Abstract: To investigate the translation of a compound particle in a highly viscous, incompressible fluid, we carry out an analytic study on flow past a fixed spherical compound particle. The spherical object is considered to have a rigid kernel covered with a fluid coating. The fluid within the coating has a different viscosity from that of the surrounding fluid and is immiscible with the surrounding fluid. The inertia effect is negligible for flows both inside the coating and outside the object. Thus, flows are in the Stokes regime. Taking advantage of the symmetry properties, we reduce the problem in two dimensions and derive the explicit formulae of the stream function in the polar coordinates. The no-slip boundary condition for the rigid kernel and the no interfacial mass transfer and force equilibrium conditions at fluid interfaces are considered. Two extreme cases: the uniform flow past a sphere and the uniform flow past a fluid drop, are reviewed. Then, for the fluid coating the spherical object, we derive the stream functions and investigate the flow field by the contour plots of stream functions. Contours of stream functions show circulation within the fluid coating. Additionally, we compare the drag and the terminal velocity of the object with a rigid sphere or a fluid droplet. Moreover, the extended results regarding the analytical solution for a compound particle with a rigid kernel and multiple layers of fluid coating are reported.

Keywords: Stokes flow; stream function; axisymmetric flow; compound particle; fluid coating

1. Introduction

The flow around an object moving in highly viscous, incompressible fluid has been an interesting subject in fundamental studies and applications. The applications range widely from the determination of electron charges [1–3], physics aerosols [4], and medical applications [5], to biotechnological industries and engineering processes. From the very first study on the effects of viscosity pendulums [6], to a rigid body moving in an arbitrary flow [7], to fluid drops translating in another fluid [8], numerous works considering the motion of rigid and fluid objects in both bounded and unbounded domains have been reported. In the body frame, the translation of a particle in fluid is equivalent to the flow past a fixed obstacle. The problem of Stokes flow past a spherical object is an important one, owing to the manifold applications in science and engineering.

To analyze the flows, explicit and analytical solutions play a critical role. For example, an analytical solution is the starting point of the stability of a particle sediment. However, analytical solutions are rarely obtained for objects moving in flows, even in the Stokes regime. Uniform flow past a rigid sphere is first extensively studied [9], then the study of exact solutions is extended to the linear flow past an ellipsoid [10], and more work about other background flows past spheres or a spheroid [11]. Utilized with a singularity method, studies have been extended to linear and quadratic flow past a spheroid [12–15]. The exact solution of uniform flow past a fluid drop has also been reported [16,17].

Recently, compound multiphase particles have received much interest because of their significance in a variety of biomedical applications [18–23]. Johnson [19] studied the uniform Stokes flow
past a rigid sphere with a thin immiscible fluid film covering its surface using a perturbation scheme. In his work, the fluid-film profile is achieved by numerical calculations. Later, Johnson and his collaborators further studied bubbles and drops partially coated with thin films [24,25]. Gupta et al. [26] extended Johnson’s work [19] to micropolar fluid for the outer region [26]. Rushton and Davies [27] studied an encapsulated droplet, which is a spherical two-layer fluid object. However, they focused on the drag force only. In their paper, there is no report about parameters for the stream functions, which are keys to exploring the flow pattern. Also, it is important to notice that the boundary conditions at the interface inside the fluid drop are different from the boundary conditions between the rigid kernel and the fluid coating of the object studied in this paper. Li and Pozrikidis [28], and Blawzdziewicz et al. [29] investigated the effects of insoluble surfactants on the hydrodynamics and rheology of dilute emulsions in Stokes flow numerically. Most recently, Datta and Raturi [30] studied a swarm of spherical particles by modifying boundary conditions to account for the interaction effect. However, the flow with compound particles is not fully understood yet.

In this paper, we study the problem of a rigid spherical kernel, with a fluid coating, falling freely in a viscous dominated fluid. In the body frame (the moving frame), this is the problem for uniform flow past a fixed spherical object. Rigorous analytical solutions for stream functions are achieved by taking advantage of the axial symmetry properties. The hydrodynamic drag and terminal velocity are analyzed. From a rigid kernel with one layer of fluid coating, we extend the study to spherical particles with multiple-layer coating. Results from this study can shed light on the hydrodynamics of biomedical applications with similar obstacles. In those applications, the movement of particles is essential for drug delivery [31,32] and metastasis movements [33] of cancers. For example, magnetic beads coated with antibodies are used to isolate circulating tumor cells [34].

2. Formulation of Problem

Assume that a sphere with a rigid kernel and a fluid coating is embedded in unbounded, uniform fluid flow with constant velocity $U$, density $\rho$ and dynamic viscosity $\mu$. The rigid kernel

$$x^2 + y^2 + z^2 = a^2, \quad a \geq 0,$$

is covered by a layer of fluid coating. The fluid coating with thickness $d \geq 0$ occupies

$$a^2 \leq x^2 + y^2 + z^2 \leq R^2, \quad R = a + d.$$

Figure 1 schematically illustrates the setup of the problem.

