Isolation and characterization of fungal materials

The isolation of pure cultures was performed immediately after the fungal specimens were collected. Briefly, agar plug of potato dextrose agar (PDA) containing 50 mg/L penicillin and streptomycin were cut into small pieces and then gently swiped over the spores located on synnemata using a fine sterile needle. Agar plugs with spores were placed on PDA containing antibiotics which was then incubated at 25 °C and the conidial germination was observed daily as well as fungal contamination. Pure cultures were isolated onto fresh PDA plate without antibiotics by hyphal tip isolation, allowed to grow for 4-6 weeks and subsequently deposited to Prince of Songkla University and BIOTEC, Thailand with the BCC code no. BCC47869 (EPF036), BCC47876 (EPF057), BCC47877 (EPF063), BCC47878 (EPF068), BCC47880 (EPF070), BCC47881 (EPF071), BCC47894 (EPF097) and BCC47895 (EPF098).

Figure S1. Morphological characteristics of *A. novoguineensis*. *A. novoguineensis* BCC47881 and its colonies on PDA at 25 °C for 16 days (A-C), BCC47894 and its colonies on PDA at 25 °C for 11 days (D-F), part of synnema showing phialides (G-H), conidia (I), Scale bar: G = 500 µm, H-I = 10 µm

The producing strains were characterized as *Akanthomyces novoguineensis* according to Samson and Brady [1], Hywel-Jones [2] and Hsieh et al. [3] by producing 2-5 creamish white, erect, cylindrical synnemata on the hosts (Figure S1). The globose, hyaline, smooth-walled phialides, each with a single

distinct neck were located scattering along the entire length of synnema (Figure S1). The conidia forming at the tip of the neck were hyaline and ellipsoid (Figure S1). On PDA, the white to cream colonies were slow-growing, reaching a diameter of 0.8-1.0 cm in 14 days at 25 °C. The colony reverse was pink or yellowish-orange with diffused pale pink or yellow pigment in the agar (Figure S1). Sporulation was not found.

Based on the nucleotide-nucleotide search using the Basic Local Alignment Search Tool (BLAST) from the National Center for Biotechnology Information (NCBI, USA), the ITS rDNA sequences of the producers were most closely related to *A. novoguineensis* and the strain BCC41865 (GenBank accession no. JN201872) was the top BLAST match with 99% identity for all isolates except BCC47894 (97% identity).

According to morphological features and the BLAST search results, the species could be identified as *A. novoguineensis*.

Table S1. A list of species of Cordycipitaceae in which akanthopyrones [4] and compounds **1-5** were not detected in their EtOAc extracts (4.5 mg/mL) of fermentation broths using HPLC profiling. The fungal isolates were cultured in YMG medium (yeast extract, 4 g; malt extract, 10 g; D-glucose, 4 g; distilled water, 1,000 mL) or PDB supplemented with 0.1% of yeast extract or both.
