Abstract: Aromatic plants, also known as herbs and spices, have been used since antiquity as folk medicine and as preservatives in foods. The best known aromatic plants, such as oregano, rosemary, sage, anise, basil, *etc.*, originate from the Mediterranean area. They contain many biologically active compounds, mainly polyphenolics, which have been found to possess antimicrobial, antioxidant, antiparasitic, antiprotozoal, antifungal, and anti-inflammatory properties. Currently, the demand for these plants and their derivatives has increased because they are natural, eco-friendly and generally recognized as safe products. Therefore, aromatic plants and their extracts have the potential to become new generation substances for human and animal nutrition and health. The purpose of this review is to provide an overview of the literature surrounding the *in vivo* and *in vitro* use of aromatic plants.

Keywords: aromatic plants; bioactive compounds; polyphenolics

1. Introduction

The growing interest of consumers in substances of natural origin in addition to the increasing concern surrounding potentially harmful synthetic additives has resulted in the use of aromatic plants, their extracts and essential oils, as functional ingredients in the pharmaceutical, food and feed industries [1]. Such industries are currently looking for efficacious, safe and cost effective substances

with clearly defined modes of action and proven benefits. Plant derived components have considerable potential to fulfill such demands. Although there is still a lack of knowledge, especially regarding the consistency of *in vivo* trial results and mechanisms of action of various components within the aromatic plants [2], they could be applied as new generation compounds for human and animal health and nutrition. It is also important to take into consideration that improved animal health can translate to improved food safety and quality, which benefits the consumer.

2. Aromatic Plants

Aromatic plants, also known as herbs and spices, have been used in the Middle East since approximately 5000 BC for their preservative and medicinal properties, in addition to enhancing the aroma and flavor of foods [3–5]. Their use continues undiminished today and according to the World Health Organization (WHO) nearly 80% of the planet's population, especially in developing countries still depends on plant produced medicines for their healthcare [6,7]. Additionally, feed additives derived from plants, also called phytochemicals or phytobiotics or botanicals, can be included in animals' diets to improve their productivity and the properties of the resulting feed and animal products [8]. Among these natural additives, aromatic plants, their extracts and their essential oils have been examined due to their advantages over the antibiotics as growth promoters. They are residue free and generally recognized as safe (GRAS) [8–10].

Currently, there is an increasing interest in using herbs and spices in animal nutrition, in order to replace the use of antibiotics and ionophore anticoccidials, especially after the ban of antibiotic feed additives within the European Union countries in 2006 and discussions to restrict their use outside Europe [11,12].

Many herbs and spices can be found worldwide, with many originating from the Mediterranean area, either in the wild or cultivated, such as rosemary, oregano, sage, thymus, peppermint and garlic [13–16]. They contain chemical substances such as polyphenols, quinines, flavonols/flavonoids, alkaloids, polypeptides or their oxygen-substituted derivatives [17–19]. Some of these substances can act synergistically, so their bioactivity is enhanced [20]. Some bioactive compounds show therapeutic value, such as antioxidant and antiseptic activities [4,21]. Thus, they may reduce the risk of cancer or cardiovascular diseases [22,23] and may find application as treatments in curing or managing a wide range of ailments such as respiratory diseases and stomach or inflammatory disorders [16]. Generally, the bioactive components in the aromatic plants possess the ability to protect the body from damage caused by free radicals induced oxidative stress by quenching singlet oxygen and inducing cytochrome or other enzymes [4,24]. Moreover, herbs and spices can inhibit oxidative rancidity and delay the development of off-flavor in some products [25,26]. They also contain antimicrobial compounds which contribute to the retardation of microbial growth on foods and especially snack foods and meat products [2,4,27].

