Abstract: The development of new heterogeneous Pt-containing catalysts has retained its relevance over the past decades. The present paper describes the method to produce metal–carbon composites, Pt_{1-x}Ni_x/CNF, with an adjustable Pt/Ni ratio. The composites represent Pt_{1-x}Ni_x (x = 0.0–1.0) nanoparticles embedded within a structure of carbon nanofibers (CNF). The synthesis of the composites is based on a spontaneous disintegration of Pt_{1-x}Ni_x alloys in an ethylene-containing atmosphere with the formation of CNF. The initial Pt_{1-x}Ni_x alloys were prepared by thermolysis of multicomponent precursors. They possess a porous structure formed by fragments of 100–200 nm. As was shown by X-ray diffraction analysis, the crystal structure of the alloys containing 0–30 and 60–100 at.% Ni corresponds to a *fcc* lattice based on platinum (*Fm-3m*), while the Pt_{0.50}Ni_{0.50} sample is an intermetallic compound with the tetragonal structure (*P4/mmm*). The impact of the Ni content in the Pt_{1-x}Ni_x samples on their activity in ethylene decomposition was studied as well. As was revealed, the efficiency of Pt_{1-x}Ni_x alloys in this process increases with the rise of Ni concentration. The composite samples were examined in an electrochemical hydrogen evolution reaction. The synthesized Pt_{1-x}Ni_x/CNF composites demonstrated superior activity if compared with the Pt/Vulcan commercial catalyst.

1. Introduction

Nowadays, fuel cells are considered a real alternative to energy sources working on fossil fuels [1,2]. Due to their attractive performance characteristics, such as high efficiency, low emissions, quiet operation, and portability, fuel cells differ from other alternative energy sources, which opens up opportunities for their application in cars and portable electronics. Low-temperature fuel cells based on a proton-exchange membrane fuel cell (PEMFC) are of greatest interest [3,4]. The key component of such fuel cells is a membrane-electrode block, on the anode and cathode of which the catalytic reactions of fuel oxidation (hydrogen, methanol, or formic acid) [5–8] and oxidant reduction (air oxygen) [9] proceed, respectively. The most widely used catalyst in fuel cells is platinum, the use of which is disadvantaged by its high cost [10–12]. The use of bimetallic (alloy) catalytic systems based on platinum with the inclusion of other cheaper metals, which give the catalysts the desired properties, can solve these problems. The introduction of the second metal can result in a certain improvement in the stability of the catalyst and an increase in the duration of its operation. For example, bimetallic Pt-M catalysts possess a significantly higher tolerance towards CO impurities contained in the fuel if compared to pure platinum [13]. As second metals, Co, Ni, Fe, Ru, and Cr are widely studied [14–16]. Unlike clusters of pure Pt, particles of Pt-M alloys have a lower tendency to agglomerate. The presence of an alloying

component decreases the mobility of Pt on the support [17,18]. In addition, the use of alloys has a positive effect on the resistance of platinum catalysts to corrosion in acidic and alkaline media [19]. The alloys are more tolerant to methanol as well since alloying metals suppress Pt dissolution and prevent methanol adsorption on the catalyst's surface [20,21]. Thus, an important scientific problem is the creation of catalytic systems characterized by high stability under the conditions of the long-term operation of fuel cells. The use of alloy particles is one of the approaches allowing for improvement of the stability of the catalysts used in the fuel cells. In the future, such materials may replace the currently used monometallic platinum catalysts.

