A: regression coefficient not applicable for synthesis, b: was included also because it was included in the synthesis of odds ratio

Table S3. Adjustments in models of each study

Study (Author, year)	Adjustments
Abiemo et al, 2013[1]	Age, gender, nationality, health center, education status, family income, smoking, PA, energy intake, waist circumference
Ahmad et al, 2020[2]	Age, treatment, energy intake, insulin resistance, BMI, HDL, LDL, hypertension, HbA1c, biochemical markers and inflammation markers
Andre et al, 2020[3]	Age, gender, education status, energy intake, sedentary life, smoking, overweight
Bantle et al, 2016[4]	Age, sex, race, field center, BMI, education, smoking, caloric intake, and tertiles of physical activity
Brunner et al, 2008[26]	Age, gender, nationality, smoking, PA, social economic status, dietary misreporting
Cabrera De Leon et al, 2011[6]	Age, sex, impaired fasting glucose, Canary Islands ancestry, metabolic syndrome, low HDL cholesterol, arterial hypertension, waist-to-height ratio >0.55, waist circumference > 94 or > 80 cm, insulin resistance, BMI ≥ 30 kg/m ² , family history of Type 2 diabetes mellitus, alcohol intake, sedentarism, adherence to Mediterranean diet, social class, and interaction terms between these variables.
Chen et al, 2018 [7]	Model 1 adjusted for age at baseline interview (years), sex, dialect group (Hokkien or Cantonese), year of baseline interview (1993–1995 or 1996–1998), and energy intake (kcal/day). Model 2 included the potential confounders in model 1 and additionally adjusted for body mass index, physical activity (no moderate or vigorous activity; 0.5–3.9 hours/week of moderate activity or 0.5–1.9 hours/ week of vigorous activity; or ≥4.0 hours/week of moderate activity or ≥2.0 hours/week of vigorous activity), education (no for- mal education, primary school, or secondary school or higher), smoking (never smoker, former smoker, current smoker of 1–12 cigarettes/day, or current smoker of ≥13 cigarettes/day), and self-reported history of physician-diagnosed hypertension. Analyses for the aMED, AHEI-2010, and DASH indices additionally adjusted for coffee consumption (cups/day), and analyses for the DASH, PDI, and hPDI indices additionally adjusted for alcohol consumption (none, light (<0.5 servings/ day), moderate (0.5–1.9 servings/day for men and 0.5–1.4 servings/day for women), moderate to heavy (2.0–3.4 servings/ day for men and 1.5–2.4 servings/day for women), or heavy (≥3.5 servings/day for men and ≥2.5 servings/day for women)).
De Koning et al, 2011[27]	Age, smoking, PA, BMI, family history, coffee consumption, energy intake
Esfandiar et al, 2022[9]	Age, sex, diabetes risk score, physical activity, smoking, dietary fiber, and total energy intake
Galbete et al, 2018[10]	Age, sex, smoking status, education, total energy (kcal/day), vitamin supplementation, body mass index (kg/m ²), waist circumference (cm), cycling, sports, prevalent hypertension (not in the analyses on cancer)
Glenn et al, 2023[11]	Model 1 adjustments include age (continuous), region (Northeast, South, Mid- west, West), smoking (never, past, current) and study arm (HRT, DM, CaD). Model 2 adjustments include model 1 adjustments plus self-identified race and ethnicity (White, African American, Hispanic, Asian), education (college or above, below college), marital status (presently married, other), hysterectomy history (yes, no), physical activity (continuous), alcohol intake (\$7 drinks/week, <7 drinks/week [excluded from aMED analysis, as alcohol intake is included in the score]), energy intake (continuous), hypertension status (yes, no), family history of diabetes (yes, no), HT use (never, past, current), cholesterol-lowering medication use (yes, no). Model 3 adjustments include model 2 adjustments plus BMI (continuous).
Hlaing- Hlaing et al, 2021[12]	Adjusted covariates were age; socioeconomic status (marital status, residence, education, occupation, and ability to manage income); lifestyle variables (smoking status, physical activity, taking prescribed and over-the-counter medicine) for all NCD outcomes. History of depression and/or anxiety at any previous survey(s) was included as a covariate
Hodge et al, 2021[13]	Age, sex, SEIFA, smoking status, drinking status, family history of diabetes and physical activity level at baseline, BMI, WHR, country of birth
InterAct Consortium et al (Romaguera et al), 2011 [14]	Gender, smoking, PA, energy intake, education status & model was stratified based on research center and was adjusted for gender, BMI, education level, physical activity, smoking and energy intake.
Jacobs et al, 2014[15]	age, adjusted for physical activity (h/week), smoking (current smoker, past smoker, never smoker), years of education (<12, 12, 13–15 and ≥16 years), total energy intake (kJ/day) and BMI (<22, 22 to <25, 25 to <30 and ≥30 kg/m ²). Models including men of all ethnicities combined were additionally adjusted for ethnicity (white, Japanese-American, Native Hawaiian and other ethnicity)

