

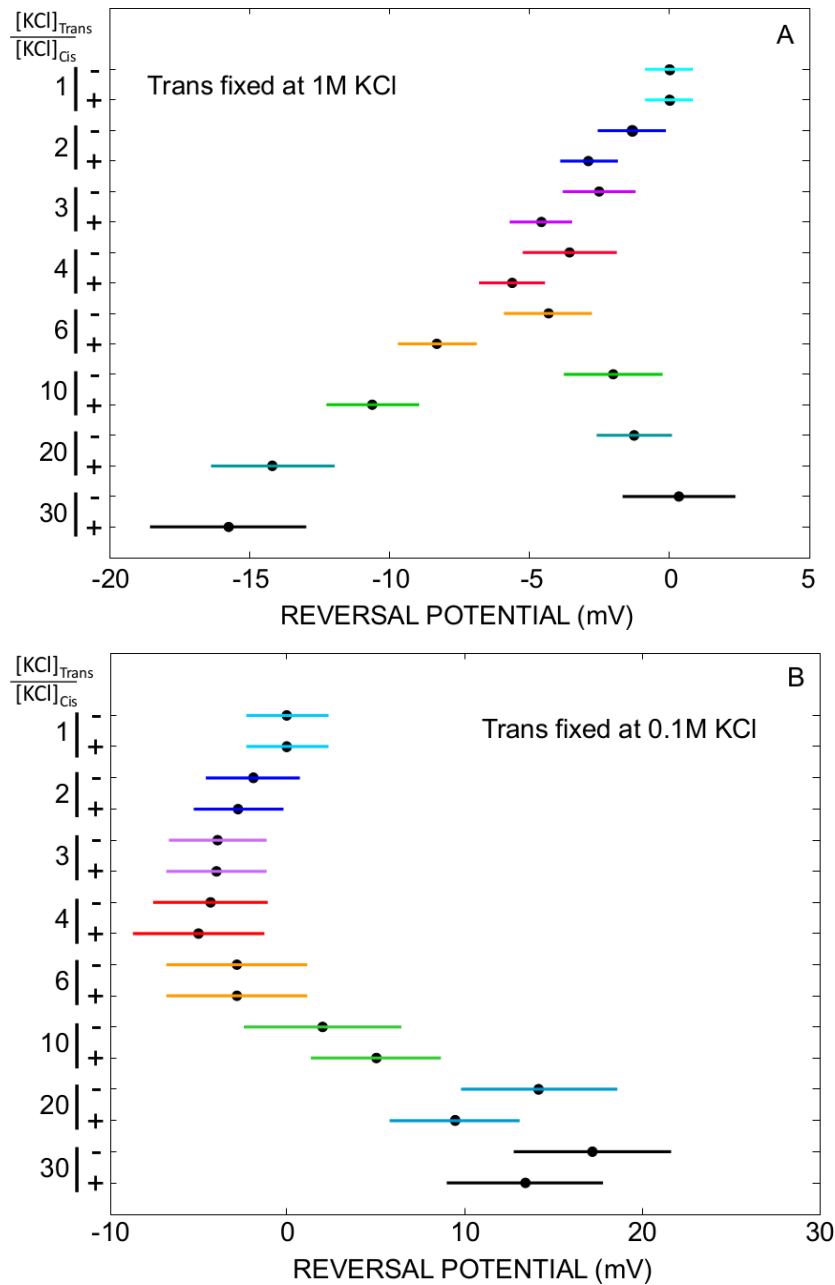

Figure S1 : Multiple pairwise comparison

We performed pairwise comparison to confirm that there are pairs of means that are significantly different in figure 2C and 2D. For each group, the horizontal line represents the 95% confidence ($p < 0.05$) interval for the true mean (black circle). Panel A: The data indicates that at high ionic strength (fixed Trans concentration 1M) there is a statistically significant effect of stigmasterol on the PcVDAC selectivity for KCl concentration ratio higher than 4. Panel B: The data indicates that at low ionic strength (fixed Trans concentration 0.1M) there is no statistically significant effect of stigmasterol on the PcVDAC selectivity for all KCl concentration ratio.