![Figure 1](image-url)

Figure 1. Uniform flow past a rigid sphere with a fluid coating. The background uniform flow is $U = Ue_z$. The dark colored region indicates the rigid spherical kernel with radius $a$. The light colored region shows the fluid coating with thickness $d$. In total, the radius of the obstacle is $R = a + d$. 
If the thickness of the fluid layer, \( d \), is zero, this is reduced to the problem of uniform flow past a purely rigid sphere. If the radius of the rigid kernel, \( a \), is zero, the problem is indeed the flow past a fluid drop, as long as \( d > 0 \). The density and dynamic viscosity of the fluid within the layer of coating are \( \bar{\rho} \) and \( \bar{\mu} \), respectively. The fluid in the coating is assumed to be immiscible with the surrounding background fluid and the surface tension at the fluid interface is sufficiently strong to keep the obstacle spherical against any deformation.

Since both fluids are incompressible, the continuity equation is \( \nabla \cdot \mathbf{u} = 0 \), where \( \mathbf{u} \) is the flow velocity. In this paper, we assume that the inertial terms in the Navier–Stokes equations for both fluids can be neglected. Thus, the equations of motion are

\[
\mu \nabla^2 \mathbf{u} = \nabla p, \tag{3}
\]

where \( p \) denotes the fluid pressure. Similar governing equations apply to the fluid coating, but the viscosity of the fluid \( \bar{\mu} \) can be different from the viscosity \( \mu \) of the fluid in the unbounded domain. Later, subindices are also used to identify different fluids. The condition for (3) to hold is that \( Re = U R \rho / \mu \ll 1 \), where \( U \) is the magnitude of the uniform velocity \( \mathbf{U} = U \mathbf{e}_z \). For example, the Reynolds number is about \( 10^{-3} \sim 10^{-4} \) for the flow with \( \text{CO}_2/\text{HCO}_3^- \) past a \emph{Xenopus} oocyte \cite{32,35}.

The boundary conditions are no-slip boundary condition at the solid–fluid interface, and no-slip and no interfacial mass transfer condition (no penetration and continuity of tangential velocity) at the fluid interface. This forms a force equilibrium condition at the fluid–fluid interface. Also, \( \mathbf{u} \) is asymptotic to the basic uniform flow at large distances from the obstacle. These conditions are specified explicitly when we derive analytical solutions.

### 3. Analytical Solution for Uniform Flow past Spherical Objects

Before reporting the solution for the uniform flow past a general two-layer obstacle at Section 3.3, two extreme cases are reviewed. The case is the well-known result for a uniform flow past a fixed rigid sphere. The other one is the flow past a fluid drop, in which the viscosity is different from the background flow. The two fluids are immiscible. These simple cases are documented in the paper to make it self-contained when we compare the results between different problems. As we provide the results for these simple cases, it is also helpful to illustrate the derivation of the general multiple-layer obstacle.

#### 3.1. Uniform Flow past a Rigid Sphere

If the thickness \( d \) of the fluid coating is zero in Figure 1, this is the well-known uniform flow past a rigid sphere. With the axisymmetric property, the problem is reduced to two dimensions. In this situation, the stream function and velocity can be found in the literature. In spherical polar coordinates (\( \theta = 0 \) in the direction of \( \mathbf{U} \)) the stream function is \cite{16,17,36}

\[
\Psi(r,\theta) = U \frac{\sin^2 \theta}{2} \left( r^2 - \frac{3ar}{2} + \frac{a^3}{4r^3} \right). \tag{4}
\]

This result was obtained by Stokes \cite{6}. Inside the parentheses, the first term corresponds to the uniform background flow, and the second term is due to the doublet \cite{12}; together they represent an inviscid flow past a sphere. The third term representing the viscous correction is the Stokeslet.

The velocity components \( v_r \) and \( v_\theta \) in the polar coordinates are

\[
v_r = \frac{1}{r^2 \sin \theta} \frac{\partial \Psi}{\partial \theta} = U \cos \theta \left( 1 - \frac{3a}{2r} + \frac{a^3}{2r^3} \right), \tag{5}
\]

\[
v_\theta = -\frac{1}{r \sin \theta} \frac{\partial \Psi}{\partial r} = -U \sin \theta \left( 1 - \frac{3a}{4r} - \frac{a^3}{4r^3} \right). \tag{6}
\]

Figure 2 shows streamlines in the symmetry plane.
Figure 2. Streamlines in the symmetry plane for a uniform flow past a rigid sphere. The radius of the rigid sphere is $a = 1$.

From this figure, it is obvious that there are two stagnation points on two sides of the sphere [14,15]. The flow is separated by the stagnation lines attached to the stagnation points on the sphere.

