#### Abstract

Four couples of 5,6-membered bis(metallacyclic) Pt (II) complexes with acetylide and isocyanide auxiliary ligands have been prepared and characterized. The structures of $(-)-2$ and $(-)-3$ are confirmed by single-crystal X-ray diffraction, showing a distorted square-planar coordination environment around the $\mathrm{Pt}(\mathrm{II})$ nucleus. Both solutions and solid samples of all complexes are emissive at RT. Acetylide-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes have a lower energy emission than those isocyanidecoordinated ones. The emission spectra of $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ derivatives show a lower energy emission maximum relative to $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$-coordinated complexes with the same auxiliary ligand. Moreover, the difference between cyclometalated $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ and $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ ligands exerts a more remarkable effect on the emission than the auxiliary ligands acetylide and isocyanide. Cytotoxicity and cell imaging of luminescent 5,6-membered bis(metallacyclic) Pt (II) complexes have been evaluated.

Keywords: platinum(II) complexes; 5,6-membered bis(metallacycle); biological activities; emission; crystal structures

## 1. Introduction

Cyclometalated $\mathrm{N}^{\wedge} \mathrm{C}^{\wedge} \mathrm{N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime \wedge} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes have received significant attention recently due to their great potential in chemical, biological, and optoelectronic applications [1-6]. When the classical five-membered metallacycle ( $\mathrm{C}^{\wedge} \mathrm{N}$ ) is extended to a six-membered chelating metallacycle ( $\mathrm{C}^{*} \mathrm{~N}$ ) using an amine connector, $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes show a much more perfect square-planar geometry compared to $\mathrm{N}^{\wedge} \mathrm{C}^{\wedge} \mathrm{N}^{\prime}-$ and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime}{ }^{\wedge} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes [7,8]. Through tuning coordination geometry, the rectified square structure of a 5,6-membered bis(metallacycle) may maximize the strength of the ligand field and minimize the nonradiative metal-centered transitions, so $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}-, \mathrm{N}^{*} \mathrm{~N}^{\prime} \mathrm{C}^{-}$-, and $\mathrm{C}^{\wedge} \mathrm{N}^{*} \mathrm{~N}^{\prime}$-coordinated complexes are highly emissive with an appreciable emission quantum efficiency $\left(\Phi_{\mathrm{em}}\right)$ [9,10]. Strassert et al. investigated oxygen-sensing behaviors of porous materials that phosphorescent $\left(\mathrm{C}^{\wedge} \mathrm{N}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Pt}(\mathrm{II})$ complexes encapsulated in Zn -based metal-organic frameworks [11]. In addition, Huo et al. demonstrated that a 5,6-membered bis(metallacycle) of platinum complexes could be selectively formed through either the $\mathrm{sp}^{2}$ or the $\mathrm{sp}^{3} \mathrm{C}-\mathrm{H}$ bond activation, which can be used in selective $\mathrm{C}-\mathrm{H}$ bond activation, $\mathrm{C}-\mathrm{N}$ bond cleavage, and selective acylation [12-14].

Although the square geometry is improved by forming a 5,6-membered bis(metallacycle), introducing a 5,6-membered bis(metallacycle) would increase molecular flexibility, which is adverse to the emission efficiency. The rectified geometry may alone seem not to result in a large $d$ orbital splitting enough to eliminate thermally accessible nonradiative $\mathrm{d}-\mathrm{d}$ transition, and $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ chloride complexes may be weakly emissive $[7,8]$. Acetylide and isocyanide ligands induce a much stronger ligand field than the
chloride, which could efficiently raise the nonradiative $d-d$ transition to higher energy, leading to a big jump in emission efficiency in cyclometalated $\mathrm{N}^{\wedge} \mathrm{C}^{\wedge} \mathrm{N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime \wedge} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes [15,16]. Therefore, introducing strong donors such as acetylide and isocyanide may be a suitable alternative. The emissions of $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ phenylacetylene and isocyanide derivatives are highly intensive, with $\Phi_{\mathrm{em}}$ exceeding $40 \%$ [9]. The phosphorescent phenylacetylene derivatives could be utilized as triplet photosensitizers for triplet-triplet annihilation upconversion [10].

In previous work, we reported a series of pinene-fused $\mathrm{N}^{\wedge} \mathrm{C}^{\wedge} \mathrm{N}^{\prime}-, \mathrm{N}^{\wedge} \mathrm{N}^{\prime \wedge} \mathrm{C}-, \mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}-$, and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes and investigated their solvent-, mechano-, vapor-, and thermo-induced color, luminescent, and chiroptical switching behaviors [17-19]. Pinenecontaining $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes displayed significant AIE properties in the THF-water solution system by restricting intramolecular vibration and rotation in the poor solvent. A reversible mechanochromic luminescence was found for the $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ chloride complex, and its potential utility in an anti-counterfeiting application was attempted [19]. As an extension, acetylide and isocyanide ligands are introduced in pinene-containing $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated Pt (II) complexes (Scheme 1). Four pairs of 5,6-membered bis(metallacyclic) Pt(II) complexes were characterized by NMR, HRMS, and elemental analysis, and the structures of $(-)-2$ and $(-)-3$ were unambiguously confirmed by single-crystal X-ray diffraction. We studied all obtained complexes' photophysical and luminescent properties and explored their cytotoxic properties and applications in cell imaging.

Scheme 1. Synthesis of cyclometalated $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes.

## 2. Results and Discussion

### 2.1. Synthesis and Characterization

The pinene-containing $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ precursors $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}$ and $\operatorname{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right) \mathrm{Cl}$ featuring a fused 5,6-membered bis(metallacycle) were prepared according to our reported procedures via Kröhnke strategy and palladium-catalyzed C-N crosscoupling or Cu -catalyzed N -arylation reaction [19]. Cationic $\mathrm{Pt}(\mathrm{II})$ isocyanide derivatives $(-)-1$ and $(-)-2$ were obtained through ligand metathesis reaction between 5,6 -membered bis(metallacyclic) chloride precursors and the isocyanide in the presence of AgOTf [18]. Neutral $\mathrm{Pt}(\mathrm{II})$ acetylide complexes $(-)-3$ and $(-)-4$ can be separated by reacting chloride precursors with phenylacetylene [9,20]. NMR (Figures S1-S8), HRMS Figures S9-S12), and EA
accurately determined all the target products. Compared to those of the chloride precursors $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}$ and $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right) \mathrm{Cl}$, aromatic proton signals of the complexes incorporating isocyanide and acetylide are shifted upfield. Due to $N$-phenyl presence, more aromatic proton signals are observed in 5,6-membered bis(metallacyclic) platinum(II) complexes relative to 5,5 -membered counterparts. Characteristic aliphatic proton signals of pinene groups in the high-field regions $(0.6-3.5 \mathrm{ppm})$ are perceived, with $-\mathrm{CH}_{3}$ of the pinene skeleton located at ca. 0.70 and 1.45 ppm . Moreover, structures of $(-)-2$ and $(-)-3$ were confirmed by single-crystal X-ray diffraction. The enantiomers (+)-1, (+)-2, (+)-3, and (+)-4 were also prepared using the same method.

