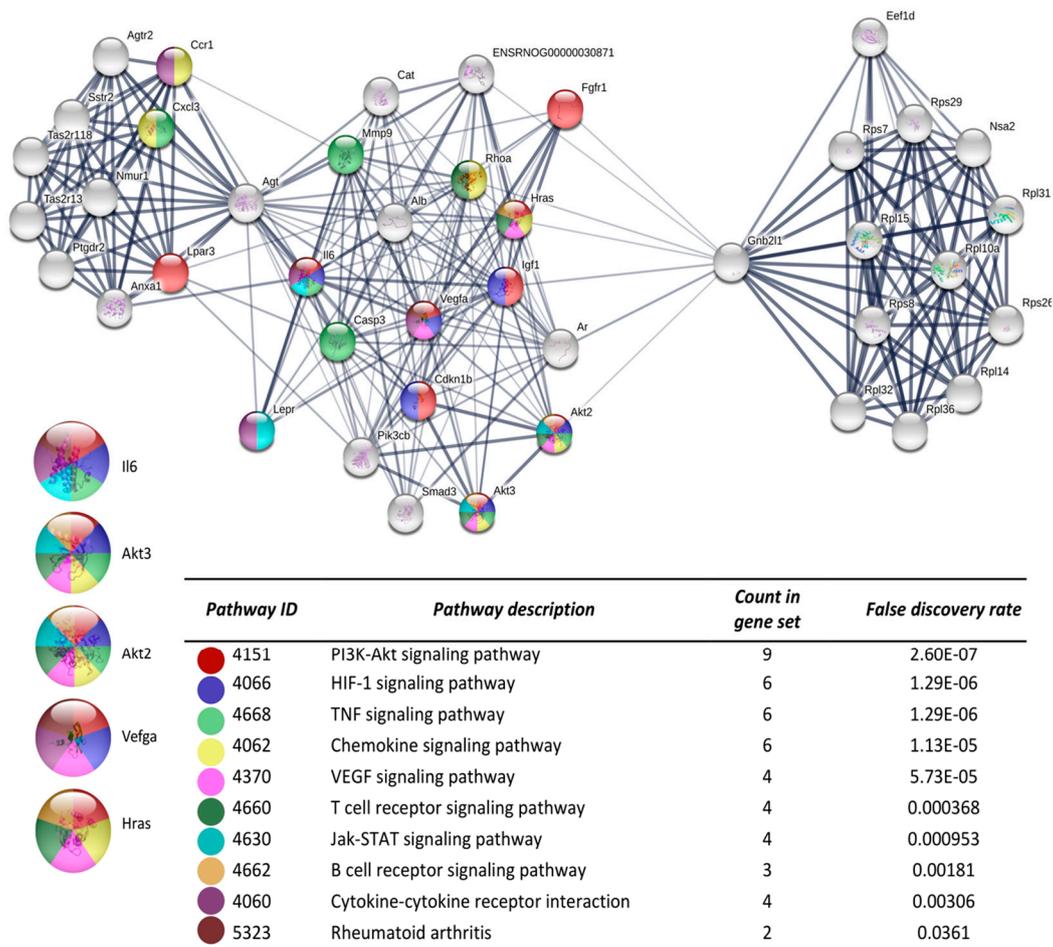

**Figure 2.** The Gene Ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis of differentially expressed genes in the DAVID database. The 719 differentially expressed genes by exercise were uploaded into the DAVID database for enrichment analysis. The top 10 GO analysis results of these dysregulated genes were displayed in the bar chart: (A) KEGG pathway, (B) cellular component, (C) biological process and (D) molecular function. The bars indicated the  $-\text{Log}_{10}(p \text{ value})$  of each GO and KEGG term. The number of genes involved in each term is shown on the right side of each bar.

