

**SUPPLEMENTARY FIGURES**

**Supplementary Figure S1.** Associations between pre-NAC TILs and month in whole population, and after stratification by breast cancer subtype. Bottom and top bars of the boxplots represent the first and third quartiles, respectively, the medium bar is the median, and whiskers extend to 1.5 times the interquartile range. **A**, Pre-NAC str TIL levels according to month. **B**, Pre-NAC IT TIL levels according to month. **C**, Pre-NAC str TIL levels according to month and breast cancer subtype. **D**, Pre-NAC IT TIL levels according to month and breast cancer subtype.

**Supplementary Figure S2.** Barplot of associations between response to treatment and season at breast cancer diagnosis in the whole population, and by chemotherapy regimen. **A**, among the whole population. **B**, by chemotherapy regimen.

**Supplementary Figure S3.** RCB class distribution among the whole population and by season at breast cancer diagnosis. **A**, among the whole population. **B**, in each season.

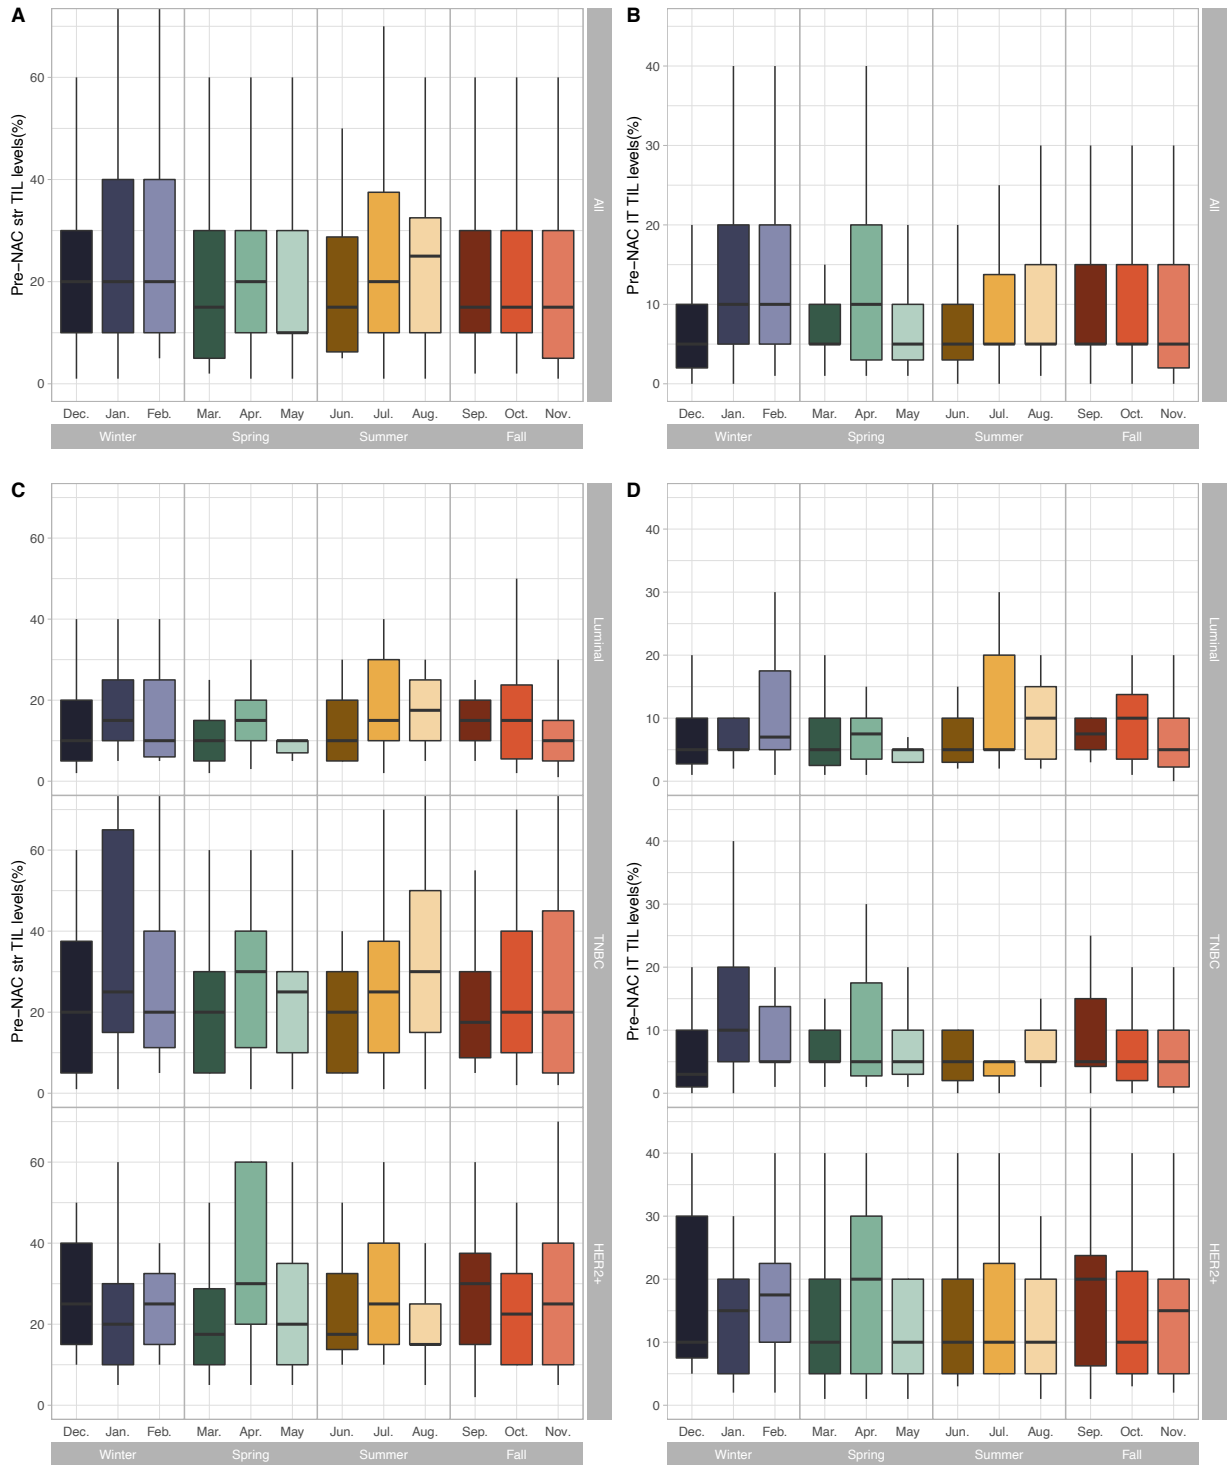

**Supplementary Figure S4.** Post-NAC TIL levels by season at BC diagnosis in the general population and by breast cancer subtype. Differences among seasons. The first and third quartiles are represented by the bottom and top bars of the boxplots, respectively; the median is represented by the medium bar, and whiskers extend to 1.5 times the interquartile range. **A**, stromal lymphocytes among the whole population. **B**, stromal lymphocytes in each BC subtype.

**Supplementary Figure S5.