

We applied different signal analysis pipelines to the same raw video sequences. As for the choice of integration time, this implied that we needed to find a setting that offered both good SPG and PPG results, preferably with as little as possible low-quality outliers. When evaluating SQL boxplots for various integration times, we noticed that overall, when going beyond 1200us, the chance of getting low quality outliers clearly rose, whereas for some volunteers the signal rose only marginally or insignificantly.

Here we present a subsection showing all integration times. Each figure shows 4 PPG and 4 SPG synchronous signals from a random volunteer, each figure at different integration times. We decided to show transmission and reflection measurements, which already contain coherent and incoherent signals to avoid repetition.

We agree with the reviewer, that this information might be interesting for some specialized readers, but in order to not disrupt the reading line of the overall article, we suggest providing with this information as supplementary material.

TRANSMISSION SIGNALS
