## Full experimental details

**Pocillopora damicornis.** Samples of the coral *P. damicornis* were collected in Oman and were acclimated for more than one year in tanks at the Banyuls Oceanological Observatory. Corals were maintained in artificial seawater (ASW) prepared with reverse osmosis purified water and Reef Salt SeaChem salts. Salinity was adjusted to 36 g/L, pH = 8, and the temperature was set at 24 °C. All experiments were conducted with the same ASW.

**Preparation of Coral for Exposition to Solar Filters.** Coral pieces (1–1.5 cm) were cut from branch tips from the same mother colony. Each piece was attached to a fishing line, and the coral pieces were then suspended each on one ~5–6 cm plastic grid, making sure the lines had the appropriate length so that the coral pieces will stand in the middle of exposure beakers during the assay. Each suspended coral nubbin (five replicates) was clamped to grid above the aquarium of origin, thereby immersing the pieces. The suspended pieces were acclimatized for approximately 1 month before the assay to allow for full healing.

**Exposure Setup.** Beakers (250 mL) were filled with ASW (200 mL). BM ( $\geq$ 98.0%, Sigma-Aldrich) was dissolved in DMSO at concentrations of 400, 120, 20, and 2  $\mu$ g/mL. Each of these solutions (500  $\mu$ L) was added into separate beakers, resulting in final concentrations of 1000, 300, 50, and 5  $\mu$ g/L. DMSO (500  $\mu$ L) was used as a negative control, and the DMSO concentration was 0.25% v/v in all beakers. The suspended coral pieces were dipped into the beakers, with the grid positioning the pieces halfway into the water. Gentle bubbling in the beakers was maintained using aquarium air pumps equipped with a Teflon tubing with Pasteur pipettes tips. Homogeneous lighting was set to 250  $\mu$ mol/m<sup>2</sup>/s, with a cycle of 10 h of day and 14 h of night. The corals were transferred every 24 h to a new beaker prepared in the same way. The total exposure lasted for 7 days. Pictures were taken every 24 h to monitor coral polyps. Coral exposure at 1000  $\mu$ g/L BM was repeated in a separate experiment to confirm the result.

**Extraction.** After 7 days, the coral pieces were collected and the fishing lines were removed with a scalpel. Each coral piece was placed into a 20 mL test tube, covered with MeOH/acetonitrile 1/1, and sonicated for 20 min. Once the polyps were dissolved, the solvent was evaporated and the dry samples were kept at –80 °C until analysis. All solvents used for extraction and profiling were LC-MS gradient grade (Biosolve, Dieuze, France).

**UHPLC-HRMS Profiling.** High-resolution MS/MS analyses were conducted with a Thermo UHPLC-HRMS system. Analyses were performed in the electrospray positive ionization mode in the range of 133.4–2000 Da in centroid mode. The mass detector was an Orbitrap MS/MS FT Q-Exactive focus mass spectrometer. The analyses were conducted in FullMS data dependent MS<sup>2</sup> mode. In FullMS, the resolution was set to 70000, and the AGC target was  $3 \times 10^6$ . InMS<sup>2</sup>, the resolution was 17500, AGC target  $10^5$ , isolation window 0.4 Da, and stepped normalized collision energy 15/30/45 was used, with 6 s dynamic exclusion. The lock mass option was set for ion at m/z 144.98215, corresponding to Cu(CH<sub>3</sub>CN)<sup>2+</sup>. The UHPLC column was a Phenomenex Luna Omega polar C-18 150 mm × 2.1 mm, 1.6  $\mu$ m. The column temperature was set to 42 °C, and the flow rate was 0.5 mL·min<sup>-1</sup>. The solvent system was a mixture of water (solution A) with increasing proportions of acetonitrile (solution B), both solvents modified with 0.1% formic acid. The gradient was as follows: 2%