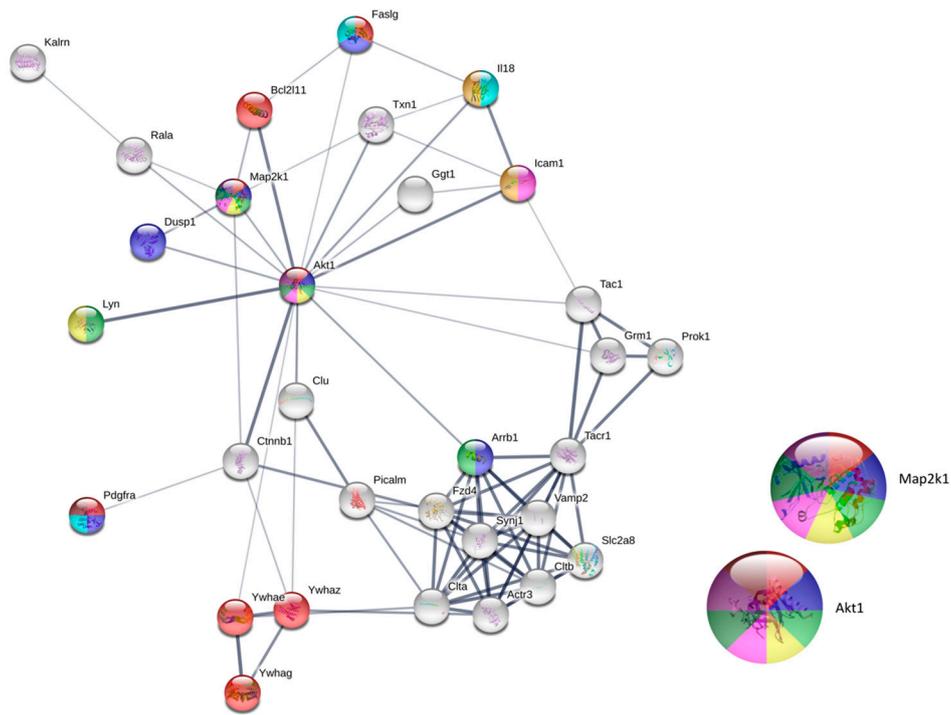

After the analysis on DAVID, the list of the 719 DEGs was analyzed on the STRING and Cytoscape-MCODE platforms. The first three clusters obtained are shown in Figures 3–5. The genes from the first three clusters were loaded in STRING to identify the associated KEGG signaling pathways; those relevant in RA were selected and marked with different colors. The pathways considered as relevant included the HIF-1 signaling pathway. The analysis of the protein networks unveiled relevant genes dysregulated by PE. Those presented multiple functional connections included up-regulated genes such as serine-threonine protein kinases Akt1, Akt2, and Akt3; the vascular endothelial growth factor A (Vefga), the mitogen-activated protein kinase kinase 1 (Mapk1), phosphatidylinositol 4,5-bisphosphate 3-kinase catalytic subunit beta isoform (Pik3cb), glucokinase (Gck), fructose-biphosphatase2 (Fbp2); and also down-regulated genes such as interleukin 6 (Il6).

#### 4. Discussion

Current evidence describing the influence of PE on the pathogenic mechanisms of the arthritides is scarce and limited to studies in animal models. Most of these studies have focused on animal models of osteoarthritis and, in most cases, only clinical and histological parameters have been evaluated, limiting our understanding of the PE in the pathogenesis of active synovitis. To our knowledge, no previous study has assessed the effects of PE on the transcriptome profile in the AIA model.

Our study shows that PE induced several genes linked to RA pathogenesis. Specifically, PE exacerbated hypoxia, oxidative stress, and the immune/inflammatory response in rats with AIA. The histology confirms our transcriptome results; in the joints of the exercised animals, we observed an increase in the inflammatory infiltrate and more severe scores for bone and cartilage destruction.

In our opinion, the connection between PE and its potential detrimental role at active stages of synovitis should be considered as a relevant event in patients with inflammatory arthritides. Current recommendations for physical activity and PE in people with inflammatory and non-inflammatory arthritis [4,5,7,29] have been established mostly on clinical studies in humans, which the intimate effect of PE in the arthritic joints at a molecular level has not been considered. These recommendations have not been specified according to the disease activity; however, as our study shows, likely at very active stages of inflammatory arthritides, PE could increase the inflammatory process. It is unlikely that PE will be prescribed in patients with active arthritis; however, a wide prescription of PE could

also include the large proportion of patients whom remain with some degree of inflammatory activity despite therapy. Probably, the PE benefits may not be as clear in those patients with partial disease control. Therefore, the disease activity should be considered as an element for PE prescription.

RA pathogenesis remains a primary research field; we now understand that the rheumatoid pannus is an altered microenvironment that carries a significant array of abnormal immune processes and also several metabolic alterations. The increase in hypoxia and oxidative stress are recognized as relevant inflammation drivers within the rheumatic synovium. Their pathological implications are now sustained by experimental results both: in animal models [30,31] and human disease [32,33]. Synovial hypoxia promotes inflammation, angiogenesis, production of chemokines, and cartilage and bone destruction, mediated in part, through HIF-1 that is a potent pleiotropic mediator [32,34].