### 2.2. Crystal Structures

The crystals suitable for X-ray diffraction were separated in mixed $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /acetone $(v / v=1: 1)$ solutions. The yellow blocks of complex $(-)-2$ crystallize in the $P 1$ space group of the triclinic system, while the yellow ones of complex $(-)-3$ are located in the $P 2_{1}$ space group of the monoclinic system (Table 1). Both yellow crystals emit orange-yellow luminescence under UV radiation $(\lambda=365 \mathrm{~nm})$. As shown in Figure 1, two molecules involved in the unit cell of both $(-)-2$ and $(-)-3$ present as an antiparallel-aligned dimer through weak $\pi-\pi$ contacts ( $3.9 \AA$ ) between electron-deficient pyridine ring and electronrich phenyl moiety using a head-to-tail fashion.

Figure 1. Crystal structures of $(-)-2$ and $(-)-3$.
As listed in Table S1, the bond distances and bond angles between $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes show a distinct difference. The Pt-C(aryl) distances (2.050(8) and 2.052(8) $\AA$ ) and Pt-C(isocyanide) distances (1.89(2) and 1.97(2) $\AA$ ) of ( - )2 are comparable to those in the reported $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime \wedge} \mathrm{C}\right) \mathrm{C} \equiv \mathrm{N}$ derivatives [21-23]. Due to chelating ring strain, $\mathrm{Pt}-\mathrm{C}($ aryl $)$ bond lengths are close to $\mathrm{Pt}-\mathrm{N}($ trans position) distances. For complex (-)-3, two carbon atoms are located at a trans position, and Pt-C(aryl) distances (1.994(9) and 1.986(9) A) differ Pt-C(isocyanide) bonds (2.049(10) and 2.053(9) A) by less than $0.05 \AA$, owing to a stronger ligand of the aryl carbon atom [9,24]. Both Pt atoms in complexes $(-)-2$ and $(-)-3$ reside in a distorted square-planar environment. However, the tridentate chelating strain in the flexible 5,6-membered bis(metallacycle) is relieved relative to the five-five-membered ring, correspondingly the degree of distortion in $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes is alleviated [7-9,19]. In addition, the C1-Pt1-N1 and C3-Pt2-N3 chelating angles (171.9(6) and $\left.172.7(6)^{\circ}\right)$ in $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated ( - )-2 are close to more linearity compared with those angles (168.0(4) and $\left.168.7(4)^{\circ}\right)$ in $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$-coordinated (-)-3 (Table S2).

The isocyanide aryl ring is almost coplanar with the $\operatorname{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right)$ moiety in $(-)-2$ with dihedral angles being 0.948 and $2.643^{\circ}$ (Figure S13), which resembles those in cyclometalated $\mathrm{Pt}(\mathrm{II})$ isocyanide complexes [21-23]. In contrast, phenylacetylene is commonly twisted with $\mathrm{Pt}(\mathrm{II})$ coordination plane, and the torsion angles between phenylacetylene and $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right)$ unit in ( - )-3 are 36.817 and $41.976^{\circ}$ [9]. Moreover, the $\mathrm{Pt}-\mathrm{C}($ alkynyl) bond bends distinctly away from the $\operatorname{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right)$ plane with a distance of $0.32 \AA$ between the C (alkynyl) atom and the plane, while the C (isocyanide) atom deviates from the $\operatorname{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right)$ plane by 0.18 and $0.10 \AA$ (Figure S14). To minimize the steric interaction between the uncyclometalated $N$-phenyl and neighboring cyclometalated aryl groups in flexible 5,6-membered bis(metallacyclic) $\operatorname{Pt}($ II $)$ complexes [7-9,19], the $N$-phenyl group is significantly twisted with the $\mathrm{Pt}(\mathrm{II})$ coordination plane with torsion angles extending from $73.15^{\circ}$ to $79.71^{\circ}$ 。 (Figure S15). The amino nitrogen in a flexible six-membered metallacycle is $0.20-0.37 \AA$ from the platinum-centered plane (Figure S14). No substantial intermolecular Pt $\cdots$ Pt interactions are detected in either $(-)-\mathbf{2}$ or $(-)-\mathbf{3}$. The dimers in $(-)-\mathbf{2}$ are aligned alternately into a one-dimensional head-to-tail chain through weak $\pi-\pi$ contacts along the $a$-axis (Figure 2). However, any intermolecular interactions are not found to connect the neighboring dimers in (-)-3, and the dimeric pairs are separated (Figure 2).

### 2.3. Spectroscopic Properties

The solution spectroscopic properties of all the complexes are shown in Figure 3. Intense absorptions ( $\varepsilon \approx 10^{4} \mathrm{~L} \cdot \mathrm{~mol}^{-1} \cdot \mathrm{~cm}^{-1}$ ) below 350 nm are ascribed to intraligand ${ }^{1} \pi, \pi^{*}$ transitions, and several moderate absorption bands ( $\varepsilon>10^{3} \mathrm{~L} \cdot \mathrm{~mol}^{-1} \cdot \mathrm{~cm}^{-1}$ ) in the low-energy region are attributed to mixed charge transfer transitions of ${ }^{1}$ MLCT (metal-to-ligand charge transfer) $/{ }^{1}$ ILCT (intraligand charge transfer) [7-10,19]. In comparison to isocyanide $\mathrm{Pt}(\mathrm{II})$ derivatives ((-)-1 and (-)-2), the low energy absorption of acetylide-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes $((-)-3$ and ( - )-4) with the same 5,6-membered bis(metallacycle) tail up to a longer
wavelength. For 5,6-membered bis(metallacyclic) $\operatorname{Pt}$ (II) complexes with the same auxiliary ligand, $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ derivatives $((-)-2$ and $(-)-4)$ show a lower energy absorption relative to those $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$-coordinated complexes $((-)-\mathbf{1}$ and $(-)$-3). The low energy absorptions of all complexes are concentration-independent and remain unchanged with increasing concentration (Figures S16-S19), suggesting the absence of aggregated states formed through $\mathrm{Pt} \cdots \mathrm{Pt}$ interactions in concentrated solution. The solvent influence on absorption has also been studied. The low energy absorption bands provide a slightly hypsochromic shift with the increased polarity of the solvents (Figures S20-S23), confirming the charge transfer (CT) character $[25,26]$. The chiral characteristics of all complexes have been determined through ECD (electronic circular dichroism) spectra (Figures S24-S27). Mirror-symmetric profiles can be detected for enantiomers. Positive Cotton effects below 350 nm that originate from chiral pinene ligands are observed for $(-)-\mathbf{1},(-)-\mathbf{2},(-)-3$, and $(-)-4$. In addition, weak Cotton effects in the low-energy region are exhibited [19]. Chiral environments around the central Pt nucleus are insignificant due to the nearly square-planar geometry of 5,6-membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes.