Most commonly, electrochemical catalysts containing alloy particles of platinum with other metals are prepared via impregnation of the carbon support with a solution of metal salts, followed by heat treatment or chemical reduction (for example, sodium borohydride) [22–26]. Many catalysts containing bi- or trimetallic nanosized alloy particles distributed over the surface of the carbon support have been thus obtained. Among them, systems such as $Pt_{1-x}Co_x/C_{Vulcan}$ [27], $Pt_{1-x}Ni_x/C_{Vulcan}$ [28,29], $Pt_{1-x}Fe_x/C_{Vulcan}$ [14,30], $Pt_{1-x}Fe_x/N-C$ [31], $Pt_{1-x}Cu_x/C$ [32,33], $PtNi_3Cr/C$ [32], $Pt_{1-x}Sn_x/C_{graphene}$ [34], $Pt_{1-x}Ru_x/N-C$ [35], and $Pt_{1-x}Pb_x/C_{Vulcan}$ [36] should be mentioned. These catalysts exhibit sufficiently high activity in the reactions of oxygen reduction and methanol or hydrogen oxidation. The mentioned approach is relatively easy to use but does not guarantee a narrow particle size distribution. The main disadvantage of the impregnated catalysts is the remaining tendency of deposited alloy particles to deactivate due to their washing out or surface migration and agglomeration.

Another approach, the synthesis of carbon nanofibers (CNF) by catalytic chemical vapor deposition (CCVD) on alloys of a given composition, seems to be more promising for the preparation of electrochemical catalysts [37–40]. By using this method, it is possible to obtain a composite catalyst, in which the active alloy particles are embedded within the structure of carbon nanofibers. Such composites are expected to be resistant to leaching and agglomeration processes. Note that, in this case, the synthesis of carbon material, which acts as a support of alloy particles, occurs directly during the catalytic decomposition of hydrocarbons over these particles. At the initial stage of this process, carbon erosion (CE) of the initial bulk alloy occurs. During CE, the initial alloy rapidly disintegrates with the formation of dispersed particles, which then play the role of active centers for the growth of carbon filaments [41]. The activity of platinum-containing alloys in the decomposition of hydrocarbons and their chlorine derivatives is well reported in the literature [40,42,43]. It has been shown that, under the conditions of the controlled decomposition of ethylene over $Pt_{1-x}Co_x$ nanoalloys, it is possible to obtain Pt-Co/CNF composite systems with a given phase composition and a variable concentration of active alloy particles [40]. Further development of approaches to produce Pt-containing composites $Pt_{1-x}M_x/CNF$ ($M = Co, Fe, Ni$) of controllable composition, as well as their characterization, seems to be an actual challenge.

Thereby, the present work aimed at the synthesis and characterization of $Pt_{1-x}Ni_x/CNF$ composites, which are nanoalloy particles embedded within the CNF structure. The most commonly used preparation methods to obtain the carbon-based Pt-Ni electrocatalysts are summarized in Table S1. The novelty of the used approach is in its controllable and target application of the carbon erosion process for the synthesis of such structures from microdispersed alloys of the desired composition. Thus, the composites were prepared via catalytic decomposition of ethylene over porous $Pt_{1-x}Ni_x$ ($x = 0.0–1.0$) nanoalloys. The phase composition and microstructure of porous alloys were studied using powder X-ray diffraction analysis and electron microscopy. Based on the data obtained, optimal conditions for the synthesis of $Pt_{1-x}Ni_x/CNF$ composites were determined. The synthesized $Pt_{1-x}Ni_x/CNF$ composites were compared with the commercial (20 wt.%)Pt/Vulcan catalyst in activity in the hydrogen evolution reaction (HER).

