## Sequencing of the entire mitochondrial genome by using NGS

The methodology captures sequencing information during replication of the target DNA [1,2]. The template was closed, single-stranded circular DNA created by ligating hairpin adaptors to both ends of the target double-stranded DNA. During the sequencing process, the template diffused into a sequencing unit that contains a single polymerase of a smallest volume. Upon addition of four fluorescent-labeled nucleotides that generate distinct spectra, the polymerase within each unit incorporated the nucleotides and fluorescent signals were emitted. The signals were recorded using a camera in real-time. As the replication processes of the target DNA continued, both strands of the target DNA could be sequenced multiple times.

After the system had generated the raw sequence data, a circular consensus sequence read was performed using PacBio's instrument control and SMRT Analysis software (<http://www.pacificbiosciences.com>). The read quality was checked using a Perl script ([http://david.abcc.ncifcrf.gov/manuscripts/pacbio\\_qc](http://david.abcc.ncifcrf.gov/manuscripts/pacbio_qc)) to produce a summary read-QC-parameter report. High-quality circular consensus sequence reads were aligned to the standard revised Cambridge Reference Sequence (NC\_012920.1, *Homo sapiens* mitochondrion complete genome), and variants were called and annotated with dbSNP IDs (<http://www.ncbi.nlm.nih.gov/SNP/>) by using SMRT Analysis software. The definition of the variants was the positions with nucleotide different from that in the reference sequence. Variants were defined as novel if they were not present in the MitoMAP database (updated March 19, 2018). The effects of nonsynonymous variants on protein function were predicted using the scale-invariant feature transform algorithm.

## N-acetyltransferase 2 (NAT2) genotype determination

NAT2 genotype was determined from genomic DNA by using direct sequencing in 34 patients with and 38 patients without DILI. Of 24 polymorphic sites of NAT2 gene, four lead to amino acid changes: 191G>A (R64Q), 341T>C (I114T), 590G>A (R197Q) and 857G>A (G286E). Presence of two of these variant alleles, one variant allele plus one common allele, and two common alleles in a patient was defined as slow, intermediate, and rapid acetylator genotypes, respectively [3,4].