** Associations between post-NAC TILs and month in whole population, and after stratification by breast cancer subtype. Bottom and top bars of the boxplots represent the first and third quartiles, respectively, the medium bar is the median, and whiskers extend to 1.5 times the interquartile range. **A**, Post-NAC str TIL levels according to month. **B**, Post-NAC IT TIL levels according to month. **C**, Post-NAC str TIL levels according to month and breast cancer subtype. **D**, Post-NAC IT TIL levels according to month and breast cancer subtype.

**Supplementary Figure S6.** Distant relapse-free survival curves by season at BC diagnosis. **A**, Distant relapse-free survival curves according to season. **B**, Distant relapse-free survival curves in Luminal breast cancer according to season. **C**, Distant relapse-free survival curves in TNBC breast cancer according to season. **D**, Distant relapse-free survival curves in Her2-positive breast cancer according to season.

**Supplementary Figure S7.** Forest plot – Hazard Ratio RFS (Univariate analysis). Survival impact of neoadjuvant chemotherapy (NAC) strategy according to variables – Recurrence Free Survival (RFS).

## Pre-NAC immune infiltration rates according to the months of the year at BC diagnosis

BC patients with pre-NAC str TIL levels available [n=717] and IT TIL levels [717]

**Supplementary Figure S1.** Associations between pre-NAC TILs and month in whole population, and after stratification by breast cancer subtype. Bottom and top bars of the boxplots represent the first and third quartiles, respectively, the medium bar is the median, and whiskers extend to 1.5 times the interquartile range. **A**, Pre-NAC str TIL levels according to month. **B**, Pre-NAC IT TIL levels according to month. **C**, Pre-NAC str TIL levels according to month and breast cancer subtype. **D**, Pre-NAC IT TIL levels according to month and breast cancer subtype.