According to the stream functions and velocity fields, the Stokes force $F$ exerted on a rigid stationary spherical particle immersed in the uniform Stokes flow field $U$ is

$$F = 6\pi \mu a U.$$  \hspace{1cm} (7)

By Newton's law, when the sphere reaches its terminal velocity $U$, the forces acting on the sphere are balanced. Thus, the magnitude of the terminal velocity $U$ is

$$U = \frac{4}{3} \frac{\pi a^3 (\rho - \rho_s) g}{6\pi a \mu} = \frac{2a^2 (\rho - \rho_s) g}{9 \mu},$$  \hspace{1cm} (8)

where $g$ is the acceleration due to gravity and $\rho_s$ is the density of the sphere. Equation (7) is the Stokes law and can be further corrected by Faxén’s laws. Considering the Faxén correction, the drag on a stationary rigid sphere in the Stokes flow is

$$F = 6\pi \mu a (U + \frac{1}{6} a^2 \nabla^2 U).$$  \hspace{1cm} (9)

The second term comes from Faxén correction. However, if the sphere reaches its terminal velocity, $\nabla^2 U = 0$, the terminal velocity is the same as (8).

3.2. Uniform Flow past a Fluid Drop

If the rigid sphere discussed above is replaced by a spherical fluid drop of radius $d$, i.e., the radius of the rigid kernel, $a$, is zero in Figure 1, this is the case for uniform flow past a fluid drop. The fluid of the drop is immiscible with the surrounding fluid and the interface is spherical. The fluid drop is moving at a constant speed through the surrounding fluid without changing its shape [37,38], or the flow is past a fixed, undeformed fluid drop. The most general expressions for the stream functions outside and inside the drop [36] are

$$\psi(r, \theta) = \sin^2 \theta \left( \frac{A}{r} + Br + Cr^2 + Dr^4 \right)$$  \hspace{1cm} (10)
and
\[
\psi(r, \theta) = \sin^2 \theta \left( \frac{A}{r} + B r + C r^2 + D r^4 \right),
\]
(11)

respectively. Here, \( A, B, C, D, \bar{A}, \bar{B}, \bar{C}, \bar{D} \) are unknown constant coefficients. From the stream functions, the velocity fields and stress tensors can be deduced with specified boundary conditions.

In the region outside the drop, the fluid velocity is asymptotic to \( u = U = U e_z \) as \( r \to \infty \).

\[
C = \frac{1}{2} U, \quad \text{and} \quad D = 0.
\]
(12)

On the drop boundary, the normal velocity is zero, \( v_r(d, \theta) = 0 \), which implies

\[
\frac{A}{d^3} + \frac{B}{d} + \frac{U}{2} = 0.
\]
(13)

Inside the drop, the fluid velocity must remain finite as \( r \to 0 \), i.e.,

\[
\bar{A} = \bar{B} = 0,
\]
(14)

and \( v_r(d, \theta) = 0 \), which requires

\[
\frac{\bar{A}}{d^3} + \frac{\bar{B}}{d} + \bar{C} + d^2 \bar{D} = 0.
\]
(15)

Two additional constraints—continuity of tangential velocity and continuity of tangential stress—are required at the interface of the two fluids. These constraints set

\[
-\frac{A}{d^3} + \frac{B}{d} + 2C + 4d^2 \bar{D} = -\frac{\bar{A}}{d^3} + \frac{\bar{B}}{d} + 2C + 4d^2 \bar{D}
\]
(16)

and

\[
\mu \frac{A}{d^4} = \mu a \bar{D}.
\]
(17)

After solving the above Equations (12)–(17), the coefficients in the stream functions are determined as

\[
A = \frac{d^3 \bar{A} U}{4(\bar{\mu} + \mu)}, \quad B = -\frac{d U(3\bar{\mu} + 2\mu)}{4(\bar{\mu} + \mu)}, \quad \bar{C} = -\frac{\mu U}{4(\bar{\mu} + \mu)}, \quad \bar{D} = \frac{\mu U}{4d^2(\bar{\mu} + \mu)}.
\]
(18)

Thus, the stream functions outside and inside the drop are

\[
\psi(r, \theta) = \frac{1}{4} U d^2 \sin^2 \theta \left( \frac{\bar{\mu}}{\mu + \bar{\mu}} \right) \frac{d}{r} - \left( \frac{2\mu + 3\bar{\mu}}{\mu + \bar{\mu}} \right) \frac{r}{d} + 2 \left( \frac{r}{d} \right)^2
\]
(19)

and

\[
\bar{\psi}(r, \theta) = \frac{1}{4} U \sin^2 \theta \left( \frac{\mu}{\mu + \bar{\mu}} \right) r^2 \left[ \left( \frac{r}{d} \right)^2 - 1 \right],
\]
(20)

respectively. This result is known as the Hadamard–Rybczyński equation [39]. Figure 3 shows streamlines in the symmetry plane for uniform flow past a fluid drop.
Figure 3. Streamlines in the symmetry plane for uniform flow past a fluid drop. The radius of the fluid drop is $d = 1$ and the viscosity ratio $\bar{\mu}/\mu = 10$.

In the limit, $\bar{\mu} \gg \mu$, in which the drop is much more viscous than the surrounding fluid, Equation (4) is recovered from the stream functions (19) and (20).