Figure 2. Crystal packings of (-)-2 and (-)-3.

Figure 3. Absorption and emission spectra ( $\lambda_{\text {ex }}=420 \mathrm{~nm}$ ) of all complexes in $\mathrm{CH}_{2} \mathrm{Cl}_{2}\left(5 \times 10^{-5} \mathrm{~mol} \cdot \mathrm{~L}^{-1}\right)$ at RT.

The $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solutions of $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$-coordinated $\mathrm{Pt}(\mathrm{II})$ derivatives ( - )-1 and ( - )-3 emit in the green-yellow region at RT, while the solutions of $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes $(-)-\mathbf{2}$ and $(-)-4$ emit orange light (Figure 3). Both complexes ( - )-1 and ( - )-3 display a vibronically structured emission with $\lambda_{\max }$ at 493 and 511 nm and shoulders at 528 and 541 nm , respectively (Figure 3 and Table 2). In contrast, a nearly structureless band in the orange region with lower energy emission peaks at 578 and 595 nm is perceived for complexes (-)-2 and ( - )-4, respectively. Acetylide-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes have a lower energy emission in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution than those isocyanide-coordinated ones ( $\Delta \lambda=\mathrm{ca}$. 20 nm ) (Figure 3 and Table 2), which is consistent with their absorption spectra. In addition to this, the emission spectra of $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ derivatives show a lower energy emission maximum relative to $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$-coordinated complexes with the same auxiliary ligand ( $\Delta \lambda=\mathrm{ca} .80 \mathrm{~nm}$ ) (Figure 3 and Table 2). The difference between cyclometalated $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ and $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ ligands exerts a more remarkable effect on the emission than the auxiliary ligands acetylide and isocyanide. The emission dependences on concentration and solvent are insignificant (Figures S16-S23). When changing from toluene to methanol, the solvatochromic emission shift is almost less than 10 nm , and the emission profiles stay the same with increasing concentration.

Table 2. Luminescent data in different states at RT and 77 K .

| Complexes | Medium | $\lambda_{\text {em }}(\mathrm{nm})$ | $\tau_{\text {em }}(\mu \mathrm{s})$ | $\Phi_{\text {em }}(\%)$ |
| :---: | :---: | :---: | :---: | :---: |
| $(-)-\mathbf{1}$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution (RT) | 493 | 0.98 | 2.49 |
|  | Rigid glass (77 K) | 488 |  |  |
|  | Solid state (RT) | 531 | 1.98 | 4.76 |
| $(-)-2$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution (RT) | 578 | 1.03 | 0.73 |
|  | Rigid glass (77 K) | 556 |  |  |
|  | Solid state (RT) | 597 | 2.82 | 3.33 |
| $(-)-3$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution (RT) | 511 | 1.81 | 1.72 |
|  | Rigid glass (77 K) | 503 |  |  |
|  | Solid state (RT) | 555 | 3.01 | 7.47 |
| $(-)-4$ | $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution (RT) | 595 | 1.07 | 0.80 |
|  | Rigid glass (77 K) | 561 |  |  |
|  | Solid state (RT) | 628 | 3.17 | 2.61 |

All the complexes provide a more structured and narrower emission band in frozen glass at 77 K than in a fluid at RT (Figure S28). The complexes ((-)-1 and (-)-3) with $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ skeleton show a negligible rigidochromic effect with the value of emission maximum shift $5-8 \mathrm{~nm}$. In contrast, the rigidochromic shift of derivatives ((-)-2 and (-)-4) with $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ parent ligand is evident with a $22-34 \mathrm{~nm}$ difference between the emission maximum in the fluid and the rigid glass. According to the reported investigations on 5,6-membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes, not only the cyclometalated parent ligand $\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right.$ and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ ) and the auxiliary ligand (isocyanide and acetylide) could affect the emission of complexes but also the conjugation degree of the 5,6-membered bis(metallacycle) through the amino N atom exerts a considerable influence on the emission $[8,19]$. The emissive state of all complexes can be assigned to a ligand-centered (LC) triplet transition $\left({ }^{3} \pi, \pi\right)$ with some CT transitions [7-9,19]. The low energy emissions ( 578 and 595 nm ) have more CT character than the high-energy ones (493 and 511 nm ) [8,19]. For complexes ( - )-2 and $(-)-4$, the geometric change to maximize conjugation of the 5,6-membered bis(metallacycle) through the amino N atom is unfavorable in the rigid matrix. Hence, the emission state has more $\mathrm{LC}^{3} \pi, \pi$ characteristic in the rigid glass at 77 K , showing a high energy emission.

The solids of all complexes are emissive from the green-yellow to orange regions at RT (Figure 4 and Table 2). The emission spectra of $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$-coordinated complexes are more structured and show a higher energy emission maximum than the ones of $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ coordinated derivatives. At 77 K , the emission profiles become highly structured and narrow. The solids show higher emission quantum efficiencies ( $\Phi_{\mathrm{em}}$ ) than the solutions (Table 2). The $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated derivatives with isocyanide and acetylide could not
form aggregates under external stress like chloride precursors, and the mechanochromic luminescence phenomenon is not realized for $(-)-2$ and $(-)-4$ [19].