BC patients with pCR rates available treated with NAC [(n=1193); Taxane-Anthracycline-based (n= 844), Anthracycline-based (n= 234), Taxane-based (n= 24), Others (n= 90)]

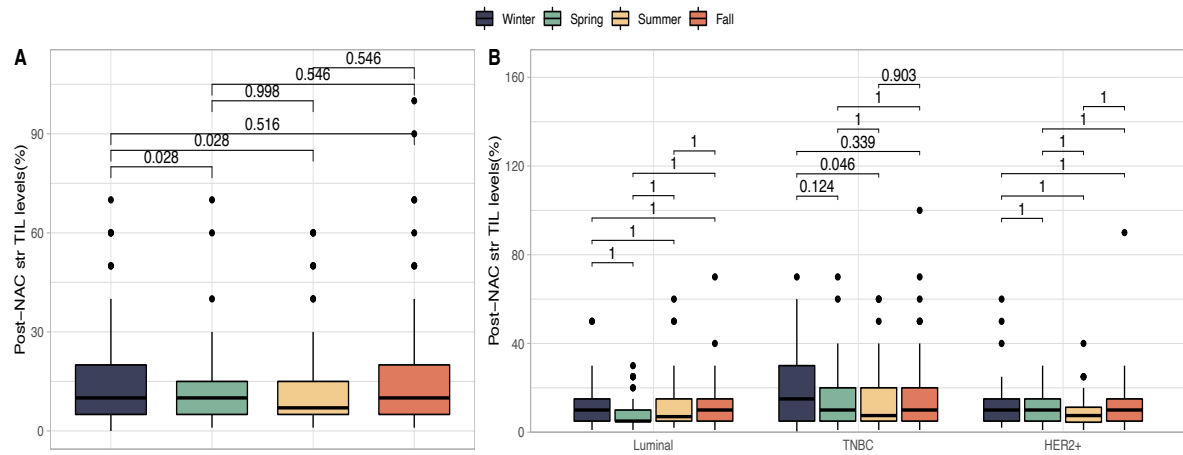

**Supplementary Figure S2.** Barplot of associations between response to treatment and season at breast cancer diagnosis in the whole population, and by chemotherapy regimen. **A**, among the whole population. **B**, by chemotherapy regimen.

**Supplementary Figure S3.** RCB class distribution among the whole population and by season at breast cancer diagnosis. **A**, among the whole population. **B**, in each season.