3. Essential Oils

Aromatic plants contain odorous, volatile, hydrophobic and highly concentrated compounds called essential oils (or volatile or ethereal oils). These are obtained from various parts of the plant such as flowers, buds, seeds, leaves, twigs, bark, wood, fruits and roots [9,18]. The essential oils are complex

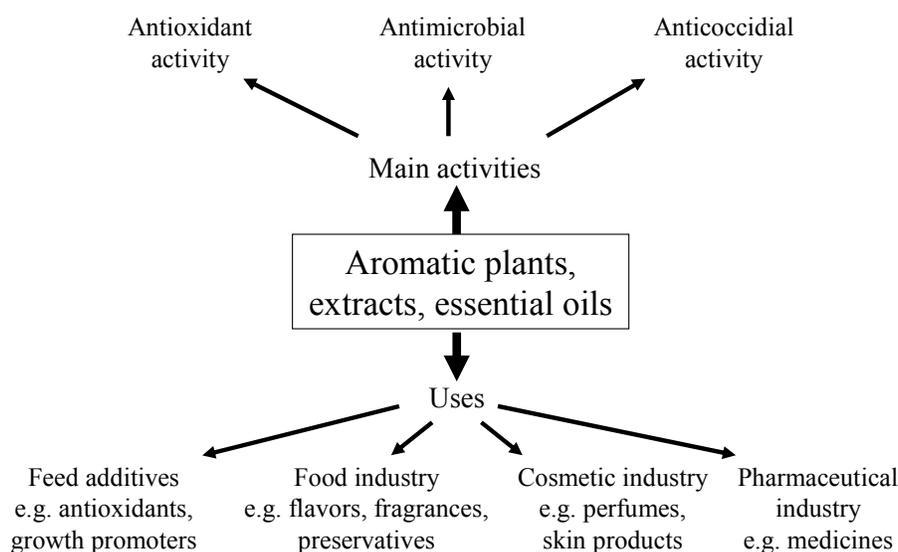

mixtures of secondary metabolites consisting of low-boiling-point phenylpropenes and terpenes [11]. The most important families from the point of essential oils are: *Asteraceae* or *Compositae*, *Lamiaceae* or *Labiatae* and *Apiaceae* or *Umbelliferae* [28].

Detailed compositional analysis of volatile compounds of the oils can be obtained by gas chromatography and mass spectrometry [9]. It was found that there are valuable mixtures of mainly terpenoids like linalool, geraniol, borneol, menthol, thujanol, citronnillol, α -terpineol and a variety of low molecular weight aliphatic hydrocarbons like phenols (thymol, carvacrol, eugenol, gaiacol) and aromatic aldehydes (cinnamaldehyde, cuminal and phellandral) [29].

The oils are usually extracted by steam distillation, while currently the use of supercritical carbon dioxide extraction has become increasingly popular [30]. Depending on type and concentration, essential oils exhibit cytotoxic effects on living cells, although non-genotoxic. The cytotoxic activity of essential oils is mostly due to the presence of phenols, aldehydes and alcohols [1]. Such cytotoxic activity is of great interest for applications against some human or animal pathogens and parasites, as well as for the preservation of agricultural and marine products [29]. It has been known for centuries that aromatic plants—mainly their essential oils or components—can act *versus* a large variety of organisms including bacteria, viruses, fungi, protozoa, parasites and insects [31–35]. Moreover, the essential oils can exhibit hypolipidemic [36], antioxidant [37], digestive stimulant [38], and antitoxigenic [39] activities and can also contribute in odor and ammonia control [10].

There are more than 3000 plants used for their essential oils of which about 300 are used commercially as flavors and fragrances [40]. As shown in Figure 1, the food industry uses the oils in soft drinks, food confectionary, *etc.*, and the cosmetic industry uses them in perfumes, skin and hair care products, aromatherapy, *etc.*, while the pharmaceutical industry utilizes them for their functional properties [30].

Figure 1. Activities and uses of aromatic plants.

4. Modes of Action

4.1. Antimicrobial Activity

As already mentioned the antimicrobial properties of the aromatic plants are partially attributed to their essential oils [41,42]. It is suggested that the hydrophobicity of the essential oils and their components is an important characteristic that enables the essential oils to accumulate in the lipid bilayer of the bacterial cell membrane and mitochondria, disturbing the cell structures and rendering them more permeable [43,44].