2. Results and Discussion

2.1. Synthesis and Characterization of $Pt_{1-x}Ni_x$ Alloys

In the first stage of the work, the samples of $Pt_{1-x}Ni_x$ porous alloys were synthesized by thermolysis of multicomponent precursors. These precursors represent micro-heterogeneous mixtures of the complex salts $[Pt(NH_3)_4]Cl_2 \cdot H_2O$ and $[Ni(NH_3)_6]Cl_2$ obtained by fast co-precipitation of an aqueous solution of the salts in cooled acetone. According to the element analysis data (Table 1), the compositions of the obtained alloys correspond to the ratio of metals specified during the synthesis of the precursors. Figure 1 shows the X-ray diffraction (XRD) patterns of the resulting $Pt_{1-x}Ni_x$ alloys. The XRD pattern of the reference sample $Pt_{1.00}$ is in full accord with information in the database for the Pt standard (space group $Fm-3m$, ICDD PDF-2 #4-802 [44]). The diffraction patterns of the samples with Ni content of 0–30 and 60–100 at.% show a set of reflections corresponding to the phase of the face-centered cubic (*fcc*) solid solution only. The reflections of the *fcc* phase present in the $Pt_{1-x}Ni_x$ samples are shifted towards far 2θ angles concerning pure Pt. This indicates the incorporation of nickel atoms into the platinum lattice with the formation of the *fcc* alloy. The $Pt_{0.50}Ni_{0.50}$ sample contains a tetragonal phase with the PtNi intermetallic structure (space group $P4/mmm$, ICDD PDF-2 #65-2797 [44]) and a small amount of the *fcc* alloy phase. Thereby, the phase compositions of the synthesized $Pt_{1-x}Ni_x$ samples are in good agreement with the phase diagram of the Pt-Ni system [45,46]. It should be noted that the composition of alloy phases determined from diffraction data using the calibration dependence of the specific atomic volume of the alloy on the Pt content [45] is consistent with the nominal metal content in the samples determined by the ICP-AES method (Table 1).

Figure 1. XRD patterns of pure Ni and Pt samples and $Pt_{1-x}Ni_x$ ($x = 0.30$ – 0.90) alloys. Asterisks (*) show the superstructural reflections of the PtNi intermetallic phase.

Table 1. Chemical composition and crystallographic characteristics of synthesized $\text{Pt}_{1-x}\text{Ni}_x$ ($x = 0.0\text{--}1.0$) alloys.

#	Preset Composition, at.% Ni	Nominal Composition, at.% Ni	Phase	Phase Structure	Lattice Parameter, Å
1	0	0	Pt	<i>fcc</i>	3.9232(5)
2	30	29 ± 2	$\text{Pt}_{0.70}\text{Ni}_{0.30}$	<i>fcc</i>	3.8245(5)
3	50	51 ± 4	PtNi	tetragonal	$a = 2.690(2)$ $c = 3.617(2)$
4	60	61 ± 5	$\text{Pt}_{0.47}\text{Ni}_{0.53}$	<i>fcc</i>	3.739(2)
5	70	70 ± 5	$\text{Pt}_{0.40}\text{Ni}_{0.60}$	<i>fcc</i>	3.708(2)
6	80	80 ± 6	$\text{Pt}_{0.30}\text{Ni}_{0.70}$	<i>fcc</i>	3.667(2)
7	90	90 ± 7	$\text{Pt}_{0.19}\text{Ni}_{0.81}$	<i>fcc</i>	3.619(2)
8	100	100	Ni	<i>fcc</i>	3.575(2)
					3.5242(5)

The morphology and secondary structure of the resulting alloys studied by SEM are demonstrated in Figure 2. According to the presented microscopic data, the $\text{Pt}_{1-x}\text{Ni}_x$ samples have a characteristic porous structure, which is represented by irregularly shaped primary grains 100–150 nm in size. Primary particles are accreted with each other and connected by bridges of 75–100 nm in size (Figure 2a,c,e), thus forming a single spongy structure of the alloy. At the same time, certain differences can be noted for samples with a high content of Ni (more than 50 at.%). During reductive thermolysis, sintering of the particles with increased nickel content proceeds faster due to the higher diffusion rate of Ni atoms and is less refractory if compared to platinum. As a result, a porous structure built of primary particles of a larger size (up to 200 nm) is formed (Figure 2a–d). It should be emphasized that the observed morphology is typical for porous alloys obtained by the thermolysis of precursors [47,48]. Note that the specific surface area (SSA) of the initial microdispersed alloys is averaged to be $\sim 10 \text{ m}^2/\text{g}$.