## Post-NAC immune infiltration rates according to the season at BC diagnosis.

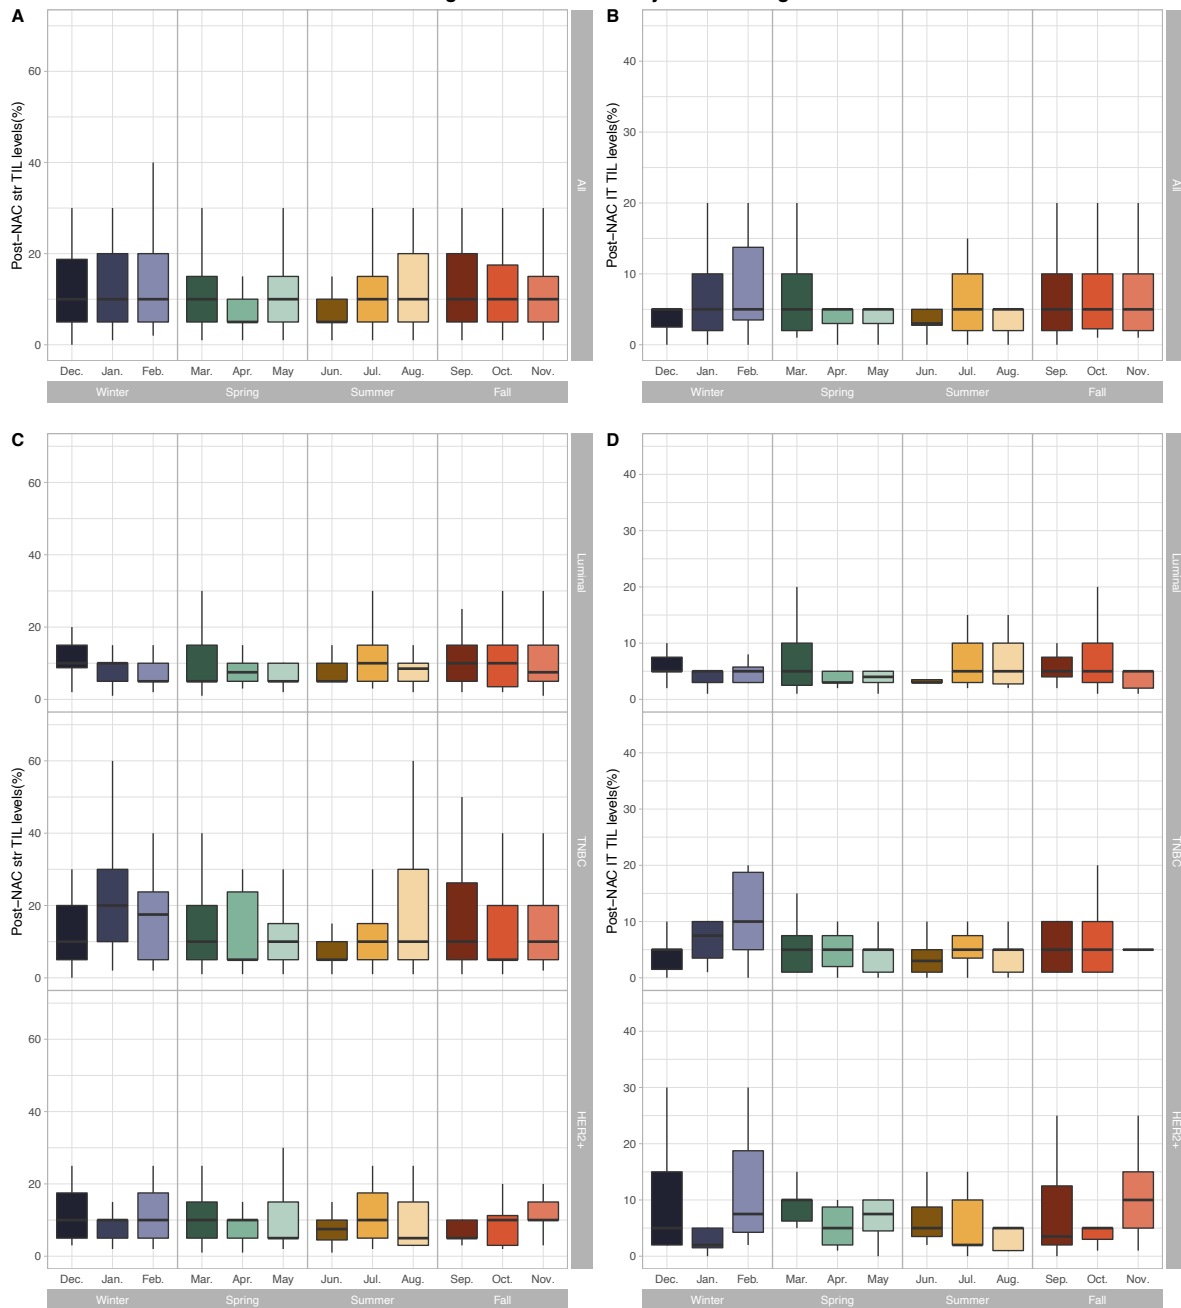

Wilcoxon test one by one (adjusted p-values)

BC patients with post-NAC str TIL levels available [n=717]

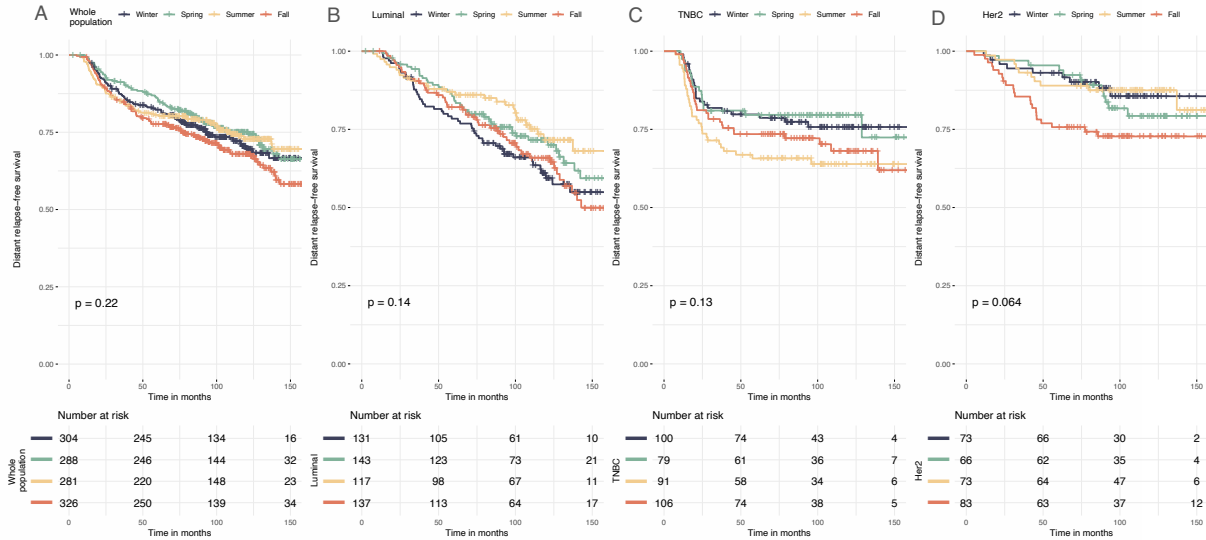

**Supplementary Figure S4.** Post-NAC TIL levels by season at BC diagnosis in the general population and by breast cancer subtype. Differences among seasons. The first and third quartiles are represented by the bottom and top bars of the boxplots, respectively; the median is represented by the medium bar, and whiskers extend to 1.5 times the interquartile range. **A**, stromal lymphocytes among the whole population. **B**, stromal lymphocytes in each BC subtype.

