

Supplementary Figure 1 A: Conidia of *M.acerina* artificially induced in a petridish, the size of the conidia is $(137.36\sim486.24\mu\text{m}) \times (4.35\sim16.46\mu\text{m})$ (n=100). B: The diseased spots of *P. notoginseng* leaves 4 days after inoculation with single conidia. C: Early lesions of round spot disease of *P. notoginseng*.

Supplementary Figure 2 A: The diseased spots 72h after the inoculation of *P. notoginseng* leaves were sprayed with 5×10^3 CFU/mL conidia suspension. B: the lesions magnified with an optical microscope. C: The inoculated *P. notoginseng* leaves were stained with fluorescent dye (Calcofluor white stain). A conidia can be seen on the lesion under the fluorescence microscope (Leica DM 2000). D: Conidia produced at the site of a diseased spot, bar=100 μ m.

Supplementary Figure 3 A: *Panax notoginseng* with serious incidence of round spot disease without shelter from rain. B: *P. notoginseng* cultivated in shelter from rain is growing well, and there is almost no occurrence of disease.

Supplementary Figure 4 Representative result amplification pattern generated in part of *Mycoentrospora acerina* samples. Lanes M = DL50 marker; lanes 1 to 32 = partial *M. acerina* isolates.

Supplementary table 1 *Mycocentrospora acerina* populations examined in the simple sequence repeat analysis.
