### **Message from the Guest Editors**

Chagas disease is a neglected tropical disease caused by the protozoan parasite *Trypanosoma cruzi*. This kinetoplastid parasite has a complex life cycle involving susceptible hosts and the triatomine insect vector, as well as certain mammals (e.g., opossum). Infection is found throughout the Americas and occurs via several routes of exposure, including the vector-borne, congenital, and even oral consumption of contaminated food and drink products.

Improving our understanding of the incidence, prevalence, and risk factors for Chagas disease is key to informing public health programs addressing this highly neglected disease.

The scope of this Special Issue shall encompass the following:

- New research focused on the epidemiology of Chagas disease in endemic and non-endemic regions of the Americas;
- Triatomine biology and distribution in the Americas;
- *Trypanosoma cruzi* infection among susceptible sylvatic, peridomestic, and domestic animal hosts;
- Programs to improve awareness and access to care among those at risk for Chagas disease in the Americas.