## Post-NAC immune infiltration rates according to the months of the year at BC diagnosis

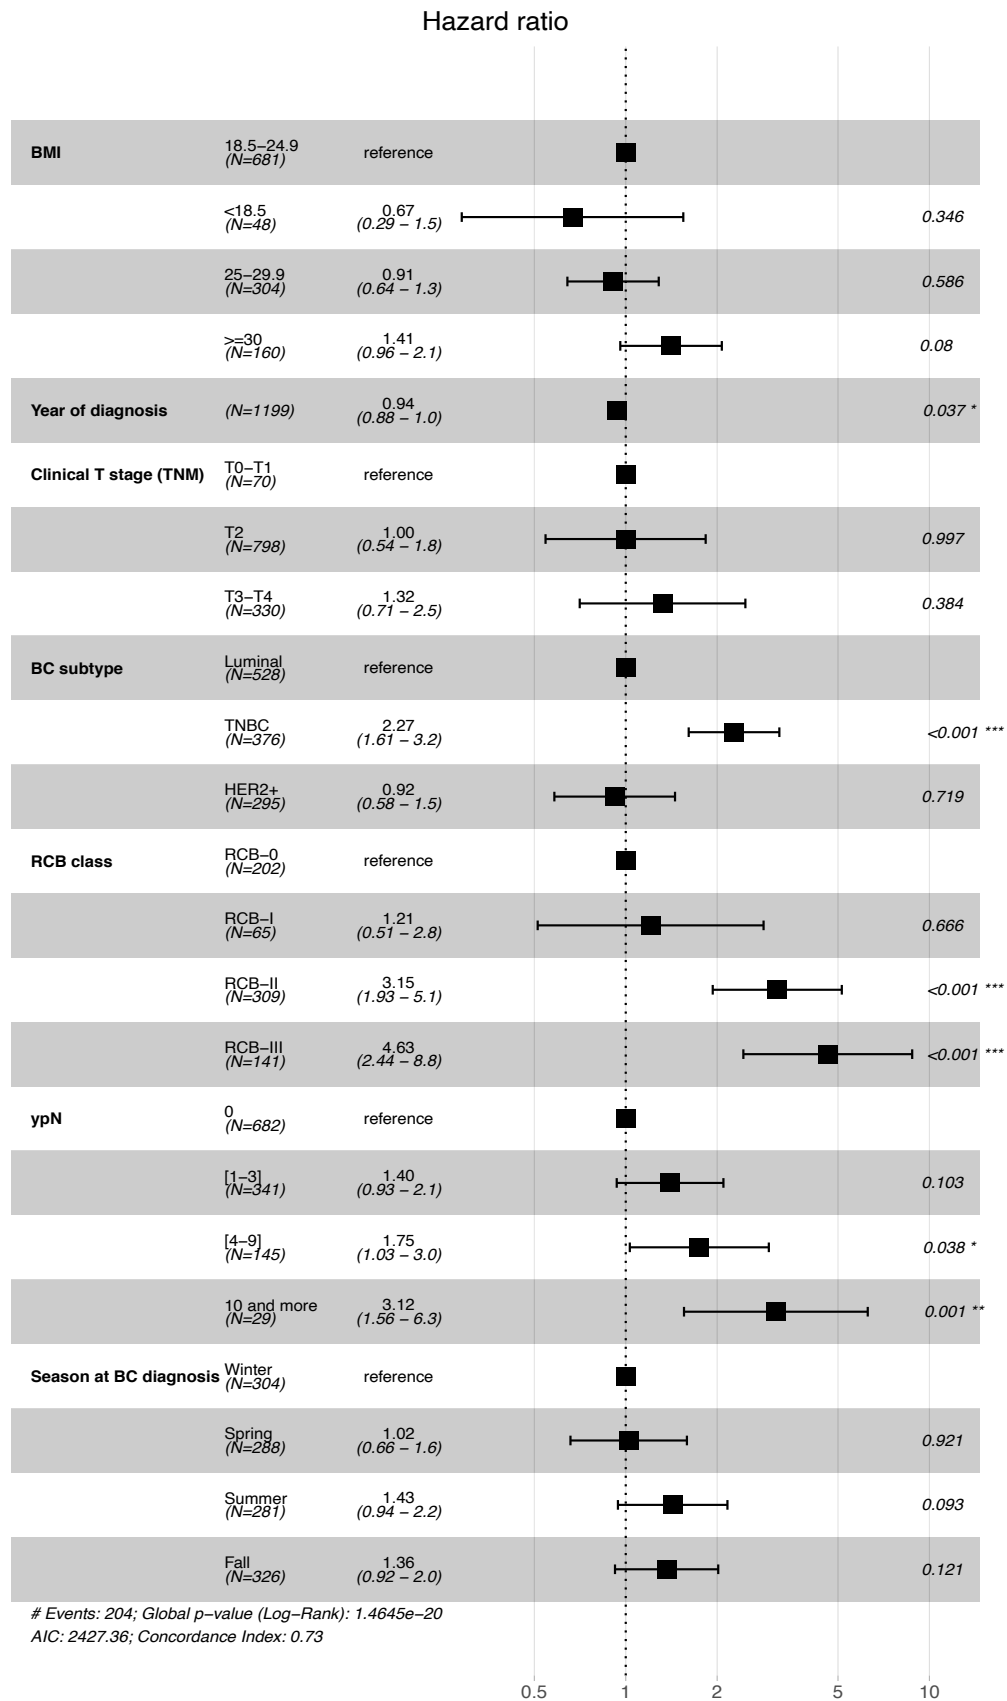

BC patients with post-NAC str TIL levels available [n=717] and IT TIL levels [483]

**Supplementary Figure S5.** Associations between post-NAC TILs and month in whole population, and after stratification by breast cancer subtype. Bottom and top bars of the boxplots represent the first and third quartiles, respectively, the medium bar is the median, and whiskers extend to 1.5 times the interquartile range. **A**, Post-NAC str TIL levels according to month. **B**, Post-NAC IT TIL levels according to month. **C**, Post-NAC str TIL levels according to month and breast cancer subtype. **D**, Post-NAC IT TIL levels according to month and breast cancer subtype.

**Supplementary Figure S6.** Distant relapse-free survival curves by season at BC diagnosis. **A**, Distant relapse-free survival curves according to season. **B**, Distant relapse-free survival curves in Luminal breast cancer according to season. **C**, Distant relapse-free survival curves in TNBC breast cancer according to season. **D**, Distant relapse-free survival curves in Her2-positive breast cancer according to season.

**Supplementary Figure S7.** Forest plot – Hazard Ratio RFS (Univariate analysis). Survival impact of neoadjuvant chemotherapy (NAC) strategy according to variables – Recurrence Free Survival (RFS).

**SUPPLEMENTARY TABLES****Supplementary Table S1.** Patients 'characteristics according to season in each tumor subtype.

*Missing data: Missing data:* Menopausal status, n=10; BMI, n=6; Smoking status, n=243; Hereditary predisposition, n=932; Clinical Tumor size (mm), n=1; Clinical T stage (TNM), n=1; Clinical N stage (TNM), n=1; SBR grade, n=42; KI67, n=617; Mitotic index, n=118; DCIS component, n=206; Stromal TIL levels (%), n=482; IT TIL levels (%), n=482; LVI, n=761; Histological type, n=63; Pathological complete response, n=6; RCB index (continuous), n=482; Residual Cancer Burden class, n=482; ypN, n=2; Stromal TIL levels (%) (post-NAC), n=482; IT TIL levels (%) (post-NAC), n=716.