2.2. Preparation of $Pt_{1-x}Ni_x$ /CNF Composites via Ethylene Decomposition over $Pt_{1-x}Ni_x$ Alloys

In order to synthesize metal/CNF composite materials, catalytic decomposition of various hydrocarbons can be utilized [49,50]. In the present study, the synthesis of $Pt_{1-x}Ni_x$ /CNF composites was carried out via ethylene decomposition over the prepared porous $Pt_{1-x}Ni_x$ alloys. The choice of ethylene was due to its high tendency to form carbon under such reaction conditions. The overall reaction can be described by Equation (1):

The process of catalytic decomposition of hydrocarbons with the CNF formation proceeds over the dispersed particles of metallic nickel and its alloys in accordance with the carbide cycle mechanism [51]. In turn, dispersed Ni-containing particles of submicron size emerge under the action of the reaction mixture as a result of the spontaneous disintegration of the initial alloy [52,53]. Such self-dispersion of the bulk metal or alloy is due to the process of carbon erosion (CE) (also known as metal dusting [41]). Figure 3 shows schematically the CE stage.

Figure 3. Schematic illustration of the CE process: (I)—catalytic decomposition of C_2H_4 , transfer, and diffusion of carbon into the volume of the alloy; (II)—nucleation of the carbon phase at the grain boundaries; (III)—the disintegration of the alloy with the formation of active particles catalyzing the growth of CNF.

At the first stage of CE (Figure 3, stage I), ethylene molecules adsorb over the metal surface and decompose. This stage is accompanied by the transfer of carbon atoms into the alloy volume. An intensive dissolution of carbon in the metal grains results in the formation of a supersaturated carbon solution. At the next stage of the process (Figure 3, stage II), the nuclei of the graphite-like phase appear near the grain boundaries. Further accumulation of the graphite-like material leads to the disintegration of the alloy with the formation of dispersed particles catalyzing the growth of nanostructured carbon filaments (Figure 3, stage III). Depending on the reaction conditions, the alloy composition, and

its dispersity (grain size), the duration of the CE process ranges from one minute [54] to several hours [53,55] or even months [56]. At the same time, the rate of the CE process is mostly determined by the nature of the catalyst precursor and its dispersity. Thus, for the items made of bulk metals and alloys (wire, foil, etc.), which possess a small specific surface, the CE process proceeds with the lowest rate [53,55,56]. Contrarily, the use of microdispersed alloys makes it possible to accelerate the disintegration process significantly [54], which is due to an increased contact area of the metal surface with a carbon-containing reaction medium.

At the end of the CE process (Figure 3, stage III), the complete disintegration of the initial alloy leads to the formation of a large number of active particles responsible for the subsequent growth of carbon filaments via the carbide cycle mechanism. The dispersed alloy particles obtained in such a way are embedded within the structure of CNF, which prevents their sintering or mechanical entrainment. The efficiency and success of the described approach in the targeted synthesis of carbon nanomaterials and metal–carbon composites have been well reported [40,57,58]. According to our previous evaluations [54], about 10^{13} active particles of submicron size (100–300 nm) are formed from 1 g of nickel-based alloy.

As shown above, the synthesized $Pt_{1-x}Ni_x$ alloys are characterized by a well-developed porous structure, which makes it possible to provide an appropriate contact area of the alloy with the reaction mixture. Therefore, the process of controlled CE was chosen for the synthesis of $Pt_{1-x}Ni_x$ /CNF composites.

In the next step of the research, the catalytic activity of $Pt_{1-x}Ni_x$ alloys in the reaction of ethylene decomposition with the production of CNF was compared. In order to rank the samples by activity, the catalytic experiments were carried out with the same duration of 15 min. Each sample of the alloys was examined twice to check the reproducibility of the results. The obtained dependence of the carbon yield (Y_{CNF}) in the ethylene decomposition reaction on the Ni content is presented in Figure 4.

Figure 4. Dependence of the carbon yield (Y_{CNF}) in the ethylene decomposition reaction on the Ni content (at.%) in $Pt_{1-x}Ni_x$ alloy. Data for the $Ni_{1.00}$ and $Pt_{1.00}$ samples are given for comparison. The reaction conditions are as follows: $C_2H_4/H_2/Ar$, $T = 600\text{ }^{\circ}C$, 15 min.

