SUPPORTING INFORMATION

Analytical methods (HPLC-ESI-MS)

Samples were injected (10 μ L) and chromatographically separated using a reversed-phase C18 XSelect[®] HSS T3 column 2.1 x 50 mm, 2.5 particle size (WATERS, Ireland). A gradient profile was applied using water (eluent A) and acetonitrile (eluent B), acidified with 0.2% and 0.1 % formic acid respectively, as a mobile phase. Mass spectrometry data were collected in positive electrospray mode over the range of *m/z* 100-600. Source settings were maintained using a capillary voltage of 2.5 kV (compounds **8a** and **9a**), 3.5 kV (compound **12h**), or 4.0 kV (compound **13h**); a cone of 25 V (compounds **8a** and **9a**) or 30 (compounds **12h** and **13h**), source temperature, 120°C; desolvation temperature, 350 °C, and desolvation gas flow, 700 L/h.

Method A: Initial conditions were set up at 5% of B, after 2.0 min of isocratic step, a linear change to 100% of B in 8.0 min. 100% B was achieved in 10 min and held for 5 min to allow for the column washing before returning to the initial conditions. Column recondition was achieved over 5 min, proving a total run time of 20 min. The column was maintained at 30°C and a flow rate of 0.200 mL/min was used.

Method B: The gradient started with 100% of A, after 2.0 min of isocratic step, a linear change to 90% of B in 8.0 min. 100% B was achieved in 10 min and held for 5 min to allow for the column washing before returning to the initial conditions. Column recondition was achieved over 1 min and held for 7 min, proving a total run time of 23 min. The column was maintained at 30°C and a flow rate of 0.200 mL/min was used.