*Abbreviations:* BMI=body mass index; NST= no special type; TNBC= triple negative breast cancer; str TILs= stromal tumor-infiltrating lymphocytes; IT TILs= intratumoral-infiltrating lymphocytes; pCR=Pathologic complete response. The "n" denotes the number of patients. In case of categorical variables, percentages are expressed between brackets. In case of continuous variables, mean value is reported. In case of nonnormal continuous variables, median value is reported, with interquartile range between brackets.

**Supplementary Table S2.** Association of season with pCR after univariate analysis in the whole population.

*Missing data: Missing data:* Menopausal status, n=10; BMI, n=6; Smoking status, n=243; Hereditary predisposition, n=932; Clinical Tumor size (mm), n=1; Clinical T stage (TNM), n=1; Clinical N stage (TNM), n=1; SBR grade, n=42; KI67, n=617; Mitotic index, n=118; DCIS component, n=206; Stromal TIL levels (%), n=482; IT TIL levels (%), n=482; LVI, n=761; Histological type, n=63; Pathological complete response, n=6; RCB index (continuous), n=482; Residual Cancer Burden class, n=482; ypN, n=2; Stromal TIL levels (%) (post-NAC), n=482; IT TIL levels (%) (post-NAC), n=716.

*Abbreviations:* BMI=body mass index; NST= no special type; TNBC= triple negative breast cancer; str TILs= stromal tumor-infiltrating lymphocytes; IT TILs= intratumoral-infiltrating lymphocytes; pCR=Pathologic complete response. The "n" denotes the number of patients. In case of categorical variables, percentages are expressed between brackets. In case of continuous variables, mean value is reported. In case of nonnormal continuous variables, median value is reported, with interquartile range between brackets.