The drag on the fluid drop is predicted as

$$F_{\text{drag}} = 2\pi \mu d U \frac{2\mu + 3\bar{\mu}}{\mu + \bar{\mu}}.$$  \hspace{1cm} (21)

If the drop is falling in fluid, it reaches the terminal velocity $U$ when the forces exerted on it are balanced. So, the magnitude of the terminal velocity is

$$U = \frac{2d^2 g}{3\nu} \left(1 - \frac{\bar{\rho}}{\rho}\right) \frac{\mu + \bar{\mu}}{2\mu + 3\bar{\mu}}.$$  \hspace{1cm} (22)

where $\nu = \mu/\rho$ is the kinematic viscosity of the surrounding fluid.

3.3. Uniform Flow past a Rigid-Kernel Sphere with a Fluid Coating

For uniform flow past a rigid sphere with a fluid coating, we make similar assumptions for boundaries as in the above cases. First of all, the rigid spherical kernel with fluid coating remains spherical. Both fluids are Newtonian and mutually immiscible, and there is no interfacial mass transfer (the radial velocity is zero at the interface). Following (10) and (11), the general stream functions are proposed as

$$\psi(r, \theta) = \sin^2 \theta \left(\frac{A}{r} + Br + Cr^2 + Dr^4\right), \text{ for } r \geq R$$  \hspace{1cm} (23)

$$\tilde{\psi}(r, \theta) = \sin^2 \theta \left(\frac{\tilde{A}}{r} + \tilde{B}r + \tilde{C}r^2 + \tilde{D}r^4\right), \text{ for } a \leq r \leq R$$  \hspace{1cm} (24)

in which $A, B, \cdots, D$ are constant coefficients. Consequentially, for $r > R$,

$$v_r(r, \theta) = 2\cos \theta \left(\frac{A}{r^3} + \frac{B}{r} + C + Dr^2\right),$$

$$v_\theta(r, \theta) = -\sin \theta \left(-\frac{A}{r^3} + \frac{B}{r} + 2C + 4Dr^2\right),$$

$$\sigma_{r\theta}(r, \theta) = \sigma_{\theta r}(r, \theta) = -6\mu \sin \theta \left(\frac{A}{r^4} + Dr\right).$$
For $a < r < R$,
\begin{align*}
\dot{v}_r(r, \theta) &= 2\cos \theta \left( \frac{\dot{A}}{r^3} + \frac{\dot{B}}{r} + \dot{C} + Dr \right), \quad (28) \\
\dot{v}_\theta(r, \theta) &= -\sin \theta \left( -\frac{\dot{A}}{r^3} + \frac{\dot{B}}{r} + 2\dot{C} + 4Dr \right), \quad (29) \\
\dot{v}_{r\theta}(r, \theta) &= \dot{v}_{\theta r}(r, \theta) = -6\mu \sin \theta \left( \frac{\dot{A}}{r^4} + Dr \right). \quad (30)
\end{align*}

To determine the unknown coefficients in Equations (23) and (24), we impose the boundary conditions. Boundary conditions are evaluated at the fluid-fluid interface $r = R$, and the interface of the rigid spherical kernel and the fluid coating $r = a$.

1. The boundary condition at infinity implies
\[
C = \frac{1}{2} U \quad \text{and} \quad D = 0. \quad (31)
\]

2. The zero normal velocity at the interface of fluids $v_r(R_-, \theta) = \dot{v}_r(R_+, \theta) = 0$ sets
\[
2 \cos \theta \left( \frac{A}{R^3} + \frac{B}{R} + \frac{1}{2} U \right) = 2 \cos \theta \left( \frac{\dot{A}}{R^3} + \frac{\dot{B}}{R} + \dot{C} + DR \right) = 0. \quad (32)
\]

3. With the continuity of tangential velocity at the interface of fluids, the following equation is satisfied
\[
-\frac{A}{R^3} + \frac{B}{R} + U = -\frac{\dot{A}}{R^3} + \frac{\dot{B}}{R} + 2\dot{C} + 4Dr. \quad (33)
\]

4. The no-slip boundary condition at $r = a$ requires
\[
\frac{\dot{A}}{a^3} + \frac{\dot{B}}{a} + \dot{C} + Da^2 = 0 \quad \text{and} \quad -\frac{\dot{A}}{a^3} + \frac{\dot{B}}{a} + 2\dot{C} + 4Da^2 = 0. \quad (34)
\]

5. Continuity of tangential stress at the interface of the fluids $\sigma_{r\theta}(R_-, \theta) = \dot{v}_{r\theta}(R_+, \theta)$ implies
\[
-6\mu \sin \theta \left( \frac{A}{R^3} + DR \right) = -6\mu \sin \theta \left( \frac{\dot{A}}{R^4} + DR \right). \quad (35)
\]