Moreover, the antimicrobial mechanism of some essential oils is the disruption of cell homeostasis leading to growth inhibition and cell death [45,46]. Nevertheless, it has been proposed that the chemical structure, such as the presence of the functional hydroxyl (–OH) group and the aromaticity are also responsible for the antibacterial activity [2,47,48].

The antimicrobial activity of the essential oils has been examined in studies against Gram-negative bacteria, demonstrating high antimicrobial capacity [49,50]. Clinical studies using the essential oils are scarce; they have been tested mainly topically on skin and mucous membranes [51]. Additionally, there is little information as regards safety in relation to the oral administration of essential oils [43]. Currently, essential oils represent a source of natural antimicrobial substances, which may be used in the food industry as biopreservatives to prevent food spoilage and to increase the shelf life of products. Furthermore, the essential oils could reduce side effects caused by the use of chemical preservatives [50].

It is generally accepted that phenolic compounds—having the hydroxyl group attached to a phenyl ring—have the greatest antimicrobial activity among the secondary metabolites found in essential oils [52,53]. Such examples are the monoterpenes carvacrol and thymol and the phenylpropene eugenol [54]. In addition, non-phenolic secondary metabolites found in essential oils have a variable antimicrobial capacity. Some researchers [52] reported that the antimicrobial activity of the monoterpenes *p*-cymene and γ -terpinene seems to be limited, compared with the phenolic monoterpenes, while others [55] reported that cinnamaldehyde, a non-phenolic phenylpropene exhibits strong antimicrobial activity.

The chemical composition of the essential oils can be influenced by the plant's natural origin, environmental and genetic factors, species and subspecies, geographical location, season of collection, plant part used and method of isolation [9,56].

Some aromatic plants and their extracts have been reported to stimulate the growth of certain bacteria, *i.e.*, to have a prebiotic-type effect [11]. Prebiotics are known for their ability to increase the endogenous intestinal populations of *Lactobacillus* and *Bifidobacterium*, resulting in beneficial health effects [42,57]. Generally, there are very few *in vivo* studies of the prebiotic effects of aromatic plants. However, they have been used in ruminants to manipulate rumen metabolism [11,54].

4.2. Antioxidant Activity

Aromatic plants and their essential oils are good sources of natural antioxidants, such as phenolic compounds, *e.g.*, eugenol, thymol, carvacrol [58,59]. Polyphenols generally occur as glycosides, although the bioactivity is attributed to aglycon structures and mainly to catechol in aglycons [60]. It is

considered that the antioxidant activity of these compounds is due to their high redox properties and chemical structure, which can be responsible for neutralizing free radicals, chelating transitional metals and quenching singlet and triplet oxygen by delocalization or decomposing peroxides [61–63]. The above properties are linked to the beneficial health functionality of the phenolic antioxidants because they contribute to the delay of many oxidative-stress related diseases, such as cardiovascular diseases, cancer, diabetes and Alzheimer's [64,65]. Moreover, plant phenols exhibit *in vitro* antioxidant activity, inhibiting lipid peroxidation by acting as chain-breaking peroxy-radical scavengers [66,67]. Therefore, they can play a protective role for highly unsaturated lipids in feed against oxidative damage [24,67], partly substituting the use of α -tocopheryl acetate or preservatives. Lipid oxidation in food products is considered as one of the main factors limiting product quality and acceptability, because of the production of reacting oxygen species (ROS) and off-flavors from polyunsaturated fatty acids [67,68].

Essential oils may also affect lipid metabolism in animal tissues by showing beneficial effects on the antioxidative enzymes (superoxide-dismutase and glutathione peroxidase) activity, as well as on polyunsaturated fatty acid composition [69]. Consequently, flavonoids are important substances in nutrition, although they are generally considered as non-nutrients [70].

