

Supplementary Materials: Canadian potential healthcare and societal cost savings from consumption of pulses: a cost-of-illness analysis

Mohammad M.H. Abdullah, Christopher P.F. Marinangeli, Peter J.H. Jones, Jared G. Carlberg

Table S1. Summary of essential hypertension costs in Canada (Can \$ million).

	2008 ¹	2015 ²
<i>Direct costs</i>		
Hospital	38.2	40.0
Physician care	679.4	711.3
Drug	2,512	2,629
Total direct costs	3,229	3,381
<i>Indirect costs³</i>		
Due to Mortality	0.6	0.6
Due to Morbidity	NA	NA
Total indirect costs	0.6	0.6
Total costs	3,230	3,381

¹ From the EBIC Custom Report Generator 2008 data [1] with adjustments of inflation rates for year 2015 according to Statistics Canada Consumer Price Index [2]. NA, not available. ²Current dollars based on adjustments of inflation rates according to Statistics Canada Consumer Price Index [2]. ³ Indirect costs only include values of lost production due to reduced working time associated with illness, injury, or premature death, and do not include any valuation of morbidity and mortality themselves.

Table S2. Summary of essential hypertension total cost (direct + indirect) by province/territory in Canada (Can \$ million).¹

	Essential hypertension
Alberta	318.4
British Columbia	393.3
Manitoba	121.3
New Brunswick	89.0
Newfoundland and Labrador	66.5
Northwest Territories	2.3
Nova Scotia	116.1
Nunavut	2.0
Ontario	1,344
Prince Edward Island	16.8
Quebec	801.2
Saskatchewan	109.1
Yukon	1.2

¹ From the EBIC Custom Report Generator 2008 data [1] with adjustments of inflation rates for year 2015 according to Statistics Canada Consumer Price Index [2].

Table S3. Potential annual savings in healthcare and related costs of type 2 diabetes among Canadian adults from low glycaemic and/or high fiber diets that include pulses in Alberta (Can \$ million).¹

	Scenario			
	Very pessimistic	Pessimistic	Optimistic	Very optimistic
<i>Direct cost savings</i>				
Hospital care	0.1	0.2	0.3	0.6
Physician care	0.0	0.0	0.0	0.0

Total direct cost savings	0.5	1.4	2.4	4.8
<i>Indirect cost savings²</i>				
Due to Mortality	<0.1	<0.1	<0.1	<0.1
Due to Morbidity	NA	NA	NA	NA
Total indirect cost savings	<0.1	<0.1	<0.1	<0.1
Total cost savings	0.5	1.5	2.4	4.9

¹ Data represent type 2 diabetes-related financial savings following reduction in HbA1c concentrations with adoption of a low GI or high fiber diet that includes pulses for men and women [3]. Given that patients with T2D are expected to continue to visit their physicians, these costs remained unchanged. The very optimistic scenario is a long-term estimate of potential savings when 50% of Canadian adults (≥ 18 years of age) with T2D consume a low GI or high fiber diet with dietary pulses. The optimistic scenario is a medium-to-long-term pragmatic estimate of potential savings when 25% of adults in Canada with T2D use pulses to adopt a low GI or high fiber diet. The pessimistic and very pessimistic scenario is a practical short-to-medium-term, and immediate estimate of cost savings that could follow when 15% and 5% of adults with T2D follow a low GI or high fiber diet with pulses. NA, not available. ² Indirect costs only include values of lost production due to reduced working time associated with illness, injury, or premature death, and do not include any valuation of morbidity and mortality themselves.

Table S4. Potential annual savings in healthcare and related costs of type 2 diabetes among Canadian adults from low glycaemic and/or high fiber diets that include pulses in British Columbia (Can \$ million).¹

¹ Data represent cardiovascular disease-related financial savings following reductions in LDL-cholesterol concentrations and systolic blood pressure with the consumption of 100 g/day pulses for men and women [3]. The very optimistic scenario is an estimate of potential savings when 50% of Canadian adults (≥ 18 years of age)

consume one 100 g/day serving of dietary pulses. The optimistic scenario is a medium-to-long-term pragmatic estimate of potential savings when 25% of adults in Canada consume pulse regularly. The pessimistic scenario is a practical short-to-medium-term estimate of cost savings that could follow the dietary pulse consumptions among 15% of adults. The very pessimistic scenario is an immediate estimate when 5% of Canadian adults adopt 100 g/day serving of pulses. LDL-C, LDL-cholesterol; NA, not available; SBP, systolic blood pressure.² Indirect costs only include values of lost production due to reduced working time associated with illness, injury, or premature death, and do not include any valuation of morbidity and mortality themselves.

¹ Data represent cardiovascular disease-related financial savings following reductions in LDL-cholesterol concentrations and systolic blood pressure with the consumption of 100 g/day pulses for men and women [3]. The very optimistic scenario is an estimate of potential savings when 50% of Canadian adults (≥ 18 years of age)

consume one 100 g/day serving of dietary pulses. The optimistic scenario is a medium-to-long-term pragmatic estimate of potential savings when 25% of adults in Canada consume pulse regularly. The pessimistic scenario is a practical short-to-medium-term estimate of cost savings that could follow the dietary pulse consumptions among 15% of adults. The very pessimistic scenario is an immediate estimate when 5% of Canadian adults adopt 100 g/day serving of pulses. LDL-C, LDL-cholesterol; NA, not available; SBP, systolic blood pressure.² Indirect costs only include values of lost production due to reduced working time associated with illness, injury, or premature death, and do not include any valuation of morbidity and mortality themselves.

¹ Data represent cardiovascular disease-related financial savings following reductions in LDL-cholesterol concentrations and systolic blood pressure with the consumption of 100 g/day pulses for men and women [3]. The very optimistic scenario is an estimate of potential savings when 50% of Canadian adults (≥ 18 years of age)

consume one 100 g/day serving of dietary pulses. The optimistic scenario is a medium-to-long-term pragmatic estimate of potential savings when 25% of adults in Canada consume pulse regularly. The pessimistic scenario is a practical short-to-medium-term estimate of cost savings that could follow the dietary pulse consumptions among 15% of adults. The very pessimistic scenario is an immediate estimate when 5% of Canadian adults adopt 100 g/day serving of pulses. LDL-C, LDL-cholesterol; NA, not available; SBP, systolic blood pressure.² Indirect costs only include values of lost production due to reduced working time associated with illness, injury, or premature death, and do not include any valuation of morbidity and mortality themselves.

Table S27. Potential annual savings in healthcare and related costs of cardiovascular disease among Canadian adults from 100 g/day dietary pulse intake in Saskatchewan (Can \$ million).¹

	Scenario			
	Very pessimistic	Pessimistic	Optimistic	Very optimistic
Cost savings following LDL-C reduction				
<i>Direct cost savings</i>				
Hospital care	0.1	0.3	0.4	0.9
Physician care	0.1	0.4	0.7	1.4