Figure 4. Solid-state emission spectra ( $\lambda_{\mathrm{ex}}=420 \mathrm{~nm}$ ) of all complexes at RT (solid line) and at 77 K (dotted line).

### 2.4. Theoretical Investigation

Time-dependent density functional theory (TD-DFT) calculations have been performed to explore the origin of the transitions [27]. As revealed in Figure 5 and Table S3, the nature of $S_{0} \rightarrow S_{1}$ transition of all complexes mainly derive from HOMO (the highest occupied molecular orbital) $\rightarrow$ LUMO (the lowest unoccupied molecular orbital) with the overwhelming contribution of over $90 \%$. Also, the $S_{0} \rightarrow S_{1}$ transition of complex ( - )-1 involves some composition of HOMO-1 $\rightarrow$ LUMO $(7.0 \%)$. Based on molecular orbital (MO) patterns and orbital composition analysis (Figure 5 and Table S3), the HOMO of complexes ( - )-1 and $(-)-2$ is mainly delocalized on Ring B, Ring C, and their bridging atom amino N with a total contribution of over $80 \%$. Their LUMO concentrates on phenyl-pyridine or dipyridine moiety (Ring A and Ring B). In addition, the central Pt atom in $(-)-\mathbf{1}$ and $(-)-\mathbf{2}$ contributes little to HOMO and LUMO.

For acetylide-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes ( - )-3 and ( - )-4, the HOMO primarily comes from Pt nucleus and phenylacetylene with a total contribution of over $60 \%$, and the fragments Ring B and Ring C also contribute some to the HOMO (Figure 5 and Table S3). Similar to the LUMO distribution of $(-)-\mathbf{1}$ and $(-)-\mathbf{2}$, the phenyl-pyridine or dipyridine moiety (Ring A and Ring B) gives a dominant contribution ( $>75 \%$ ) to the LUMO of ( - )-3 and (-)-4. Therefore, a mixture of ${ }^{1}$ ILCT $\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right.$ or $\left.\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right),{ }^{1}$ MLCT (from $\mathrm{Pt}(\mathrm{II})$ atom to $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ or $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ ) and ${ }^{1}$ LLCT (from phenyl isocyanide or phenylacetylene to $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ or $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ ) transitions should be responsible for the lowest energy absorption band in the UV-vis spectra of all complexes. Furthermore, more ${ }^{1} \mathrm{MLCT}$ and ${ }^{1}$ LLCT components are involved in acetylide-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes $(-)-3$ and $(-)-4$, showing a calculated longer absorption wavelength than $(-)-1$ and $(-)-2$ with the same cyclometalated ligand (Table S3), which accords with the ones observed in the experiment (Figure 3).

To gain an insightful understanding of emission, natural transition orbital (NTO) analysis has been accomplished to examine the $S_{0} \rightarrow T_{1}$ excitation based on optimized $T_{1}$ geometries (Figure 6 and Table S4) $[19,28]$. The hole $(H)$ orbital of $(-)-\mathbf{1}$ is mainly resident in the phenyl-pyridine or dipyridine moiety (Ring A and Ring B), and the one of ( - )-2 is spread over the whole $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ ligand (amino N atom, Ring A, Ring B, and Ring C). For complexes (-)-3 and (-)-4, the central Pt atom holds a considerable distribution (18.16\%
and $11.07 \%$ ) of the H orbital in addition to the contribution of the $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ or $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ parent. All complexes' particle ( P ) orbitals are mainly distributed on the phenyl-pyridine or dipyridine moiety (Ring A and Ring B), with a predominant contribution of over $85 \%$. Hence, the luminescence of $(-)-\mathbf{1}$ and $(-)-\mathbf{2}$ can be mainly assigned as a ligand-centered (LC) triplet state $\left({ }^{3} \pi, \pi^{*}\right)$ with minor CT character. In contrast, the phosphorescence of $(-)-3$ and (-)-4 originates from a mixture of ${ }^{3} \pi, \pi^{*}$ and ${ }^{3} \mathrm{MLCT}$ (from Pt (II) atom to $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ or $\mathrm{N}^{\wedge} \mathrm{N}{ }^{*} \mathrm{C}$ ) emissive states.

Figure 5. Molecular orbital (MO) patterns of all complexes on the basis of their optimized $\mathrm{S}_{0}$ geometries.

Figure 6. Natural transition orbital patterns for $S_{0}-T_{1}$ excitation for all complexes on the basis of their optimized $\mathrm{T}_{1}$ geometries.

### 2.5. Cytotoxicity

All the prepared 5,6-membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes, including chloride precursors, were evaluated for their cytotoxicity against human cancer cell lines K562, SGC7901, BEL-7402, A549, and HeLa with cisplatin as the positive control [29,30]. From Table 3, the obtained half-inhibitory concentration $\left(\mathrm{IC}_{50}\right)$ values range from 0.47 to $8.85 \mu \mathrm{M}$. $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ coordinated $\mathrm{Pt}(\mathrm{II})$ complex $(-)-2$ with isocyanide displays significant cytotoxicity against the above five human cancer lines, which is better than that of cisplatin and comparable to those of pincer-type platinum(II) complexes $\mathrm{Pt}^{\mathrm{II}}\left(\mathrm{NCN}^{\prime}\right) \mathrm{Cl}, \mathrm{Pt}^{\mathrm{II}}\left(\mathrm{CNN}^{\prime}\right) \mathrm{Cl},\left(\mathrm{CNN}^{\prime}\right) \mathrm{Pt}^{\mathrm{II}}(\mathrm{C} \equiv \mathrm{CCH} 2 \mathrm{R})$, $\left(\mathrm{CNN}^{\prime}\right) \mathrm{Pt}^{\mathrm{II}}(\mathrm{C} \equiv \mathrm{NL})^{+}$and $[\mathrm{Pt}(\operatorname{trpy})(\mathrm{NHC})]^{2+}$ containing N -heterocyclic carbene (NHC) ligand [31-36]. All complexes with $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ ligands provide a cytotoxic activity, so $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ 5,6-membered bis(metallacycle) may be important for high cytotoxicity [32]. In addition, it can be inferred that the introduction of isocyanide and alkynyl may improve the cytotoxic effect by comparing the cytotoxicity results of $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right) \mathrm{Cl},(-)-2$ and $(-)-4$. UV-vis spectroscopy has also checked the stability of the complexes obtained in DMSO and DMSO-PBS media [37]. The absorbance at 424 nm of the DMSO-PBS and DMSO solutions of ( - )-2 decreases by ca. $30 \%$ and $10 \%$ at $37^{\circ} \mathrm{C}$ over 5 days, respectively (Figures S29-S34). However, the low energy absorptions of the DMSO-PBS solutions of other complexes dramatically decrease by $50-80 \%$.