Flavonoids may also act as pro-oxidants, especially those compounds that possess multiple hydroxyl groups [67,71]. After penetrating the inner cells membrane, flavonoids can be oxidized by ROS converting into pro-oxidants, which are able to oxidize lipids, proteins and DNA [19,29]. This mechanism may lead to late apoptosis or necrosis of damaged cells, thus playing a “protective” role by eliminating potential mutants [29].

5. *In vivo* Use of Aromatic Plants

Apart from *in vitro* experiments examining the biological activities of herbs and spices, many *in vivo* experiments have examined their beneficial impact as dietary supplements in nutrition. A summary of these results is presented in Table 1.

Table 1. Use of aromatic plants in animal nutrition.

Aromatic plant	Addition	Effect	References
Chickens broilers			
Oregano	Essential oil	No effect on performance	[72]
		Improved performance	[73]
		Anticoccidial effect	[74]
Oregano	Dried	Improved antioxidant capacity of products	[72,75,76]
		Improved performance	[77]
		Anticoccidial effect	[78]
		Improved antioxidant capacity of products	[77]
Anise	Essential oil	Improved performance	[79]
Anise	Seeds	Improved performance	[80]
Cinnamon	Extracts	Improved performance	[81]
Cinnamon	Essential oil	Improved performance	[82]
Rosemary	Extracts	Improved antioxidant capacity of products	[83]

Table 1. Cont.

<i>Aromatic plant</i>	Addition	Effect	References
Sage	Extracts	Improved antioxidant capacity of products	[83]
<i>Artemisia annua</i>	Dried leaves	Anticoccidial effect	[84]
<i>Sophora flavescens</i>	Extracts	Anticoccidial effect	[85]
<i>Sideritis scardica</i>	Dried	Anticoccidial effect	[86]
Blend	Essential oils	Anticoccidial effect	[87]
Blend	Essential oils	Anticoccidial effect	[88]
Blend	Extracts	Anticoccidial effect	[89]
Laying hens			
Mixture	Essential oils	Improved performance	[90]
Saffron	Dried	Improved antioxidant capacity of products	[91]
Oregano	Dried	Improved antioxidant capacity of products	[91]
Rosemary	Dried	Improved antioxidant capacity of products	[91]
Turkeys			
Oregano	Essential oil	No effect on performance	[92]
Oregano	Dried leaves	Improved feed conversion	[93]
Garlic	Dried	Improved performance	[94]
Laying quail			
Oregano	Dried plant	No effect on performance	[95]
Anise	Seeds	No effect on performance	[96]
Rabbits			
Oregano	Essential oil	No effect on performance	[97,98]
		Improved antioxidant capacity of products	[97,98]
		Improved health and carcass composition	[99]
		Inhibition of microbial growth	[98]
Oregano	Dried	Improved performance	[100]
Sage	Extracts	Improved health and carcass composition	[99]
Ruminants			
Various plants	Essential oils	Improved feed utilization	[44]
		Inhibition of ruminal methanogenesis	[44,101,102]

5.1. The Use of Aromatic Plants in Poultry Nutrition

5.1.1. The Use of Aromatic Plants as Performance Enhancers in Poultry Nutrition

Dietary oregano oil (50 and 100 mg/kg of feed) had no effect on performance of chickens [72]. Furthermore, dietary oregano oil (100 and 200 mg/kg) did not improve the performance of turkeys [92]. Nevertheless, dehydrated oregano plants (5 g/kg) exerted a growth promoting effect (better body weight gain and feed conversion ratio) when incorporated in chicken diets [77]. Dried oregano leaves (1.25, 2.5, and 3.75 g/kg) improved feed conversion ratio in early maturing female turkeys [93]. In addition, the dietary inclusion of dried oregano (10 or 20 g/kg diet) had no effect on the performance parameters of laying quail [95]. Furthermore, Basset [73] reported that oregano

essential oil improved the performance of chickens when supplemented through drinking water at 150 or 300 mg/L. These inconsistent results might be attributed to differences in the environmental conditions and/or the composition of the oregano supplement [77]. Due to the fact that the essential oil has much higher content of active substances, it is usually added in much lower percentages in the feed compared to dried plants. The major constituents of oregano are carvacrol, thymol, γ -terpinene and *p*-cymene, ranging between 802 and 984 mg/kg of the total plant [103,104].