Finally, combining Equations (31)–(35), we solve for the constant coefficients. The constant coefficients are attained as
\[
A = \frac{\mu R^3 U(a + R) (2a^2 + aR + 2R^2)}{8a^3(\bar{\mu} - \mu) + 6a^2R(2\bar{\mu} - \mu) + 6aR^2(2\bar{\mu} + \mu) + 8R^3(\bar{\mu} + \mu)},
\]
\[
B = \frac{-R U a^3(6\bar{\mu} - 4\mu) + a^2R(9\bar{\mu} - 3\mu) + 3aR^2(3\bar{\mu} + \mu) + 2R^3(3\bar{\mu} + 2\mu)}{8a^3(\bar{\mu} - \mu) + 6a^2R(2\bar{\mu} - \mu) + 6aR^2(2\bar{\mu} + \mu) + 8R^3(\bar{\mu} + \mu)},
\]
\[
\tilde{A} = \frac{a^3 R^2(2a + R) f(a, R, \mu, \bar{\mu})}{8a^3(\bar{\mu} - \mu) + 6a^2R(2\bar{\mu} - \mu) + 6aR^2(2\bar{\mu} + \mu) + 8R^3(\bar{\mu} + \mu)},
\]
\[
\tilde{B} = \frac{-a \left( 2a^3 + 4a^2R + 6aR^2 + 3R^3 \right) f(a, R, \mu, \bar{\mu})}{8a^3(\bar{\mu} - \mu) + 6a^2R(2\bar{\mu} - \mu) + 6aR^2(2\bar{\mu} + \mu) + 8R^3(\bar{\mu} + \mu)},
\]
\[
\tilde{C} = \frac{\left( 3a^3 + 6a^2R + 4aR^2 + 2R^3 \right) f(a, R, \mu, \bar{\mu})}{8a^3(\bar{\mu} - \mu) + 6a^2R(2\bar{\mu} - \mu) + 6aR^2(2\bar{\mu} + \mu) + 8R^3(\bar{\mu} + \mu)},
\]
\[
\tilde{D} = \frac{-\left( a + 2R \right) f(a, R, \mu, \bar{\mu})}{8a^3(\bar{\mu} - \mu) + 6a^2R(2\bar{\mu} - \mu) + 6aR^2(2\bar{\mu} + \mu) + 8R^3(\bar{\mu} + \mu)},
\]
where
\[
f(a, R, \mu, \bar{\mu}) = \frac{1}{2} \frac{\mu UR}{4a^4(\bar{\mu} - \mu) + a^3 R(2\bar{\mu} + \mu) + 6a^2\mu R^2 + aR^3(\mu - 2\bar{\mu}) - 4R^4(\bar{\mu} + \mu)}.
\]
Thus, the stream functions for the flow outside the particle and the flow inside the coating, Equations (23) and (24), are determined:

$$\psi(r, \theta) = U \sin^2 \theta \left[ \frac{r^2}{2} + \mu \frac{R(a + R) (2a^2 + aR + 2R^2)}{2} \left( \frac{R^2 - 3r^2}{4a^3(\bar{\mu} - \mu) + 3a^2R(2\bar{\mu} - \mu) + 3aR^2(2\mu + \mu) + 4R^3(\mu + \bar{\mu})} \right) \right],$$  

$$\tilde{\psi}(r, \theta) = \sin^2 \theta \left( a - r \right) \left( \frac{4a^2 + 7aR + 4R^2}{4a^3(\bar{\mu} - \mu) + 3a^2R(2\bar{\mu} - \mu) + 3aR^2(2\mu + \mu) + 4R^3(\mu + \bar{\mu})} \right).$$  

Figure 4 shows the streamlines of the fluid field outside the object and inside the fluid coating. For this figure, the radius of the rigid kernel $a = 1$, the thickness of the fluid coating $d = 1$, and the viscosity ratio of two fluids is $\bar{\mu}/\mu = 5$.

Figure 4. Streamlines in the symmetry plane for the flow field of a uniform flow past a fluid-coated rigid-kernel sphere. The black region is the rigid kernel and the gray region with circulation is the fluid coating. The viscosity ratio is $\bar{\mu}/\mu = 5$. The radius of the rigid kernel and the thickness of the fluid coating are set as $a = d = 1$.

In the limit of high viscosity stratification $\frac{\mu}{\bar{\mu}} \to 0$, Equation (4) is recovered from the stream functions (37) and (38). Even if the viscosities of two fluids are the same, $\frac{\mu}{\bar{\mu}} = 1$, the streamline pattern for this special case is still similar to the general situation shown in Figure 4. The stream functions are simplified as

$$\psi(r, \theta) = U \sin^2 \theta \left[ \frac{r^2}{2} - \frac{r \left( a^3 + 3a^2R + 6aR^2 + 5R^3 \right)}{3a^2 + 9aR + 8R^2} + \frac{R^2(a + R) \left( 2a^2 + aR + 2R^2 \right)}{2r \left( 3a^2 + 9aR + 8R^2 \right)} \right],$$  

$$\tilde{\psi}(r, \theta) = \frac{U \sin^2 \theta (a - r)^2 (R - r)}{2r(a - R)} \frac{\left( 2(a^2 + rR)(r + R) + a \left( r^2 + 5rR + R^2 \right) \right)}{3a^2 + 9aR + 8R^2}.$$