Table 3. The cytotoxicity results of 5,6 -membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes $(\mu \mathrm{M})$ and reported pincer-type $\mathrm{Pt}(\mathrm{II})$ complexes.

### 2.6. Cell Imaging

Given the intriguing luminescence properties of 5,6-membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes, we tentatively explore their applications in cell imaging. The cultured HeLa cells were inoculated in glass-bottom cell culture dishes. After overnight culture, the cells were stained with $10 \mu \mathrm{~mol} / \mathrm{L}$ phosphorescent Pt complexes in a DMSO/DMEM mixture (5/95) for 15 min . After the removal of extracellular fluorescent dyes through washing with PBS buffer, the cell samples were imaged using confocal laser scanning fluorescence microscopy in blue, green, and red channels $[38,39]$. As shown in Figure 7, the chloride precursor $\operatorname{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}$ can efficiently permeate cells, showing bright blue luminescence and bright green emission, and the image in the red channel is not satisfactory enough.

Other luminescent $\mathrm{Pt}(\mathrm{II})$ complexes can also rapidly permeate cells. However, the image performances are inferior to $\operatorname{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}$. It can be found that the luminescent $\operatorname{Pt}(\mathrm{II})$ complexes mainly distribute in cell membranes and are hard to stain the intracellular substances [38-40]. Complexes (-)-1, (-)-2, and (-)-3 show excellent photostability in the DMSO/DMEM mixture (5/95) and can retain $97 \%$ of the emission intensity after 40 min irradiation (Figure S35) [41]. However, nearly $10 \%$ of chloride precursors $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}$, $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right) \mathrm{Cl}$, and complex $(-)-4$ have decayed upon 40 min continuous excitation.

Figure 7. Confocal images of HeLa cells stained with 5,6-membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes, $\mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}(\mathbf{A}-\mathrm{D}), \mathrm{Pt}\left(\mathrm{N}^{\wedge} \mathrm{N}^{\prime} * \mathrm{C}\right) \mathrm{Cl}(\mathrm{E}-\mathrm{H}),(-)-\mathbf{1}(\mathbf{I}-\mathrm{L}),(-)-\mathbf{2}(\mathbf{M}-\mathbf{P}),(-)-\mathbf{3}(\mathbf{Q}-\mathbf{T})$, and $(-)-4$ ( $\mathbf{U}-\mathbf{X}$ ).

## 3. Experimental

### 3.1. General Methods

All reagents were purchased from commercial suppliers and used as received. Highresolution ESI (HR-ESI) mass spectrometry spectra were acquired on Thermo Scientific (Waltham, MA, USA) Q Exactive Mass, Thermo Scientific Q Exactive Focus, and Aglient (Santa Clara, CA, USA) 7250 \& JEOL-JMS-T100LP AccuTOF (Tokyo, Japan) Spectrometer. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra were obtained on Bruker (Mannheim, Germany) DRX-400 spectrometer. Coupling constants are provided in hertz. UV-vis spectra were measured on a UV-3600 spectrophotometer. Photoluminescence (PL) spectra were measured by a Hitachi (Tokyo, Japan) F-4600 PL spectrophotometer ( $\lambda_{\mathrm{ex}}=420 \mathrm{~nm}$ ). Emission quantum yields ( $\lambda_{\mathrm{ex}}=420 \mathrm{~nm}$ ) and lifetimes were measured on a HORIBA JY (Kyoto, Japan) system. The circular dichroism (CD) spectra in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution were recorded on a Jasco (Tokyo, Japan) J-810 spectropolarimeter at a scan rate of $100 \mathrm{~nm} \cdot \mathrm{~min}^{-1}$ and 1 nm resolution at room temperature (using 10 mm quartz cell for the concentration of $5 \times 10^{-5} \mathrm{~mol} \cdot \mathrm{~L}^{-1}$, bandwidth $=1 \mathrm{~nm}$, response $=1 \mathrm{~s}$, accumulations = 3). Images of cells were obtained using a Nikon (Tokyo, Japan) A1 confocal laser scanning microscope.

### 3.2. Synthetic Procedures

### 3.2.1. Preparation of Chloride Precursors

$\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$-coordinated $\mathrm{Pt}(\mathrm{II})$ chloride precursors were prepared according to our reported literature [19].