In addition, anise (*Pimpinella anisum*) essential oil dietary supplementation at 400 mg/kg diet in broilers, resulted in significant better body weight gain and feed conversion ratio [79]. Similar results were reported by Soltan *et al.* [80] when broilers were fed anise seeds at 0.5–0.75 g/kg diet. Christaki *et al.* [96] found that anise seeds (10 or 20 g/kg diet) had no effect on the performance of the laying Japanese quail. Anise contains a number of bioactive compounds, anethole (main compound), pseudoisoeugenol, coumarins, scopoletin, umbelliferon, estrols, terpene hydrocarbons, polyenes and polyactylenes [105]. The use of powdered garlic (*Allium sativum*) as a feed additive (0.5%) in broiler chickens improved their performance [94]. The main bioactive compound of garlic is allicin, which exhibits remarkable antimicrobial activity [106]. Furthermore, the dietary addition of cinnamon extracts [81] or cinnamon essential oil [82] improved the performance of broilers compared with control groups. The findings of Bozkurt *et al.* [90] in laying hens showed that the essential oil mixture of six different plants (oregano, laurel, sage, myrtle, fennel and citrus) is an effective performance enhancer.

Still more work needs to be done in this area, since many other aromatic plants are possible candidates as performance enhancers in poultry nutrition.

5.1.2. The Use of Aromatic Plants as Anticoccidials in Poultry Nutrition

Coccidiosis, which is caused by protozoa of the genus *Eimeria*, is an intestinal parasitosis common in poultry. Coccidiosis is considered as one of the most severe health and welfare problems and is mainly controlled with the use of anticoccidial substances and on a lesser scale with vaccinations [89,107]. Certain dietary factors may diminish the negative effects of avian coccidiosis, including the use of herbs and spices [108]. Allen *et al.* [84] reported that dried leaves of *Artemisia annua* could protect chickens against caecal lesions caused by *Eimeria tenella* infection. Youn and Noh [85] found that *Sophora flavescens* extracts were more effective than *Artemisia annua* against *E. tenella* infection in chickens. Evans *et al.* [87] who investigated an essential oil blend from clove, thyme, peppermint and lemon, found a reduction of coccidia oocyst excretion in chicks fed the diets which contained the essential oil mixture. Aromatic plants of the *Labiatae* family and especially oregano exhibit coccidiostatic action against *E. tenella*, when the essential oil or ground leaves, flowers and stems of the plant are incorporated into chicken diets [74,78]. Another aromatic plant of the Mediterranean flora, belonging to the *Labiatae* family, Olympus tea (*Sideritis scardica*), exerted a coccidiostatic effect in broiler chickens challenged with 6×10^4 sporulated oocysts of *E. tenella*, although this effect was considerably lower than that exhibited by the commercially used anticoccidial lasalocid [86].

Analogous results were reported by Christaki *et al.* [88] in which a blend of herbal extracts from the plants *Agrimonia eupatoria*, *Echinacea angustifolia*, *Ribes nigrum* and *Cinchona succirubra*

were fed to chickens experimentally challenged with 6×10^4 sporulated oocysts of *E. tenella*. Also, Azcrewska-Wlosek and Swiarkiewicz [89] concluded that treatment with a herbal extract mixture containing *Allium sativum*, *Salvia officinalis*, *Echinacea purpurea*, *Thymus vulgaris* and *Origanum vulgare* partly alleviates the negative impact of *Eimeria* experimental infection (*E. acervulina*, *E. tenella*, *E. maxima* and *E. necatrix*) in broiler chickens.