The discontinuity in the radial stress across the fluid–fluid interface is related to the surface tension of the interface at $r = R$

$$\sigma_{rr}(R_+, \theta) - \sigma_{rr}(R_-, \theta) = \frac{2\alpha}{R},$$  

(39)
where $\alpha$ is the surface tension [36,39]. As long as the drop moves at the constant terminal velocity $U$, all constraints at the interface between the two fluids are completely satisfied. This fact validates the previous assumptions that the interface is spherical and the drop moves constantly through the surrounding fluid at a constant speed without changing its shape. This is different from the sphere coated with a thin film studied by Johnson [19]. For the thin film results, the surface tension force is larger than the viscous force, and “the mechanism driving the fluid circulation within the film is not too large.” The radial velocity in the thin film is assumed to be one order lower than the tangential velocity for the asymptotic analysis. Furthermore, global force equilibrium has also been proposed for the thin fluid film. The above assumptions are relaxed in our problem. The compound particle is held as spherical with enough surface tension. However, the surface tension in Equation (39) may be significant and is important for the stability of the problem. It would be important to further analyze the stability and the Magrangoni effect—which is totally neglected—in the future work.

3.4. Hydrodynamic Drag Force and Terminal Velocity

Hydrodynamic drag force is of fundamental interest for the flow being examined. The drag force is evaluated by integrating the surface stress vector over the body surface. For this axisymmetric problem, the integration can be carried out explicitly.

According to the results (37) and (38), the Stokes force $F_{\text{drag}}$ exerted on a stationary spherical particle immersed in the uniform Stokes flow field $U$ are

$$F_{\text{drag}} = \frac{4\pi\mu RU^3}{4\lambda^3(\mu - \mu) + 3a^2R^2(2\mu - \mu) + 3aR^2(3\mu + \mu) + 2R^3(3\mu + 2\mu)}.$$ (40)

Note the viscosity ratio as $\lambda = \frac{\mu}{\mu}$ and the volume fraction in terms of ratio $\gamma = \frac{a}{R}$. After nondimensionalizing the drag with a dimensional factor $4\pi\mu RU$, the non-dimensional drag force is

$$F(\lambda, \gamma) = \frac{F_{\text{drag}}}{4\pi\mu RU} = \frac{\gamma^3(6\lambda - 4) + \gamma^2(9\lambda - 3) + 3\gamma(3\lambda + 1) + 2(3\lambda + 2)}{4\gamma^3(\lambda - 1) + 3\gamma^2(2\lambda - 1) + 3\gamma(2\lambda + 1) + 4(\lambda + 1)}.$$ (41)

Figures 5 and 6 show the dimensionless drag $F(\lambda, \gamma)$ with one variable fixed. Figure 5 demonstrates the dimensionless drag $F(\lambda, \gamma)$ as a function of the viscosity ratio $\lambda$ with the volume fraction $\gamma^3$ fixed. With the fluid coating, the object experiences less drag on it. The outcome is consistent with other studies [19,26]. When the viscosity ratio approaches the limit $\lambda \to \infty$, the object behaves like a rigid sphere with radius $R$, which implies the volume fraction $\gamma = 1$ case. The drag force satisfied the Stokes drag Equation (7) reviewed in Section 3.1.

![Figure 5](image-url)

**Figure 5.** Loglog plot of the dimensionless drag force $F(\lambda, \gamma)$ as a function of the viscosity ratio $\lambda$ with fixed values of the volume fraction, $\gamma^3$. 
The dependence of the dimensionless drag $F(\lambda, \gamma)$ on the volume fraction $\gamma^3$ is depicted in Figure 6. In the limiting case of $\gamma = 1$, the result for the solid sphere is recovered. Given the viscosity ratio $\lambda$, the dimensionless drag force decreases if the volume of the fluid coating increases. When the viscosity ratio is small and the volume fraction goes to the limit $\gamma \to 0$, the result is asymptotic to the fluid drop result (21) in Section 3.2.

When the sphere reaches its terminal velocity $U$, the forces acting on the sphere are balanced, i.e.,

$$F = \frac{4\pi}{3} R^3 (\rho - \bar{\rho}) g - \frac{4\pi}{3} a^3 (\rho_s - \bar{\rho}) g.$$ (42)

Here, $\rho$, $\bar{\rho}$ and $\rho_s$ are density for the background flow, the fluid coating and the rigid kernel, respectively. Applying the results for hydrodynamic force in (40) to (42), we can calculate the terminal velocity of such a freely falling spherical object

$$U = \frac{R^3 (\rho - \bar{\rho}) - a^3 (\rho_s - \bar{\rho})}{3\mu R} \cdot \frac{4a^3 (\bar{\mu} - \mu) + 3a^2 R (2\bar{\mu} - \mu) + 3aR^2 (2\bar{\mu} + \mu) + 4R^3 (\bar{\mu} + \mu)}{a^3 (6\bar{\mu} - 4\mu) + a^2 R (9\bar{\mu} - 3\mu) + 3aR^2 (3\bar{\mu} + \mu) + 2R^3 (3\mu + 2\mu)} g.$$ (43)