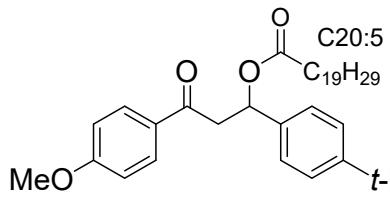

B 3 min before injection, then from 1 to 13 min, a shark fin gradient increase of B up to 100% (curve 2), followed by 100% B for 5 min. The flow was diverted (not injected into the mass spectrometer) before injection, up to 1 min after injection. The coral extracts were dissolved in MeOH (1 mg/mL) by sonication, and 2  $\mu$ L was injected onto the column. Standard of synthetic palmitic acid dihydroBM ester (**7**) in acetonitrile (0.1  $\mu$ g/mL, 1  $\mu$ L injected) was analyzed with the same method.

**Metabolomic Analyses.** Profiles were analyzed with Compound Discoverer (CD) 2.1 (ThermoFisher, Villebon, France). Coral exposed to DMSO was used as the reference metabolome, and blank injections were used to remove irrelevant ion peaks (ion peak is considered only if the signal is at least 5 times more intense than in the blank). An untargeted metabolomic workflow was used. This workflow finds and identifies the differences between samples and performs retention time alignment, unknown compound detection, and compound grouping across all samples. The workflow predicts elemental compositions for all compounds, fills gaps across all samples, hides chemical background (using Blank samples), identifies compounds using mzCloud (ddMS<sup>2</sup>) and ChemSpider (formula or exact mass), performs similarity searches for all compounds with ddMS2 data using mzCloud, and calculates a differential analysis (t-test or ANOVA) and determines p values, adjusted p values, ratios, and fold change. The retention time window was set to 2–17 min. The maximum shift for alignment was 0.1 min, the maximum mass tolerance was 2 ppm and the minimum peak intensity was  $2 \times 10^6$ . Statistical analyses (Principal Component Analysis [PCA], volcano plots) were performed with CD using centered and scaled data.

**Predicted toxicity of BM derivatives compared to BM.** The prediction of BM derivatives toxicity in aquatic organisms was carried out using an ecological structure-activity relationships (ECOSAR) predictive model. This model estimates acute and chronic toxicity concentrations for aquatic organisms by analyzing chemical structure similarity, using data reported to USEPA. To accomplish this task, ECOSAR V 2.2 was utilized in the study, which is distributed by the EPA (<https://www.epa.gov/tsca-screening-tools/ecological-structure-activity-relationships-ecosar-predictive-model>). For acute toxicity, LC<sub>50</sub> values on green algae (EC<sub>50</sub> at 96 h), daphnids (LC<sub>50</sub> at 48 h), and fish (LC<sub>50</sub> at 96 h) were considered. ECOSAR also generated predicted chronic toxicity information (Chronic Value, ChV) using the geometric mean of the predicted lowest observed effect concentration (LOEC) and the predicted no observed effect concentration (NOEC). Results for compounds **1**, **4**, **7**, **11** and **12** and reported in Table S1.

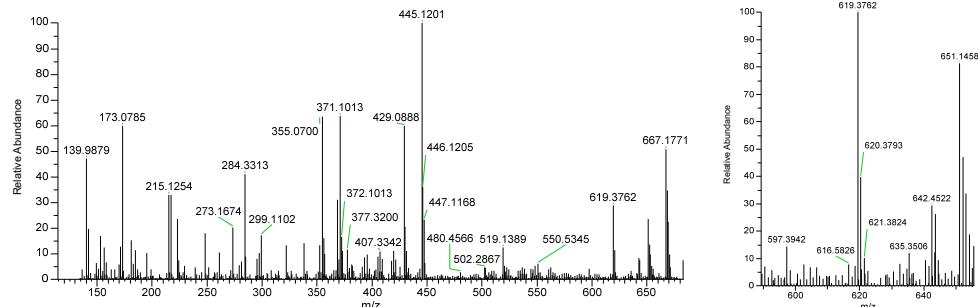

**Table S1.** ECOSAR v2.2 predicted toxicity of BM derivatives compared to BM (**1**)

Cmpd.	Acute (mg/L)			Chronic (mg/L)