Our study confirms that PE up-regulates genes linked to hypoxia and oxidative stress in the arthritic joints; indeed, the HIF-1 signaling was the first enriched pathway in our bioinformatic analysis, suggesting that this pathway was the strongest influenced by the PE. Downstream HIF-linked genes as the vascular endothelial growth factor (VEGF) are also up-regulated. VEGF is critical for the onset and perpetuation of vascular proliferation in synovitis [35–37]. Also, it was previously reported the VEGF increase in the serum and synovial fluid of RA patients [35,38] as well as in experimental animal models [39].

Hypoxia could activate the genes encoding nearly every step of glycolysis [32]. Abnormal glucose metabolism was observed in the synovial fluid and synovium of RA, which is evidenced by increased glycolytic enzyme activity [40]. A recent study proposes the inhibition of hexokinases as a potential therapeutic strategy in the treatment of patients with RA [41]. According to this, the glucokinase (Gck) and the hexokinase 1 (Hk1) were up-regulated by PE in our study. Additionally, genes involved in the oxidative stress process were also dysregulated by PE. It is recognized that in an inflamed joint, hypoxia and reperfusion cycles occur, producing an excessive amount of reactive oxygen species (ROS) known as oxidative stress [33,42].

In addition to hypoxia and oxidative stress conditions induced by the effect of PE, other KEGG pathways were dysregulated (Table 1) such as rheumatoid arthritis, T-cell and B-cell receptor signaling, chemokine, Jak-Stat, TNF, Toll-like-receptor, WNT and osteoclast differentiation signaling pathways. This array of dysregulated pathways suggests a widespread effect of PE both in the adaptive and innate immune response.

Other genes participating in several KEGG pathways in our study include Akt1, Akt2, Akt3, Map2k1 and Plk3cb which belong to PI3K/AKT/mTOR and MAPK pathways that are considered central in RA pathogenesis [43,44]. They have been implicated in fibroblast-like synoviocyte proliferation and activation. They stimulate the production of pro-inflammatory and osteoclastogenic cytokines; besides, the inhibition of either pathway has been correlated with the improvement of disease activity parameters. Therefore, the use of agents with the potential to regulate either PI3K/AKT/mTOR or MAPK pathways has been considered as a potential therapeutic strategy [45].

The molecular results of the PE effect are not easily comparable with previous studies due to the low number of reports, which had objectives aimed at particular aspects of the disease. However, we can distinguish that the negative effect of PE has also been reported in the two most recent and complete studies in this field [16,17]. The results of these studies suggest a direct link between the degree of mechanical stress to inflammation and tissue localization, which strengthens previous studies that propose biomechanical factors as potential determinants for the topographic pattern of joint disorders in arthritis [46]. Cambré et al., suggest that the link between mechanical stress and the onset of arthritis is explained by local recruitment of Ly6high inflammatory cells elicited by mechanostress-induced chemokine induction in resident mesenchyme cells [17]. They also provide evidence of the local participation of the complement activators to maintain the progression and chronicity of arthritis through an impaired resolution [16].

On the other hand, it has been shown that in healthy rats, PE has a positive effect in the joints it induces extracellular matrix biosynthesis, cartilage strengthening, and attenuation of inflammatory

pathways [47]. This suggests that the gene induction pattern of mechanosensitive genes seems to be distinct between different arthritis models and healthy animals, and likely also in regarding to the degree of arthritis activity.

Consistent with the genetic analysis, our histological findings showed that PE had an adverse effect on increasing the inflammatory infiltrate and the joint destruction. In experimental models of arthritis, it has been confirmed that mechanical stress increase joint inflammation, stimulate the progression and chronicity of arthritis and structural damage [16,17,48]; besides, the mechanical stress decrease the bone quality [16]. In contrast to our findings, other studies in the AIA model have shown an anti-inflammatory effect of PE in some parameters such as synovial hyperplasia [49,50], and joint destruction [51].

Mode, intensity, frequency, timing, and duration of the PE protocol are decisive aspects to the physiological responses and different outcomes [52]. Moreover, the severity of arthritis at the starting time of PE could be definitory. Studies in the AIA model that started the PE at the pre-arthritis stage [49,50] showed beneficial results. However, we started the PE at an arthritic stage because we think this scenario is more representative of RA patients.

## 5. Conclusions

The present study explored the influence of PE in the genetic expression and the histology of the actively swollen joints in the AIA model. Our results describe an exploratory and preliminary scenario in which PE increased the expression of genes with a known pathogenic role in RA; these findings were consistent with the histological findings. These results suggest that the PE exacerbated the stressed joint environment, where the inflammation, hypoxia, and the oxidative stress prevail, rendering clear parallels to the RA joints. The molecular effect of exercise on active stages of inflammatory arthropathies requires further studies in animal models and humans, which could contribute with the development of adequate programs for RA patients that can ensure a beneficial effect without negative implications at the tissue level.