### 3.2.2. Preparation of $(-)-\mathbf{1}$

An equivalent of 2,6-dimethylphenyl isocyanide ( $18.3 \mathrm{mg}, 0.14 \mathrm{mmol}$ ) dissolved in dichloromethane was added dropwise into a vigorously stirred dichloromethane solution of $\mathrm{Pt}\left((-)-\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}(100 \mathrm{mg}, 0.14 \mathrm{mmol})$ pre-covered by an aqueous solution of excess AgOTf. After stirring at RT for 1 h , the dichloromethane solution was separated, and the aqueous phase was extracted with dichloromethane ( $20 \mathrm{~mL} \times 3$ ). The organic phase was washed with brine water and then dried over anhydrous $\mathrm{Na}_{2} \mathrm{SO}_{4}$. After removing the solvent in vacuo, the final product was obtained as green-yellow powder. Yield: $80 \%$. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$-d1): $\delta 9.21\left[\mathrm{dd}, J_{1}=6.4 \mathrm{~Hz}, J_{1}=1.2 \mathrm{~Hz}, 1 \mathrm{H}\right], 8.47[\mathrm{~s}, 1 \mathrm{H}]$, $7.72[\mathrm{t}, J=7.6 \mathrm{~Hz}, 3 \mathrm{H}], 7.62-7.67[\mathrm{~m}, 2 \mathrm{H}], 7.45[\mathrm{~d}, J=7.2 \mathrm{~Hz}, 1 \mathrm{H}], 7.41[\mathrm{t}, J=7.6 \mathrm{~Hz}, 1 \mathrm{H}]$, $7.33[\mathrm{~d}, J=7.2 \mathrm{~Hz}, 2 \mathrm{H}], 7.28[\mathrm{t}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}], 7.13[\mathrm{t}, J=7.6 \mathrm{~Hz}, 1 \mathrm{H}], 6.84\left[\mathrm{td}, J_{1}=6.8 \mathrm{~Hz}\right.$, $\left.J_{2}=1.2 \mathrm{~Hz}, 1 \mathrm{H}\right], 6.67[\mathrm{~d}, J=9.2 \mathrm{~Hz}, 1 \mathrm{H}], 6.40[\mathrm{~d}, J=8.0 \mathrm{~Hz}, 1 \mathrm{H}], 3.18[\mathrm{~s}, 2 \mathrm{H}], 2.77-2.81[\mathrm{~m}$ $2 \mathrm{H}], 2.59[\mathrm{~s}, 6 \mathrm{H}], 2.40[\mathrm{~m}, 1 \mathrm{H}], 1.45[\mathrm{~s}, 3 \mathrm{H}], 1.30[\mathrm{~d}, J=9.6 \mathrm{~Hz}, 1 \mathrm{H}], 0.73[\mathrm{~s}, 3 \mathrm{H}] .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$-d1): $\delta 165.1,157.9,151.2,150.5,147.9,147.8,145.0,142.0,139.4,138.5$, $136.2,132.3,131.5,130.4,130.3,129.4,127.9,123.0,120.7,120.3,119.9,118.2,117.0,45.1,40.0$, 39.9, 33.8, 32.0, 26.2, 22.0, 19.6. HRMS (ESI) $(m / z)$ : [M] ${ }^{+}$calcd for $\mathrm{C}_{38} \mathrm{H}_{35} \mathrm{~N}_{4} \mathrm{Pt}^{+}, 742.2504$; found, 742.2498. Anal. Calcd for $\mathrm{C}_{39} \mathrm{H}_{35} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{3} \mathrm{PtS}((-)-1): \mathrm{C}, 52.52 ; \mathrm{H}, 3.96 ; \mathrm{N}, 6.28 ; \mathrm{O}$, $5.38 \%$. Found: C, 52.51 ; H, 3.95; N, 6.29; O, $5.38 \%$.

### 3.2.3. Preparation of $(-)-2$

The preparation procedure of $(-)-2$ is the same as the one of $(-)-1$, we just changed the $\mathrm{Pt}(\mathrm{II})$ chloride precursor to $\mathrm{Pt}\left((-)-\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right) \mathrm{Cl}$. The final product of $(-)-2$ was also obtained as yellow powder. Yield: $90 \%$. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}-\mathrm{d} 1$ ): $\delta 8.73$ [s, 1H], $8.49[\mathrm{~s}, 1 \mathrm{H}], 8.44[\mathrm{~d}, J=7.6 \mathrm{~Hz}, 1 \mathrm{H}], 8.19\left[\mathrm{dd}, J_{1}=7.6 \mathrm{~Hz}, J_{2}=1.6 \mathrm{~Hz}, 1 \mathrm{H}\right], 8.00[\mathrm{dd}$, $\left.J_{1}=9.2 \mathrm{~Hz}, J_{1}=7.6 \mathrm{~Hz}, 1 \mathrm{H}\right], 7.74[\mathrm{t}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}], 7.66\left[\mathrm{tt}, J_{1}=7.6 \mathrm{~Hz}, J_{2}=1.2 \mathrm{~Hz}, 1 \mathrm{H}\right]$, $7.43[\mathrm{t}, J=7.6 \mathrm{~Hz}, 1 \mathrm{H}], 7.36[\mathrm{~d}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}], 7.31[\mathrm{~d}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}], 7.11\left[\mathrm{td}, J_{1}=7.6 \mathrm{~Hz}\right.$, $\left.J_{2}=1.6 \mathrm{~Hz}, 1 \mathrm{H}\right], 6.91[\mathrm{~d}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}], 6.68\left[\mathrm{dd}, J_{1}=8.8 \mathrm{~Hz}, J_{2}=1.2 \mathrm{~Hz}, 1 \mathrm{H}\right], 3.34$ [dd, $\left.J_{1}=7.6 \mathrm{~Hz}, J_{2}=2.0 \mathrm{~Hz}, 2 \mathrm{H}\right], 2.88[\mathrm{t}, J=5.6 \mathrm{~Hz}, 1 \mathrm{H}], 2.77-2.83[\mathrm{~m}, 1 \mathrm{H}], 2.64[\mathrm{~s}, 6 \mathrm{H}], 2.44[\mathrm{~m}$, $1 \mathrm{H}], 1.45[\mathrm{~s}, 3 \mathrm{H}], 1.32[\mathrm{~d}, \mathrm{~J}=10.0 \mathrm{~Hz}, 1 \mathrm{H}], 0.72[\mathrm{~s}, 3 \mathrm{H}] .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}-\mathrm{d} 1$ ): $\delta$ $154.9,153.9,151.4,148.8,147.8,144.1,142.8,139.3,138.6,135.9,131.9,130.8,130.2,129.9$, 129.0, 126.4, 124.6, 123.2, 119.8, 118.8, 117.2, 115.4, 45.1, 39.7, 39.4, 33.6, 31.4, 25.9, 21.7, 19.2. HRMS (ESI) $(\mathrm{m} / \mathrm{z})$ : $[\mathrm{M}]^{+}$calcd for $\mathrm{C}_{38} \mathrm{H}_{35} \mathrm{~N}_{4} \mathrm{Pt}^{+}, 742.2504$; found, 742.2491. Anal. Calcd
for $\mathrm{C}_{39} \mathrm{H}_{35} \mathrm{~F}_{3} \mathrm{~N}_{4} \mathrm{O}_{3} \operatorname{PtS}((-)-2)$ : C, 52.52; H, 3.96; N, 6.28; O, 5.38\%. Found: C, 52.51; H, 3.96; N, 6.28; O, $5.37 \%$.