Koloverou et al, 2015[28]	Age, gender, family DM history, smoking, hypertension, hypercholesterolemia, education, PA, waist circumference
Martinez Gonzalez et al, 2008[29]	Age, gender, education years, BMI, family DM history , hypertension, PA, hours of sedentary life, smoking, energy intake
Mozzafarian et al, 2007[19]	model was adjusted for age, gender, smoking, time since MI to entry of study, treatment category, BMI, maximal capacity to exercise during stress testing (quintiles), presence of ischemia during stress testing, New York Heart Association heart failure symptoms, Canadian Cardiovascular Society angina symptoms, history of hypertension, prior MI before the incident that was for inclusion to the study, use of angiotensin converting enzyme inhibitors , use of b-blockers, use of diuretics, use of statins, cheese, wine and coffee consumption
O'Connor et al, 2020[20]	Age, gender, health center, energy intake, PA, smoking, clinical markers, social status, behavior, nationality, BMI
Ortega et al, 2013[21]	Multiple adjusted models included age, BMI and WC (as continuous variables), sex, educational level (university vs. lower than university education), civil status (married vs. others), hypertension, dyslipidemia, physical exercise (exercising at least once a week), smoking status (current vs. never/former) and a family history of diabetes in 1st-degree relatives.
Ramezan et al, 2019[22]	Model 1: conditional analysis matched on age, sex, and date of data collection and controlled for family history of diabetes, body mass index, educational level, smoking status, physical activity, and total energy intake. Model 2: multiple adjusted model, additionally adjusted for waist circumference, hypercholesterolaemia, and hypertension.
Rossi et al, 2013[23]	Age, gender, education status, BMI, PA, WHR, energy intake
Tison et al, 2022[24]	Crude model: unadjusted estimates. Model 1: adjustment for TEI and demographics of age, race, sex, region, income, and education. Model 2: further adjustment for lifestyle factors of smoking, physical activity, and alcohol.
Tobias et al, 2012[25]	Age, energy intake, BMI, nationality, smoking, PA, family history. 3 models: 1 st was adjusted for age and energy intake, 2 nd for number of births, age for the birth of first child, nationality, family history of DMT-2, use of contraceptives, phase of reproductive age (menopause stages), smoking, physical activity, and in the 3 rd BMI was added to adjustments

Table S5: Study Quality Assessment with Joanna Briggs Institute (JBI) Scale

Study (Author, year)	Were the two groups similar and recruited from the same population?	Were the exposures measured similarly to assign people to both exposed and unexposed groups?	Were confounding factors identified?	Were strategies to deal with confounding factors stated?	Were the groups/ participants free of the outcome at the start of the study (or at the moment of exposure)?	Were the outcomes measured in a valid and reliable way?	Was the follow up time reported and sufficient to be long enough for outcome to occur?	Was follow up complete and if not, were the reasons to loss to follow up described and explored?	Were strategies to address incomplete follow up utilized?	Was appropriate statistical analysis used?	Overall appraisal	Comments

BMI<25	3	0.94 (0.76 – 1.15)	0.15 – 5.84	0.0097 (0.00 – 1.10)	34%, (0.0 – 78.5) 0.22	
BMI≥25	3	0.86 (0.80 – 0.93)	0.73 – 1.02	0 (0.00 – 0.00)	0%, (0.0 – 84.7) 0.97	

