

Supplementary Materials: Development of a Detection Algorithm for Use with Reflectance-Based, Real-Time Chemical Sensing

Anthony P. Malanoski, Brandy J. Johnson, Jeffrey S. Erickson and David A. Stenger

Multiplex Development Platform (PT3)

Two different sensor platforms were used in this work, each of which controlled and collected data from six different commercially produced RGB color-to-frequency breakout boards (model TCS3200-DB, Rocklin, CA, USA). Each platform consisted of a custom printed circuit board (PCB) to control the hardware, timing, data collection, and to regulate and distribute power. Other components include sample holders, software interface, and in the case of the PT5, a housing with fans to provide airflow over the samples.

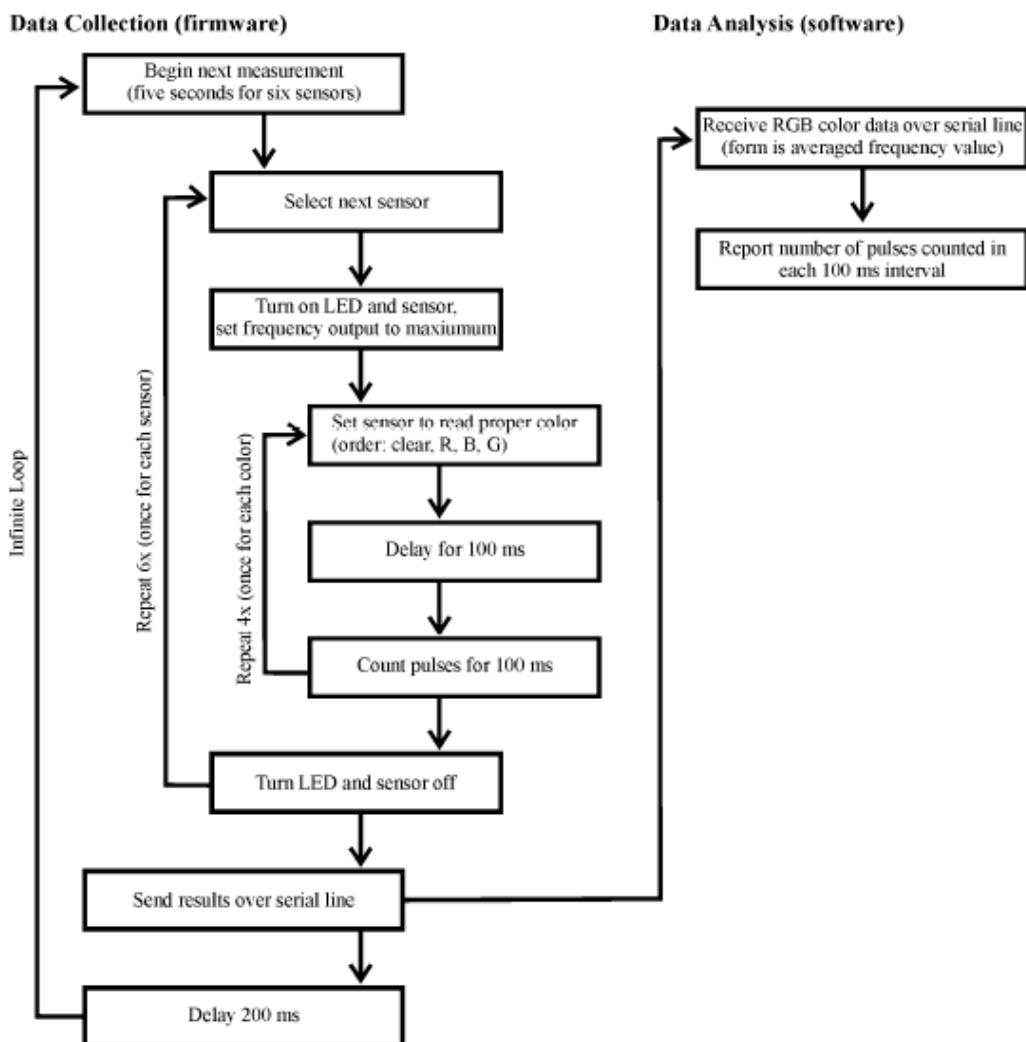

The first platform, labeled PT3, has been described previously (Johnson et al. (2014), doi:10.1088/0957-0233/25/9/095101). The PT3 uses flexible cables to connect six of the RGB sensors to a custom circuit board; the RGB sensors are mounted to in-house developed sample holders machined from chemically resistant Delrin plastic. The sample holders are designed to provide a working distance of one inch from sample to sensor using copper spring clips (Ted Pella, Redding, CA) to mount the indicators and are open at the bottom to allow vapor to interact with the targets (Figure S1). The Delrin bases are designed to serve as lids for 60 mm Petri dishes. Each RGB sensor has two white LEDs mounted at 45-degree angles to the indicator surface. When activated, each sensor pulses the LEDs for 800 ms, during which the red, green, blue, and clear channels are measured. Integration time for each channel is fixed at 100 ms. Each set of LEDs are on only during the 800 ms interval when the sample is being actively probed in order to minimize any photobleaching as well as power requirements. The six RGB sensors are sampled sequentially (rather than simultaneously) due to limitations in the TCS3200-DB breakout board design; here, one cycle of data collected in either a 5 s or a 30 s sampling interval. Regardless of the interval, the RGB sensors are activated 800 ms apart, with all six sensors collecting and reporting data 4.8 s into the cycle. On a 5 s sampling interval, the instrument pauses for 200 ms before starting the next cycle. For a 30 s cycle, the instrument pauses for 25.2 s.

RGB measurements collected by the TCS3200-DB breakout boards are converted to a sequence of digital pulses proportional to the intensity values and sent to the PT3 microcontroller. The PT3 board counts the pulses over each 100 ms integration period and stores the results in flash memory. In addition, the microcontroller controls sensor timing and distributes regulated power to the entire system from the USB supplied 5Vsource. Alternatively, the PT3 can be powered through its DC barrel jack connected to either batteries or a 7.5 V AC/DC adapter.

A custom graphical user interface (GUI) was developed using LabWindows software (National Instruments, Austin, TX, USA); this interface communicates with PT3 through simple ASCII commands such as start, stop, unload data stored in firmware, and perform a flash memory erase. The PCB firmware is designed to run continuously once started, stopping only if the flash memory becomes full, the stop command is received, or a manual reset is performed. The firmware sends out data after every measurement cycle, so that if a computer is connected the results can be viewed on the GUI as they are received. The firmware requires no acknowledgement or handshaking during regular operation; it will continue to run even if the computer is disconnected or otherwise not available to receive data.

PT3 Pseudocode

Pseudocode for PT3.

Prototype Sensor Device (PT5)

The most important firmware details for the operation of PT5 are two counter/timers and a status flag. The real time counter (RTC) controls all timing events for the instrument. The RTCs period (5 s or 30 s, corresponding to the sampling interval) and its capture/compare value (the integration time, 100–500 ms) are variables and are set at the beginning of an experiment. The pulse counter is a 16-bit counter/timer used to integrate the signal from each color channel. It is reset after each individual measurement. The status flag tells the firmware what the instrument is currently doing. It has the following values:

- 0—RTC overflow event has occurred/start new measurement cycle
- 1—instrument is waiting for the TCS3200 sensor to stabilize
- 2—instrument is counting pulses over an integration period
- 3—finished counting all sensor channels/instrument is waiting for the RTC to overflow
- 4—stop command received and/or TCS3200 sensors are powered off