### 3.2.4. Preparation of ( - )-3

A methanol solution of phenylacetylene ( $20.5 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) and sodium hydroxide ( $8 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) was stirred for 30 min at RT. Then, the chloride precursor $\mathrm{Pt}((-)$ $\left.\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}\right) \mathrm{Cl}(97 \mathrm{mg}, 0.15 \mathrm{mmol})$ was added to the above solution, reacting for a further 24 h . The solvent was removed in vacuo, and the solid was washed with methanol several times $(20 \mathrm{~mL} \times 3)$. The final product, a yellow powder, was obtained after recrystallization in a mixed methanol/chloromethane solution. Yield: $85 \%$. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}$-d2): $\delta 10.57\left[\mathrm{dd}, J_{1}=6.4 \mathrm{~Hz}, J_{2}=1.6 \mathrm{~Hz}, 1 \mathrm{H}\right], 9.67[\mathrm{~s}, 1 \mathrm{H}], 7.68[\mathrm{t}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}], 7.58[\mathrm{t}$, $J=7.6 \mathrm{~Hz}, 1 \mathrm{H}], 7.53[\mathrm{~s}, 1 \mathrm{H}], 7.49[\mathrm{~d}, J=7.6 \mathrm{~Hz}, 2 \mathrm{H}], 7.44\left[\mathrm{tt}, J_{1}=7.6 \mathrm{~Hz}, J_{2}=2.0 \mathrm{~Hz}, 1 \mathrm{H}\right]$, $7.33[\mathrm{~d}, J=7.2 \mathrm{~Hz}, 2 \mathrm{H}], 7.29[\mathrm{~m}, 3 \mathrm{H}], 7.19\left[\mathrm{tt}, J_{1}=7.6 \mathrm{~Hz}, J_{2}=2.0 \mathrm{~Hz}, 1 \mathrm{H}\right], 6.95[\mathrm{t}, \mathrm{J}=7.6 \mathrm{~Hz}$, $1 \mathrm{H}], 6.56\left[\mathrm{td}, J_{1}=6.4 \mathrm{~Hz}, J_{2}=1.2 \mathrm{~Hz}, 1 \mathrm{H}\right], 6.43[\mathrm{~d}, J=9.2 \mathrm{~Hz}, 1 \mathrm{H}], 6.20[\mathrm{~d}, J=8.0 \mathrm{~Hz}, 1 \mathrm{H}]$, $3.07[\mathrm{~d}, J=2.4 \mathrm{~Hz}, 2 \mathrm{H}], 2.89[\mathrm{t}, J=5.6 \mathrm{~Hz}, 1 \mathrm{H}], 2.71-2.76[\mathrm{~m}, 1 \mathrm{H}], 2.33[\mathrm{~m}, 1 \mathrm{H}], 1.42[\mathrm{~s}, 3 \mathrm{H}]$, $1.27[\mathrm{~d}, J=9.2 \mathrm{~Hz}, 1 \mathrm{H}], 0.73[\mathrm{~s}, 3 \mathrm{H}] .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CD}_{2} \mathrm{Cl}_{2}-\mathrm{d} 2$ ): $\delta 166.1,159.2,150.1$, 149.9, 147.3, 147.1, 143.3, 143.2, 142.0, 139.9, 135.9, 135.5, 131.2, 130.4, 128.7, 128.6, 127.8, 124.9, 123.7, 118.3, 118.0, 117.7, 116.1, 114.4, 107.2, 44.5, 39.7, 39.2, 33.7, 31.6, 25.7, 21.3. HRMS (ESI) $(m / z)$ : [M] ${ }^{+}$calcd for $\mathrm{C}_{37} \mathrm{H}_{31} \mathrm{~N}_{3} \mathrm{Pt}^{+}, 712.2166$; found, 712.2105. Anal. Calcd for $\mathrm{C}_{37} \mathrm{H}_{31} \mathrm{~N}_{3} \mathrm{Pt}((-)-3)$ : C, $62.35 ; \mathrm{H}, 4.38 ; \mathrm{N}, 5.90 \%$. Found: C, $62.36 ; \mathrm{H}, 4.39 ; \mathrm{N}, 5.90 \%$.

### 3.2.5. Preparation of $(-)-4$

A 50 mL dry flask was charged with $\operatorname{Pt}\left((-)-\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}\right) \mathrm{Cl}(97 \mathrm{mg}, 0.15 \mathrm{mmol})$, phenylacetylene ( $49.6 \mu \mathrm{~L}, 0.45 \mathrm{mmol}$ ), $\mathrm{Et}_{3} \mathrm{~N}(1.40 \mathrm{~mL})$, and $\mathrm{CuI}(2.1 \mathrm{mg})$ in chloromethane solution ( 15 mL ). In the absence of light, the mixture was stirred at RT under argon for 24 h . The solvent was evaporated in vacuo, and the residue was purified by flash chromatography on the $\mathrm{Al}_{2} \mathrm{O}_{3}$ column with $\mathrm{PE} / \mathrm{EA}(3 / 1, v / v)$ as eluent to yield an orange powder. Yield: $70 \% .{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$-d1): $\delta 9.63[\mathrm{~s}, 1 \mathrm{H}], 9.17$ [dd, $J_{1}=6.4 \mathrm{~Hz}$, $\left.J_{2}=3.2 \mathrm{~Hz}, 1 \mathrm{H}\right], 7.85[\mathrm{~s}, 1 \mathrm{H}], 7.56-7.66[\mathrm{~m}, 5 \mathrm{H}], 7.55[\mathrm{t}, J=7.6 \mathrm{~Hz}, 1 \mathrm{H}], 7.45[\mathrm{~d}, J=$ $7.2 \mathrm{~Hz}, 1 \mathrm{H}], 7.35[\mathrm{~d}, J=7.2 \mathrm{~Hz}, 2 \mathrm{H}], 7.30[\mathrm{t}, J=7.2 \mathrm{~Hz}, 2 \mathrm{H}], 7.18[\mathrm{t}, J=7.2 \mathrm{~Hz}, 1 \mathrm{H}], 6.89$ [dd, $\left.J_{1}=7.0 \mathrm{~Hz}, J_{2}=3.6 \mathrm{~Hz}, 2 \mathrm{H}\right], 6.68[\mathrm{~d}, J=9.2 \mathrm{~Hz}, 1 \mathrm{H}], 6.43\left[\mathrm{dd}, J_{1}=6.4 \mathrm{~Hz}, J_{2}=3.6 \mathrm{~Hz}, 1 \mathrm{H}\right]$, $3.08[\mathrm{~d}, \mathrm{~J}=10.0 \mathrm{~Hz}, 2 \mathrm{H}], 3.00[\mathrm{t}, J=5.6 \mathrm{~Hz}, 1 \mathrm{H}], 2.75-2.80[\mathrm{~m}, 1 \mathrm{H}], 2.37$ [m, 1H], 1.45 [s, $3 \mathrm{H}], 1.28[\mathrm{~d}, \mathrm{~J}=9.6 \mathrm{~Hz}, 1 \mathrm{H}], 0.69[\mathrm{~s}, 3 \mathrm{H}] .{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}-\mathrm{d} 1$ ): $\delta 155.1,154.3$, $148.9,146.6,146.0,145.0,144.2,140.1,134.5,131.6,131.1,130.8,129.4,128.7,127.9,124.9$, 123.7, 121.9, 121.3, 120.6, 118.2, 117.6, 113.1, 100.9, 44.9, 39.8, 39.3, 33.4, 31.5, 25.8, 21.5. ### 3.3. Single-Crystal X-ray Structure Determination