**Supplementary Table S3.** Literature Review

*Abbreviations:* PR= progesterone receptor; ER= estrogen receptor; HR= hormone receptor; BC= breast cancer; HR= hazard ratio.

*Supplementary Table S2. Association of season with pCR after univariate analysis in the whole population.*

Authors	Country	Journal	Type of source	Research design	Number of Patients (n)	Study population	Summary points
Cohen (1983)	Israel	Cancer Research	Research	Registry	2,948	Breast cancer with histopathological confirmation	There was a seasonal variation in the incidence of nonlocalized breast cancer diagnosis, with a peak during spring.
Holdaway (1990)	New Zealand	Cancer Research	Research	Prospective Cohort	2,706	Breast cancer	According to the month of initial tumor detection, tissue sampling, or surgery, there was a significant annual variation in PR receptor concentration. PR receptor concentrations were higher in patients diagnosed or operated on during April. There is also a significant cyclic variation in the month of detection of breast cancer with peak detection occurring in December (summer).
Mason (1990)	New Zealand	British Journal of Cancer	Research	Prospective Cohort	2,245	Incident breast cancer	Breast cancer diagnoses in spring and summer were associated with better survival. These patterns have been different according to the menopausal status and hormonal receptors. Postmenopausal women with ER positive tumours had 13% improvement in survival at 5 years if the initial tumour was detected in spring/summer ( $p < 0.0003$ , OR 2.04 [CI 1.38-3.01]). Premenopausal women with HR positive tumours there was no significant relationship between season of detection and survival. However, premenopausal patients had improved survival (26% at 5 years) if they had HR tumours which were found initially in the spring/summer.
Joensuu (1991)	Finland	British Journal of Cancer	Research	Retrospective Cohort	401	Invasive, non bilateral breast cancer patients	Cancers diagnosed during January, February, or July-August to September-October had a poorer prognosis, further tumor necrosis, advanced mitotic count, and larger tumor size than if the diagnosis was made during the rest of the year ( $p = 0.03$ and $0.009$ , respectively).
Ross (1997)	USA	Breast Cancer Research and Treatment	Short Communication	Case-control study	2,895	Breast cancer self-detected that required surgery	There was a statistically significant seasonal variation in the detection of BC, with peaks occurring in spring and late fall. Women under 40, had a spring peak detection ( $p = 0.089$ ) and women $\geq 40$ in late fall ( $p = 0.063$ ). The seasonal variation in detection was statistically significant only for the estrogen receptor-negative tumors ( $p = 0.003$ ).
Gao (2001)	Singapore	British Journal of Cancer	Short Communication	Registry	3,219	Breast cancer, histologically confirmed	There is no clear cut seasonal pattern, although fewer cases are diagnosed in January and February (close to the Western and Chinese New Year festivals). They appeared more numerous approximately six months later over the June to August period. Also, there were more ER+/PR+ BC in October, and tumors were bigger ( $\geq 1$ cm) if diagnoses were made in August.
Paradiso (2001)	Italy	Breast Cancer Research and Treatment	Research	Retrospective Cohort	903	T1-3, N0-1M0 Invasive breast cancer, treated with radical mastectomy or lumpectomy and lymphadenectomy	There were no differences in nodal status or tumor size, ER, and PgR across seasons in the general population. Grade III tumors were significantly more frequent in spring. These patterns have been different according to the menopausal status of the patient. In premenopausal BC patients, ER had a peak in January and April; PgR in July ( $p < 0.05$ ). Also, tumor size had peaks in May and December ( $p < 0.01$ ). In menopausal patients, ER had a rise in November, no significant reproducible rhythm was reported for PgR, and tumor size had a peak in September.
Lambe (2003)	Sweden	British Journal of Cancer	Short Communication	Registry	60,143	Breast cancer	There was a seasonal variation in breast cancer detection, decreasing during the summer (-16.7%).
Lim (2006)	United Kingdom	International Journal of Cancer	Research	Registry	182,895	Breast cancer	Breast cancer diagnoses in summer and autumn were associated with better survival compared to breast cancer diagnoses in winter (HR 0.86 [95% CI 0.83-0.89]).
Porojnicu (2007)	Norway	Breast Cancer Research and Treatment	Research	Registry	49,821	Breast cancer	Breast cancer diagnoses in summer had better prognosis (RR of death 15-25% lower for summer diagnosis versus winter diagnosis). There was no significant seasonal variation of the number of new cases.
Roychoudhury (2008)	United Kingdom	International Journal of Cancer	Research	Registry	187,263	Breast cancer	Diagnosis within the summertime season becomes related to significantly reduced mortality in the first month of diagnosis compared with winter (HR 0.81 [95% CI, 0.75-0.86]). However, at long-time follow-up ( $> 5$ years), there has been a steady shift within the seasonality pattern, with an autumn diagnosis related to reduced mortality (HR 0.93 [95% CI, 0.90-0.96]).

