### Message from the Guest Editors

#### Dear Colleagues,

Cardiovascular diseases are frequent among elderly patients. It is estimated that 70% of the population over 70 will develop cardiovascular diseases. People older than 65 are more likely to suffer acute coronary syndrome, experience a stroke, or develop coronary artery disease and heart failure. The geriatric population has grown worldwide in recent decades because life expectancy has increased significantly. However, the aged population is underrepresented in clinical trials, and current clinical practice guidelines do not include specific recommendations. They are also a heterogeneous group that ranges from robust and independent individuals to those who may experience additional complications such as polypharmacy, frailty, comorbidities, or inflammation.

Thus, in this Special Issue, we welcome contributions focused on various domains related to cardiovascular disease in the elderly, in order to improve the management of elderly patients with acute coronary syndrome and other cardiovascular diseases.
