Deadline for manuscript submissions: 30 September 2017

Message from the Guest Editors

It has been known for almost four decades that surface acoustic wave (SAW) and, more recently, bulk acoustic wave (BAW) devices can be used as sensors for a multitude of measurements. Physical, chemical, or biological sensors, based on microacoustics, show some distinct advantages compared to other technologies: They are mainly based on oxide ceramics and metals and, thus, can withstand higher temperatures than silicon. Their output signals such as frequency and phase lend themselves well to digital measurement; and they are typically operated at frequencies also used in mobile communications and can be interrogated wirelessly. However, there do not exist many commercial systems based on SAW or BAW sensors. This Special Issue serves to explore the state-of-the-art of the technology and to identify possible routes for further work that might help to overcome innovation hurdles.

- SAW/BAW sensors
- SAW/BAW sensor modeling and signal processing
- signal conditioning
- design and fabrication
- novel applications

Author Benefits

Open Access: free for readers, with publishing fees paid by authors or their institutions.

High visibility: indexed by the Science Citation Index Expanded (Web of Science), MEDLINE (PubMed), EI Compendex, INSPEC (IET) and other databases.

Rapid publication: manuscripts are peer-reviewed and a first decision provided to authors approximately 30 days after submission; acceptance to publication is undertaken in 6 days (median values for papers published in this journal in 2016).

Sections: published in five topical sections.
