

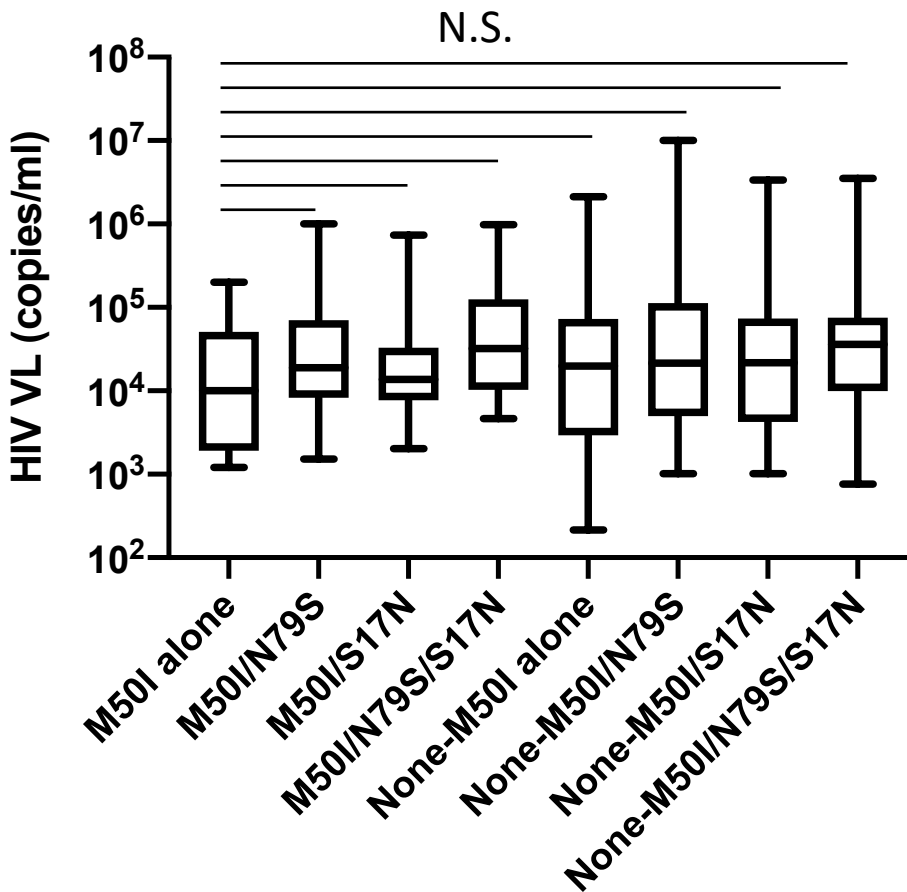

**Figure S1**

**Figure S1. Statistical analysis among VL and mutations**

To determine whether virus load (VL) in plasma and detected virus variants have a significant difference or not, we conducted the one-way ANOVA test between M50I alone and other combinations of mutations using a total of 529 samples.

None of the combinations showed significant differences in VL distribution with M50I mutation. N.S.: not significant ( $p > 0.05$ )