Single-crystal X-ray diffraction measurements were performed on a Bruker SMART APEX CCD and Rigaku (Tokyo, Japan) XtaLAB Synergy R. Intensities were collected with graphite monochromatized Mo $\mathrm{K} \alpha$ radiation $(\lambda=0.71073 \AA$ ) operating at 50 kV and 30 mA using $\omega / 2 \theta$ scan mode. The data reduction was performed with the Bruker SAINT package [42]. Absorption corrections were performed using the SADABS program [43]. The structures were solved by direct methods and refined on $F^{2}$ by full-matrix least-squares using SHELXL-2018/3 (Sheldrick, 2018) with anisotropic displacement parameters for all non-hydrogen atoms in the two structures. Hydrogen atoms bonded to carbon atoms were placed in calculated positions and refined as riding mode, with $\mathrm{C}-\mathrm{H}=0.93 \AA$ (methane) or $0.96 \AA$ (methyl) and $\operatorname{Uiso}(H)=1.2 \operatorname{Ueq}\left(\mathrm{C}_{\text {methane }}\right)$ or $\operatorname{Uiso}(\mathrm{H})=1.5 \mathrm{Ueq}\left(\mathrm{C}_{\text {methyl }}\right)$. All computations were carried out using the SHELXL-2018/3 program package [44]. CCDC numbers 2279411-2279412 contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via https:/ /www.ccdc.cam.ac.uk/structures / (accessed on 5 July 2023) or by e-mailing data_request@ccdc.cam.ac.uk, or by contacting

The Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB2 1EZ, UK; fax: $+44(0) 1223-336033$.

### 3.4. Calculation Methods

The crystal structures of (-)-2 and (-)-3 were used as starting geometries, and calculations were performed with the Gaussian 09 program [45]. Geometry optimizations of ground states were simulated with density functional theory (DFT) at the hybrid functional PBE1PBE-D3/LANL2DZ (Pt) and PBE1PBE-D3/6-31g(d,p) (H, C, N) levels using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ as solvent. The solvent effect is based on the polarizable continuum model (PCM). The optimized structures were used to calculate the lowest singlet electronic transition using the time-dependent density functional theory (TDDFT) method. The geometry of the first triplet state $\left(\mathrm{T}_{1}\right)$ was optimized, and the analysis of the natural transition orbital (NTO) was carried out for the excitation of $\mathrm{S}_{0} \rightarrow \mathrm{~T}_{1}[28,46]$. Mulliken population analysis (MPA) was utilized to obtain the electron density distribution of each atom in the specific molecular orbital of the $\mathrm{Pt}(\mathrm{II})$ complexes using the Multiwfn program [47].

### 3.5. Cytotoxicity

The cytotoxic activities of obtained 5,6-membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes were assessed against K562 (human leukemia cell line), SGC-7901 (human gastric carcinoma cells line), BEL-7402 (human hepatocellular carcinoma cell line), A549 (human non-small cell lung cancer cell line), and HeLa (human cervical cancer cell line) by MTT assay [29,30]. Briefly, the logarithmic phase cells were cultured in RPMI 1640 medium supplemented with $10 \%$ fetal bovine serum, $100 \mathrm{IU} / \mathrm{mL}$ penicillin, and $100 \mathrm{mg} / \mathrm{mL}$ streptomycin under conditions of $37^{\circ} \mathrm{C}, 5 \% \mathrm{CO}_{2}$, and $90 \%$ humidity. These human tumor cell lines with a density of $5 \times 10^{4} \mathrm{unit} / \mathrm{mL}$ were seeded onto 96 -well plates and then, after 24 h of incubation, treated with different concentrations of the sample dissolved in DMSO, respectively, while cisplatin was used as the positive control and DMSO was used as the negative control. After 72 h of incubation, MTT was dissolved at $5 \mathrm{mg} / \mathrm{mL}$ in PBS and used essentially as previously described. Finally, the inhibition rates were calculated using OD mean values measured by the MK3 Microtiter plate reader at 490 nm , and the $\mathrm{IC}_{50}$ value expressed as the mean standard deviation was determined using the Bliss method.

## 4. Conclusions

In summary, we have synthesized four groups of enantiomeric $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ - and $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ coordinated $\mathrm{Pt}(\mathrm{II})$ complexes featuring a fused $5,6-$ membered bis(metallacycle). Their structures have been determined by NMR, HRMS, and single-crystal X-ray diffraction. Distorted square-planar coordination of the $\mathrm{Pt}(\mathrm{II})$ nucleus is observed for both isocyanideand acetylide-containing derivatives. The solution of all complexes is emissive in the greenyellow or orange regions, and acetylide-coordinated $\mathrm{Pt}(\mathrm{II})$ complexes show a lower energy emission than those isocyanide-coordinated ones with the same cyclometalated ligand ( $\Delta \lambda=$ ca. 20 nm in the solution). Furthermore, the difference between cyclometalated $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C}$ and $\mathrm{N}^{\wedge} \mathrm{C}^{*} \mathrm{~N}^{\prime}$ ligands induces a more significant effect ( $\Delta \lambda=\mathrm{ca} .80 \mathrm{~nm}$ in the solution) on the emission. The influence trend is also observed for the solid-state emission. The emissive state of all complexes can be attributed to a ligand-centered (LC) triplet transition $\left({ }^{3} \pi, \pi\right)$ with some CT transitions. Platinum(II) complex ( - )-2 coordinated with isocyanide displays high cytotoxicity against the above five human cancer lines K562, SGC7901, BEL-7402, A549, and HeLa. The existence of $\mathrm{N}^{\wedge} \mathrm{N}^{\prime *} \mathrm{C} 5,6$-membered bis(metallacycle) may be important for high cytotoxicity. All the complexes can efficiently permeate cells, mainly distributing in cell membranes and showing a clear cell outline. This research provides a reference for developing biologically active 5,6-membered bis(metallacyclic) $\mathrm{Pt}(\mathrm{II})$ complexes.