To compare the terminal velocity of this compound particle with a rigid sphere or a fluid drop, the densities of the fluid in the coating and the rigid kernel are both set as the mean density $\rho_{\text{mean}} = \bar{\rho} + \gamma^3 (\rho_s - \bar{\rho})$. Therefore, their masses and volumes are the same. Then, from (43), the terminal velocity of the compound particle is

$$U = \frac{R^2 g \rho}{3\mu} (1 - \kappa) \left[ \frac{4\gamma^3 (\lambda - 1) + 3\gamma^2 (2\lambda - 1) + 3\gamma (2\lambda + 1) + 4(\lambda + 1)}{\gamma^3 (6\lambda - 4) + \gamma^2 (9\lambda - 3) + 3\gamma (3\lambda + 1) + 2(3\lambda + 2)} \right].$$ (44)

where $\kappa = \frac{\rho_{\text{mean}}}{\rho}$. Nondimensionalize the terminal velocity,

$$Un = \frac{U}{\frac{2R^2 g \rho}{3\mu} (1 - \kappa)} = \frac{3}{2} \left[ \frac{4\gamma^3 (\lambda - 1) + 3\gamma^2 (2\lambda - 1) + 3\gamma (2\lambda + 1) + 4(\lambda + 1)}{\gamma^3 (6\lambda - 4) + \gamma^2 (9\lambda - 3) + 3\gamma (3\lambda + 1) + 2(3\lambda + 2)} \right].$$ (45)
in which $\frac{2R^2 \rho}{\kappa}$ is the terminal velocity of the corresponding rigid sphere from (8). Applying the same nondimensionalization, we know the terminal velocity of the rigid sphere and fluid drop are

for a rigid sphere, \[ Un = 1, \]
for a fluid drop, \[ Un = 3 \left( 1 + \frac{\lambda}{2 + 3\lambda} \right). \]

Figure 7 shows the nondimensionless terminal velocities for those objects. With this figure, the transition and the asymptotic behavior to two limit cases, i.e., a rigid sphere and a fluid drop, are demonstrated well. It is interesting to see that by selecting the volume fraction and viscosity of fluids, the designed terminal can be targeted. This is an important feature for the drug delivery applications.

![Figure 7](image-url)

**Figure 7.** The dimensionless terminal velocity $Un(\lambda, \gamma)$ as a function of the viscosity ratio $\lambda$ with fixed volume fraction $\gamma^3$. The densities of the fluid in the coating and the rigid kernel are set the same as the mean density $\rho_{\text{mean}}$. The radii of the two-layer object, the rigid sphere, the fluid drop, and the air bubble are the same. The air bubble result is obtained by taking the viscosity ratio $\lambda = \bar{\mu}/\mu = 0$ for the fluid drop.

### 3.5. Multiple-Layer Fluid Coating

Under similar assumptions for the particle and the properties of fluids, we assume the rigid kernel is covered by two or three layers of fluid coating. Between adjacent layers, boundary conditions (32)–(35) hold with their corresponding fluid viscosities. The same type of stream function is proposed in each fluid coating layer. When a new layer is added, four more unknown coefficients are introduced in the stream function. These four coefficients are coupled with the coefficients in the stream function of the fluid coating layer(s) next to it. To solve this fluid problem, a linear system for the unknown coefficients is constructed. When the unknowns are arranged in a particular way, a block tridiagonal matrix arises. The reason to arrange the unknowns in a certain order is to achieve the resulting efficiencies. For example, solution algorithms are most efficient if these patterns are taken into account in the LU decomposition. Once we obtain the unique coefficients, the analytical formulae for the stream functions can be written out. Further analysis about the flow field is possible.
For a sphere with a rigid kernel and one layer of fluid coating discussed before \((n = 1, \text{ see Figure 1})\), the linear system is the combination of Equations (31)–(35):

\[
\begin{pmatrix}
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
\frac{1}{R^2} & \frac{1}{R} & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{\mu} & 0 & 0 & \mu R & 0 & 0 & 0 & 0 \\
-\frac{1}{R^2} & \frac{1}{R} & 2 & 4R^2 & \frac{1}{R^2} & \frac{1}{R} & -2 & -4R^2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \frac{1}{\mu} & \frac{1}{R^2} & \frac{2}{a^2} & 4a^2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{pmatrix}
\begin{pmatrix}
A \\
B \\
C \\
D \\
\end{pmatrix}
=
\begin{pmatrix}
\frac{U}{2} \\
0 \\
0 \\
0 \\
\end{pmatrix}.
\tag{46}
\]

It is easy to see that we can eliminate the unknowns \(C = \frac{U}{2}\) and \(D = 0\), even for the other cases. However, they are saved to illustrate that the number of unknown coefficients grows arithmetically and four unknown coefficients are associated with each fluid layer, even the unbounded region outside the particle. As the determinant of the coefficient matrix is not equal to zero, the system is invertible. The coefficients are uniquely determined and the solution is non-trivial as documented in Equation (36).