BMI: Body mass index; CI: Confidence interval; HR: Hazard ratio; NA: Not applicable

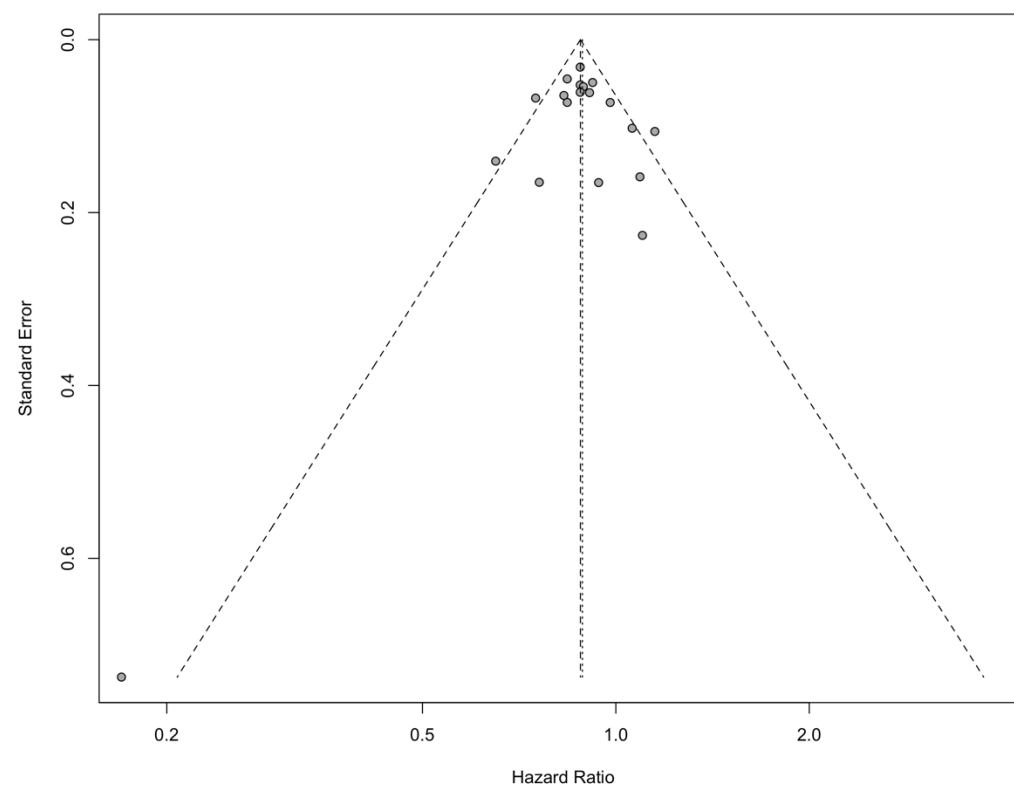

Figure S4. Funnel plot

Figure S5. GRADE Certainty of evidence

Question: High adherence to the MD compared to low adherence for type 2 diabetes mellitus prevention

Certainty assessment							№ of patients		Effect		Certainty	Importance
№ of studies	Study design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	high adherence to the MD	low adherence	Relative (95% CI)	Absolute (95% CI)		
Diabetes risk (HR)												
18	non-randomised studies	not serious	serious ^a	serious ^b	not serious	none	100 participants	100 participants	HR 0.89 (0.83 to 0.95) [Diabetes risk (HR)]	0 fewer per 1,000 (from 0 fewer to 0 fewer)	⊕⊕○○ Low	
							-	-		0 fewer per 1,000 (from 0 fewer to 0 fewer)		
Diabetes risk (OR)												
5	non-randomised studies	not serious	not serious	serious	not serious	none	100 participants	100 participants	OR 0.82 (0.72 to 0.93)	0 fewer per 1,000 (from 0 fewer to 0 fewer)	⊕⊕⊕○ Moderate	
							-	-		0 fewer per 1,000 (from 0 fewer to 0 fewer)		

CI: confidence interval; **HR:** hazard Ratio; **OR:** odds ratio

Explanations

a. No overlap of confidence intervals between studies. Also, the point estimates of the included studies were not similar

b. Not same populations and MD adherence tools