These studies are important considering the need to find alternative solutions to chemical anticoccidials is of special urgency because European Union countries are planning to ban the use of chemical anticoccidials in livestock nutrition at the end of 2012 [109].

5.1.3. The Use of Aromatic Plants as Antioxidants in Poultry Nutrition

Some herbs of the *Labiatae* family have been extensively studied for their antioxidant activity. It has been shown that dietary supplementation with extracts of rosemary and sage [83] or oregano essential oil could improve the oxidative stability of raw and precooked broiler meat products during refrigerated storage [72,75] or frozen storage at -20°C for a period of up to 9 months [76]. Giannenas *et al.* [77] reported that the dietary combination of dehydrated oregano and α -tocopheryl acetate supplementation in broiler diets exhibited antioxidant activity higher than that presented by α -tocopheryl acetate supplementation alone. As regards the effect of aromatic plants on egg yolk, it was reported [91] that saffron, oregano or rosemary had an antioxidative effect on hen egg yolks but this was not as strong as α -tocopheryl acetate.

For the above *in vivo* trials, particularly important is the improved oxidative stability of the poultry meat products or egg yolk, observed may have resulted from the action of antioxidant compounds such as the phenolic isomers thymol and carvacrol found in the extracts and essential oils from the aromatic plants [58,67].

5.2. The Use of Aromatic Plants in Rabbit Nutrition

There are a limited number of *in vivo* trials dealing with the use of aromatic plants in rabbit nutrition. According to Ayala [100] dietary supplementation with dried oregano improved rabbit performance, while Pogany-Simonova *et al.* [99] reported that oregano and sage extracts improved rabbit health and carcass amino acid composition. Other researchers [97,98] found that oregano essential oil had no effect on performance parameters of rabbits and significantly increased the antioxidative capacity of raw and thermally treated carcasses during refrigerated storage. Additionally, dietary oregano essential oil was effective in inhibiting microbial growth on rabbit carcasses during refrigerated storage [98]. These carcasses also exhibited noticeably less slime and off-odors than the controls. It is possible that oregano essential oil components entered the circulatory system, were distributed and retained in tissues and thus are responsible for the exhibited antioxidant and antimicrobial activities. The bioavailability of any of these components cannot be directly demonstrated, since an analytical method capable of identifying and quantifying them at trace levels in tissues has not yet been developed [98].

5.3. The Use of Aromatic Plants in Ruminant Nutrition

Evidence for *in vivo* antimicrobial activity of aromatic plant essential oils has not yet been confirmed in ruminants, although oils have been used to manipulate ruminal metabolism in order to improve feed efficiency and animal productivity [11,54]. Nevertheless, results from *in vitro* batch culture studies provide evidence that essential oils or their components have the potential to improve nitrogen and/or energy utilization in ruminants by altering microbial populations [44]. These responses are only observed with high doses of essential oils, which also can inhibit the process of ruminal fermentation causing a decline in total volatile fatty acid production, although rumen microbial populations adapt after long term exposure to these substances [44,54]. Also, the fact that some aromatic plants derived substances show a strong bactericidal activity against pathogenic bacteria such as *Escherichia coli* and *Salmonella* spp. [110], has prompted some researchers to examine their potential to reduce ruminal methanogenesis [44,101,102], limiting the release of this important greenhouse gas into the atmosphere.

In vivo research using novel aromatic plants in rumen nutrition has the potential to benefit animal production and health, as well as the environment.

6. Conclusions

Aromatic plants, their extracts and essential oils contain a variety of functional bioactive compounds, which have possible applications in the food, feed, pharmaceutical and cosmetic industries. However, aromatic plants and their extracts should be standardized and properly controlled in their extraction and composition, in order for the study of these plants to yield meaningful data. *In vitro* studies using standardized extracts should be completed prior to *in vivo* experimental research, to confirm the efficacy of the extracts. In this way, viable alternative methods for enhancing performance or improving shelf-life of the animal products may be developed, satisfying the consumer's demands for natural, safe and high quality foods.