Supplementary Table S3. Literature Review

Authors	Country	Journal	Type of source	Research design	Number of Patients (n)	Study population	Summary points
Holmberg (2009)	Sweden	Cancer Causes Control	Research	Registry	89 630	Breast cancer	There was a higher HR of death in women diagnosed with BC in the summer (August vs January, HR 1.14 [95% CI, 1.09–1.19]). This difference coincided with a lower mean number of cases diagnosed per day, and a higher proportion of advanced cases diagnosed in the summer.
Stajner (2009)	Atlanta, Connecticut, Detroit, Hawaii, Iowa, New Mexico, San FranciscoOakland, Seattle, Puget Sound, and Utah	International Journal of Cancer	Letter to editor	Registry	184 434	Breast cancer	After 12 years of follow up, BC diagnosed in winter between 1980–1986 had the highest cumulative probability of death [HR 0.32 [95% CI, 0.315–0.33] and the lowest if cases diagnosed in autumn (HR 0.29[95% CI,0.29–0.30]) and spring (HR 0.30[95% CI, 0.29–0.31]). However, for each of the other 2 periods (1973–1979 and 1987–1993) prognosis from BC was independent of the seasonality of the diagnosis.
Oh (2010)	International study (88 cancer registries)	Breast Cancer Research and Treatment	Research	Registry	2 921 714	Breast cancer	Breast cancer is diagnosed more often in spring and fall, both in the Northern and Southern Hemispheres. This seasonality is increasingly more prominent as population distance from the equator increases and this latitude dependence is most pronounced among women living in rural areas.
Teilum (2011)	Denmark	British Medical Journal Open	Research	Registry	79 658	Early invasive breast cancer that required surgery	There were no evidence of a seasonal variation in the survival after surgery for early BC
Kwon (2013)	Korean	Korean Journal of Clinical Oncology	Research	Registry	11 698	Breast cancer	There were no differences in patient characteristics and ER, PR, tumor size, and lymph node involvement among the breast cancers diagnosed in spring/summer vs. autumn/winter, except for age ( $p < 0.01$ ) and HER2 status ( $p = 0.02$ ). Also, there were no differences in survival and relapse rates.
Mutlu (2013)	Turkey	Asian Pacific Journal of Cancer Prevention	Research	Retrospective Cohort	517	Breast cancer	It was not found any statistically significant differences among groups regarding age, menopause status, stage of breast cancer, ER, PgR, Her2+, grade, lymphovascular invasion. Patients whose were diagnosed in winter had best mean DFS while summer group had worst DFS. When we evaluated mean OS, we did not find any differences ( $p=0.637$ ).
Ho (2014)	USA	Medical Science Monitor	Research	Registry	19 204	Breast cancer	BC diagnoses in summer had better prognosis than BC diagnoses in winter at all latitudes (HR 0.94 [95% CI, 0.94 to 0.94], $p = 0.002$ ).
Kuzmickiene (2018)	Lithuania	Journal of Cancer Research and Therapeutics	Research	Retrospective Cohort	991	Non-metastatic breast cancer patients	BC diagnosis in summer and autumn had a 40% reduced risk for 0–3-year mortality when compared to those diagnosed in spring. The impact season of diagnosis on mortality was most pronounced in young patients. BC diagnosis in autumn is an independent predictor factor for better overall prognosis in women under the age of 50 years (HR = 0.61 [95% CI] 0.39–0.96, $p = 0.003$ ).
Tas (2021)	Turkey	Indian Journal of Surgery	Letter to editor	Retrospective Cohort	5 477	Breast cancer	The number of newly diagnosed breast cancer patients is significantly lower in summer than in any other season (summer (22.0%) vs spring (27.0%), autumn (25.6%) and winter (25.3%).
Wu (2021)	USA	Journal of Clinical Medicine	Research	Prospective Cohort	2 919	Primarily early stage breast cancer	Blood collected in the winter season was associated with lower C-reactive (CRP) protein when compared to summer. In addition, moderate intakes of red meat were associated with reducing CRP in winter but not in other seasons. Increased intakes of fruit and vegetables were associated with reduced inflammation in most seasons except winter.
Yoon (2021)	Korea	Journal of Gastroenterology and Hepatology	Research	Retrospective Cohort	1 313	Breast cancer	There was a winter peak for breast cancer detection (72.7–76.3%) higher than for other cancers: thyroid cancer (44.1–59.4%), lung cancer (36.8–41.7%), kidney cancer (34.141.2%), and prostate cancer (27.7–34.7%).

Supplementary Table S3. Literature Review (continuation)