For a spherical particle with a rigid kernel and two-layer fluid coating, Figure 8a shows the diagram of the problem. Radii for the fluid coating satisfy \(a \leq R_1 \leq R\). Keep \(\{A, B, C, D\}\) for the stream function outside the particle and \(\{\tilde{A}, \tilde{B}, \tilde{C}, \tilde{D}\}\) for the inner layer next to the rigid kernel, as the previous case. Note \(\{A_1, B_1, C_1, D_1\}\) as the coefficients for the stream function of the outer layer \((R_1 \leq r \leq R)\). The viscosity of fluid outside the particle is \(\mu; \tilde{\mu}\) is the viscosity of the fluid in the layer \(a \leq r \leq R_1\), and the new parameter \(\mu_1\) is for the fluid in the layer \(R_1 \leq r \leq R_2\). To attain the analytical solution, we collect the boundary conditions in terms of the unknowns. The linear system for the unknowns is

\[
T_1 \begin{pmatrix}
A & B & C & D & A_1 & B_1 & C_1 & D_1 & \tilde{A} & \tilde{B} & \tilde{C} & \tilde{D}
\end{pmatrix}^T = \begin{pmatrix}
\frac{U}{2} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}^T,
\tag{47}
\]

where the coefficient matrix is

\[
T_1 = \\
\begin{pmatrix}
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{R^2} & \frac{1}{R} & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{\mu} & 0 & 0 & \mu R & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-\frac{1}{R^2} & \frac{1}{R} & 2 & 4R^2 & \frac{1}{R^2} & \frac{1}{R} & -2 & -4R^2 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & \frac{1}{\mu} & \frac{1}{R^2} & \frac{2}{a^2} & 4a^2 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{\mu}{R^2} & 0 & 0 & \mu R_1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{\mu_1 R_1}{R^2} & -\frac{\mu}{R^2} & 0 & 0 & -\mu R_1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -\frac{1}{\mu} & \frac{1}{R^2} & 2 & 4R^2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -\frac{1}{\mu} & \frac{1}{R^2} & \frac{2}{a^2} & 4a^2 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{pmatrix}
\]

and

\[\det(T_1) \neq 0.\]
The entries in terms of the new layer radius $R_1$ are highlighted in the matrix, and the block matrices on the diagonal are marked out. The coefficient matrix can be viewed as a block tridiagonal matrix.

$$
\begin{pmatrix}
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{R^2} & \frac{1}{R} & 1 & R^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-\frac{1}{\mu R} & 0 & 0 & -\mu_R & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
-\frac{1}{\mu R} & -\frac{1}{R} & -2 & -4R^2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & \mu_R & 0 & 0 & \mu_R & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{\mu R} & \frac{1}{R} & \frac{1}{R} & 2 & 4R^2 & \frac{1}{\mu R} & \frac{1}{R} & -2 & -4R^2 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\frac{1}{\mu R} & \frac{1}{R} & \frac{1}{R} & 2 & 4R^2 & \frac{1}{\mu R} & \frac{1}{R} & -2 & -4R^2 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
\end{pmatrix}
$$

The entries in terms of the new layer radius $R_2$ are highlighted in the matrix. Since the determinant of this coefficient matrix is not equal to zero, the unknown coefficients in the stream functions can be uniquely determined.

The above results show the analytical solution, i.e., the stream function, is well defined when we propose the ideal conditions for the fluids and boundaries. In reality, these conditions may not be physical preferred. However, such solutions could be used as the fundamental solution to further explore the complicated situations. In general, we can keep adding more layers to the fluid coating. The solvability for a general N-layer fluid coating is an interesting linear algebra problem and will be reported in a future study.
4. Summary and Future Directions

In this paper, we have studied a uniform flow past a spherical compound object in the Stokes regime. The object consists of a rigid kernel with a fluid coating. Rigorous analytical solutions are presented for different cases. The explicit stream functions are derived for both the fluid flow outside the object and the fluid flow inside the coating layer. The resulting plots of the streamlines show the circulation inside the fluid coating. From the stream functions, we obtained the explicit drag force and discussed terminal velocity of the object.

The results show that, given a fixed size, the spherical object, with a rigid kernel and covered with a fluid coating, experiences less drag than a pure rigid object, if they have the same mass and same volume. This finding is valuable to biomedical applications, as drag is closely related to the energy required to keep the object in motion.

This study is fundamental. The analytical results provide the basis to investigate the stability of the problem. With the exact solutions, the study of flow patterns can be extended to the bifurcation of the flow field and the Marangoni effect can be further explored. Such analytical results will also be critical to a future study of more complicated systems. For example, results reported in this paper will provide the solution for fluid in which chemical reactions are coupled with hydrodynamics when oxygen is pumped in flow past an oocyte [32].