**Acknowledgments:** The authors thank Lorena Chávez, José Luis Santillán, Simón Guzmán and Jorge Ramírez for the microarray analysis. Likewise, the authors thank Rogelio González and Adrián Chávez for their support in the design and construction of the software used in this research.

**Conflicts of Interest:** The authors declare no conflict of interest.

## Appendix A. List of Genes Up-Regulated by PE Effect

Gene Id	Gene	Z-Score
AA818786	No data	1.770223
AA963507	No data	1.500387
AB000928	zona pellucida glycoprotein 1(Zp1)	3.330347
AB003753	No data	2.348897
AB012139	bone morphogenetic protein 1(Bmp1)	1.717532
AB022014	proteasome 26S subunit, non-ATPase 10(Psm10)	1.800734
AB024333	barrier to autointegration factor 1(Banf1)	2.409521
AB027143	septin 5(Sept5)	2.332071
AB037248	ATPase H <sup>+</sup> transporting V0 subunit e1(Atp6v0e1)	1.790973
AB041723	apoptosis inducing factor, mitochondria associated 1(Aifm1)	2.20147
AB043959	ubiquitin C-terminal hydrolase L3(Uchl3)	2.083474
AB070355	kinesin family member 1B(Kif1b)	2.560659
AB073318	brain and acute leukemia, cytoplasmic(Baalc)	1.825273

Gene Id	Gene	Z-Score
AF000139	cytochrome P450, family 27, subfamily b, polypeptide 1(Cyp27b1)	3.142163
AF016183	vomer nasal 2 receptor, pseudogene 45(Vom2r-ps45)	2.284991
AF026554	solute carrier family 5 member 6(Slc5a6)	1.552609
AF030243	interleukin 3 receptor subunit alpha(Il3ra)	1.890042
AF041374	phosphatidylinositol binding clathrin assembly protein(Picalm)	2.019124
AF053989	vomer nasal 2 receptor 44(Vom2r44)	1.534172
AF059678	replication factor C subunit 1(Rfc1)	1.961506
AF063103	adhesion G protein-coupled receptor L3(Adgrl3)	1.510015
AF063890	protein tyrosine kinase 2 beta(Ptk2b)	2.392998
AF065161	cytokine inducible SH2-containing protein(Cish)	2.074343
AF102262	beta-1,4-galactosyltransferase 1(B4galt1)	1.819501
AF106657	ubiquitin specific peptidase 15(Usp15)	2.061666
AF115768	defensin alpha 24(Defa24)	2.430658
AF121265	catenin beta 1(Ctnnb1)	1.995608
AF121893	single stranded DNA binding protein 3(Ssbp3)	1.660423
AF145050	eukaryotic translation elongation factor 1 delta(Eef1d)	1.902054
AF146738	centrosomal protein 19(Cep19)	1.815362
AF155196	No data	1.575313
AF169390	phosphodiesterase 6H(Pde6h)	1.774068
AF169636	leukocyte immunoglobulin-like receptor, subfamily B (with TM and ITIM domains), member 3-like(Lilrb3l)	3.098234
AF173834	calpain 3(Capn3)	1.680331
AF176023	PR/SET domain 4(Prdm4)	2.242755
AF178689	carbohydrate sulfotransferase 3(Chst3)	1.70415
AF187323	cathepsin Q(Ctsq)	2.106614
AF190256	phosphate cytidylyltransferase 1, choline, beta(Pcyt1b)	2.363304
AF201901	interferon gamma receptor 1(Ifngr1)	1.542342
AF208125	acyl-CoA synthetase bubblegum family member 1(Acsbg1)	2.403616
AF214647	N-acylsphingosine amidohydrolase 1(Asah1)	1.539499
AF218575	nibrin(Nbn)	1.875441
AF228043	nuclear receptor coactivator 6(Ncoa6)	1.721794
AF228917	zinc finger, DHHC-type containing 2(Zdhhc2)	1.609594
AF237778	calcium/calmodulin-dependent protein kinase II alpha(Camk2a)	1.638852
AF273025	solute carrier family 38, member 3(Slc38a3)	2.373408
AF276940	ectonucleoside triphosphate diphosphohydrolase 2(Entpd2)	2.0331
AF281304	potassium channel, two pore domain subfamily K, member 6(Kcnk6)	2.029054
AF288611	RUN domain containing 3A(Rundc3a)	2.840557
AF303035	PARP1 binding protein(Parpbp)	2.933101
AF308818	KH-type splicing regulatory protein(Khsrp)	1.694262
AF311055	thioredoxin 1(Txn1)	2.848762
AF333325	HPS1, biogenesis of lysosomal organelles complex 3 subunit 1(Hps1)	1.833169
AF333986	oxidation resistance 1(Oxr1)	2.393664
AF336113	actin-binding Rho activating protein(Abra)	2.216764
AF345444	potassium voltage-gated channel interacting protein 4(Kcnip4)	2.743564
AF368269	cytochrome P450, family 2, subfamily t, polypeptide 1(Cyp2t1)	1.620044
AF393750	BPI fold containing family A, member 1(Bpifa1)	2.365618
AF398465	dihydropyrimidinase-like 3(Dpysl3)	1.872371
AF419333	gamma-aminobutyric acid type A receptor theta subunit(Gabrq)	1.792286
AI059116	No data	1.626247
AI102932	No data	1.930485

