## Comment

The displacement ellipsoids were drawn at the $50 \%$ probability level.

## Experimental

A colorless, plate-shaped crystal of dimensions $0.044 \times 0.196 \times 0.258 \mathrm{~mm}$ was selected for structural analysis. Intensity data for this compound were collected using a D8 Quest к-geometry diffractometer with a Bruker Photon II CMOS area detector [1,2] and an Incoatec I $\mu$ s microfocus Mo K $\alpha$ source ( $\lambda=0.71073 \AA$ ). The sample was cooled to $100(2) \mathrm{K}$. Cell parameters were determined from a least-squares fit of 7723 peaks in the range $2.85<\theta<28.73^{\circ}$. A total of 21066 data were measured in the range $2.848<\theta<28.786^{\circ}$ using $\phi$ and $\omega$ oscillation frames. The data were corrected for absorption by the empirical method [3] giving minimum and maximum transmission factors of 0.6236 and 0.7458 . The data were merged to form a set of 3242 independent data with $\mathrm{R}(\mathrm{int})=0.0490$ and a coverage of $99.8 \%$.

The orthorhombic space group $P 2{ }_{12}{ }_{12} 21$ was determined by systematic absences and statistical tests and verified by subsequent refinement. The structure was solved by direct methods and refined by full-matrix least-squares methods on $F^{2}[4,5]$. The positions of hydrogens bonded to carbons were initially determined by geometry and were refined using a riding model. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atom displacement parameters were set to 1.2 times the isotropic equivalent displacement parameters of the bonded atoms. A total of 172 parameters were refined against 3242 data to give $\mathrm{wR}\left(F^{2}\right)=0.0766$ and $S=1.007$ for weights of $\mathrm{w}=1 /\left[\sigma^{2}\left(F^{2}\right)+(0.0220 \mathrm{P})^{2}+0.4000 \mathrm{P}\right]$, where $\mathrm{P}=\left[F \mathrm{o}^{2}+2 F \mathrm{c}^{2}\right] / 3$. The final $\mathrm{R}(F)$ was 0.0352 for the 2932 observed, $[F>4 \sigma(F)]$, data. The largest shift/s.u. was 0.000 in the final refinement cycle. The final difference map had maxima and minima of 0.149 and $-0.174 \mathrm{e} / \AA^{3}$, respectively. The absolute structure was determined by refinement of the Hooft parameter [7].

The displacement ellipsoids were drawn at the $50 \%$ probability level.

## Experimental

A yellow, plate-shaped crystal of dimensions $0.028 \times 0.152 \times 0.248 \mathrm{~mm}$ was selected for structural analysis. Intensity data for this compound were collected using a D8 Quest к-geometry diffractometer with a Bruker Photon II CMOS area detector [1,2] and an Incoatec I $\mu$ s microfocus Mo K $\alpha$ source ( $\lambda=0.71073 \AA$ ). The sample was cooled to $100(2) \mathrm{K}$. Cell parameters were determined from a least-squares fit of 7081 peaks in the range $2.76<\theta<25.64^{\circ}$. A total of 21764 data were measured in the range $2.758<\theta<25.821^{\circ}$ using $\phi$ and $\omega$ oscillation frames. The data were corrected for absorption by the empirical method [3] giving minimum and maximum transmission factors of 0.5330 and 0.6463 . The data were merged to form a set of 2763 independent data with $R($ int $)=0.0762$ and a coverage of $99.9 \%$.

The monoclinic space group Cc was determined by systematic absences and statistical tests and verified by subsequent refinement. The structure was solved by dual-space methods and refined by full-matrix least-squares methods on $F^{2}[4,5]$. The positions of hydrogens bonded to carbons were initially determined by geometry and were refined using a riding model. The hydrogens bonded to N3 was located on a difference map, and its position was refined independently. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atom displacement parameters were set to 1.2 times the isotropic equivalent displacement parameters of the bonded atoms. A total of 212 parameters were refined against 2 space group restraints and 2763 data to give $w R\left(F^{2}\right)=0.1163$ and $S=1.046$ for weights of $w=1 /\left[\sigma^{2}\right.$ $\left.\left(F^{2}\right)+(0.0600 \mathrm{P})^{2}+0.8600 \mathrm{P}\right]$, where $\mathrm{P}=\left[F_{\mathrm{o}^{2}}+2 F \mathrm{c}^{2}\right] / 3$. The final $\mathrm{R}(F)$ was 0.0462 for the 2261 observed, $[F>$ $4 \sigma(F)$ ], data. The largest shift/s.u. was 0.000 in the final refinement cycle. The final difference map had maxima and minima of 0.241 and $-0.229 \mathrm{e} / \AA^{3}$, respectively. The absolute structure could not be determined by refinement of the Flack parameter [6].

The displacement ellipsoids were drawn at the $50 \%$ probability level.

## Experimental

A colorless, block-shaped crystal of dimensions $0.106 \times 0.272 \times 0.280 \mathrm{~mm}$ was selected for structural analysis. Intensity data for this compound were collected using a D8 Quest к-geometry diffractometer with a Bruker Photon II CMOS area detector [1,2] and an Incoatec I $\mu$ s microfocus Mo K $\alpha$ source ( $\lambda=0.71073 \AA$ ). The sample was cooled to $110(2) \mathrm{K}$. Cell parameters were determined from a least-squares fit of 9898 peaks in the range $2.91<\theta<32.61^{\circ}$. A total of 39073 data were measured in the range $2.468<\theta<32.644^{\circ}$ using $\phi$ and $\omega$ oscillation frames. The data were corrected for absorption by the empirical method [3] giving minimum and maximum transmission factors of 0.7806 and 0.8623 . The data were merged to form a set of 6040 independent data with $\mathrm{R}(\mathrm{int})=0.0288$ and a coverage of $99.9 \%$.
The orthorhombic space group P212121 was determined by systematic absences and statistical tests and verified by subsequent refinement. The structure was solved by direct methods and refined by full-matrix least-squares methods on $F 2$ [4,5]. The positions of hydrogens were initially determined by geometry and were refined using a riding model. Non-hydrogen atoms were refined with anisotropic displacement parameters. Hydrogen atom displacement parameters were set to 1.2 (1.5 for methyl) times the isotropic equivalent displacement parameters of the bonded atoms. A total of 227 parameters were refined against 6040 data to give $\mathrm{wR}\left(F^{2}\right)=0.0896$ and $S=1.005$ for weights of $w=1 /\left[\sigma^{2}\left(F^{2}\right)+(0.0580 \mathrm{P})^{2}+0.2000 \mathrm{P}\right]$, where $\mathrm{P}=\left[F \mathrm{o}^{2}+2 F \mathrm{c}^{2}\right] / 3$. The final $\mathrm{R}(F)$ was 0.0322 for the 5695 observed, $[F>4 \sigma(F)]$, data. The largest shift/s.u. was 0.000 in the final refinement cycle. The final difference map had maxima and minima of 0.357 and 0.192 e/Å3, respectively. The absolute structure was determined by refinement of the Hooft parameter [8], Hooft $\mathrm{y}=0.21(12), \mathrm{P} 2($ true $)=1.000, \mathrm{P} 3$ (true) $=0.816, \mathrm{P} 3($ rac-twin $)=0.184, \mathrm{P} 3($ false $)=0.2 \mathrm{E}-08$.