### Appendix B. List of Genes Down-Regulated by PE Effect

Gene Id	Gene	Z-Score
AA944170	S/D	-1.506199
AA944489	No data	-1.530233
AA996993	No data	-2.983268
AB011529	cadherin, EGF LAG seven-pass G-type receptor 2(Celsr2)	-1.74635
AB011679	tubulin, beta 5 class I(Tubb5)	-2.325114
AB020504	No data	-2.211124
AB020757	chymotrypsin-like(Ctrl)	-2.059928
AB025017	No data	-2.29894
AB033418	No data	-2.907947
AB047540	isocitrate dehydrogenase 3 (NAD+) beta(Idh3B)	-1.980831
AB067445	integrin alpha 2(Itga2)	-1.977614
AF000944	general transcription factor IIA, 2(Gtf2a2)	-2.614055
AF006664	NK2 homeobox 5(Nkx2-5)	-1.571779
AF012714	multiple inositol-polyphosphate phosphatase 1(Minpp1)	-1.517925
AF015953	aryl hydrocarbon receptor nuclear translocator-like(Arntl)	-1.67005
AF016387	retinoid X receptor gamma(Rxrg)	-1.847981
AF021936	CDC42 binding protein kinase beta(Cdc42bpb)	-2.024961
AF026505	sorbin and SH3 domain containing 2(Sorbs2)	-1.84203
AF032120	GIPC PDZ domain containing family, member 1(Gipc1)	-1.832343
AF037071	nitric oxide synthase 1 adaptor protein(Nos1ap)	-2.242322
AF039584	CD55 molecule, decay accelerating factor for complement(Cd55)	-1.707524
AF053093	No data	-1.976489
AF053097	No data	-1.603483
AF084544	versican(Vcan)	-1.711944
AF092090	polyamine modulated factor 1 binding protein 1(Pmfbp1)	-1.629489
AF123651	spermatogenesis associated 2(Spata2)	-1.791841
AF151710	No data	-1.874231
AF170284	gap junction protein, beta 6(Gjb6)	-2.501274
AF193757	N-terminal EF-hand calcium binding protein 2(Necab2)	-1.515331
AF200359	UDP-glucose glycoprotein glucosyltransferase 1(Uggt1)	-2.250208
AF243515	BCL2/adenovirus E1B interacting protein 3(Bnip3)	-1.627503
AF247450	hyperpolarization-activated cyclic nucleotide-gated potassium channel 1(Hcn1)	-1.51455
AF277901	zinc finger protein 483(Zfp483)	-1.798414
AF302047	CXADR-like membrane protein(Clmp)	-2.140061
AF304429	mitochondrial pyruvate carrier 1(Mpc1)	-2.257792
AF307852	ARP3 actin related protein 3 homolog(Actr3)	-1.95466
AF323615	phospholipase C, epsilon 1(Plce1)	-4.175461
AF329856	phosphodiesterase 1C(Pde1c)	-1.504374
AF347935	interleukin 11(Ill1)	-1.674463
AF361476	Cbp/p300-interacting transactivator, with Glu/Asp-rich carboxy-terminal domain, 2(Cited2)	-1.710103

Gene Id	Gene	Z-Score
AF367467	selenoprotein S(Selenos)	-2.382484
AF379608	doublesex and mab-3 related transcription factor 1(Dmrt1)	-1.683129
AF400662	calcium voltage-gated channel auxiliary subunit alpha2delta 1(Cacna2d1)	-1.543195
AF537333	aurora kinase A(Aurka)	-1.661243