As it follows from experimental data, pure Pt is not active in the ethylene decomposition reaction (~ 0 g/g_{cat}), which is quite expected [40]. As a result of the interaction of the Pt_{1.00} sample with ethylene, only a small layer of non-catalytic carbon is formed on its surface [40]. The inertness of platinum can be attributed to the fact that, at the reaction temperature of 600 °C, Pt does not form solid solutions with carbon [59]. Thereby, the bulk Pt does not undergo disintegration via the CE route. The addition of 30 at.% Ni to platinum does not change the situation, and the carbon yield value remains close to 0 g/g_{cat}. Comparing the obtained data with those for Pt_{1-x}Co_x bimetallic system [40], it can be noted that the Pt_{0.75}Co_{0.25} sample with the same content of base metal also exhibited low activity (the carbon yield did not exceed 1–2 g/g_{cat}).

As can be seen from Figure 4, a further increase in the Ni concentration in the Pt_{1-x}Ni_x alloy (up to 50 at.% and above) improves the catalytic activity significantly (the carbon yield exceeds 10 g/g_{cat}). The highest carbon yield of 31 g/g_{cat} was achieved over the pure Ni sample (Ni_{1.00}). This result is also not surprising. As is known, Ni belongs to the iron subgroup (Fe, Co, Ni). All these metals possess high activity in the process under study. They are traditionally used as components of the catalysts for the synthesis of carbon nanostructures by the CCVD method [60].

According to the low-temperature N₂ adsorption–desorption data, the obtained Pt_{1-x}Ni_x/CNF composites are characterized by high SSA values. Moreover, an increase in the Ni content in the alloy composition from 30 to 70 at.% leads to a rise in the SSA values from 100 to 147 m²/g.

Then, a set of Pt_{1-x}Ni_x/CNF composite samples for electrocatalytic testing in the hydrogen evolution reaction (HER) was prepared. The duration of the CCVD procedures was varied in a range from 3 to 15 min in order to provide the carbon yield of ~ 4 g/g_{cat}. At this value, the content of metals in the Pt_{1-x}Ni_x/CNF composites corresponds to 20 wt.%. In practice, according to the element analysis data (AES), the total content of metals in the composition of the synthesized composite samples is in the range of 18–22 wt.%. Table 2 summarizes the synthesis parameters and the main characteristics of the prepared Pt_{1-x}Ni_x/CNF composite samples.

Table 2. Synthesis parameters for Pt_{1-x}Ni_x/CNF composites and their characteristics.

Initial Alloy	Ethylene Decomposition Reaction Time, min	Carbon Yield, g/g _{cat}	Total Metal Content in Pt _{1-x} Ni _x /CNF Composite, wt. %	Lattice Parameter of the Initial Alloy, Å	Lattice Parameter of the Alloy after the Reaction, Å
Pt _{0.10} Ni _{0.90}	3	4.3	19	3.575 (2)	3.58 (1)
Pt _{0.20} Ni _{0.80}	4	4.3	19	3.619 (2)	3.62 (1)
Pt _{0.40} Ni _{0.60}	5	4.5	18	3.708 (2)	3.70 (1)
Pt _{0.50} Ni _{0.50}	15	3.6	22	$a = 2.690$ (2) $c = 3.617$ (2)	$a = 2.69$ (1) $c = 3.62$ (1)

The phase composition of the prepared samples of Pt_{1-x}Ni_x/CNF ($x = 0.50$ – 0.90) composites was studied by XRD (Figure 5). In most cases, the XRD patterns show reflections corresponding to Pt_{1-x}Ni_x alloys with the *fcc* structure. For the Pt_{0.50}Ni_{0.50}/CNF sample, the PtNi intermetallic compound structure was identified. As follows from Table 2, the lattice parameters of solid solutions before and after the reaction with ethylene are the same within the error of determination. Thus, the composition of the alloy particles in the composite samples corresponds to that of the initial alloys. The width of the reflections of solid solutions in the Pt_{1-x}Ni_x/CNF samples slightly increased compared to the width of the reflections of the original porous alloys. This could be caused by the incorporation of carbon into the structure of the alloy particles and the occurrence of defects, which was previously observed on Pt–Ni alloys for the reaction of 1,2-dichloroethane decomposition [42]. Additionally, for all samples, the presence of a characteristic broadened peak at $2\theta = 26^\circ$, corresponding to the (002) reflection of a graphite-like material, is noted.

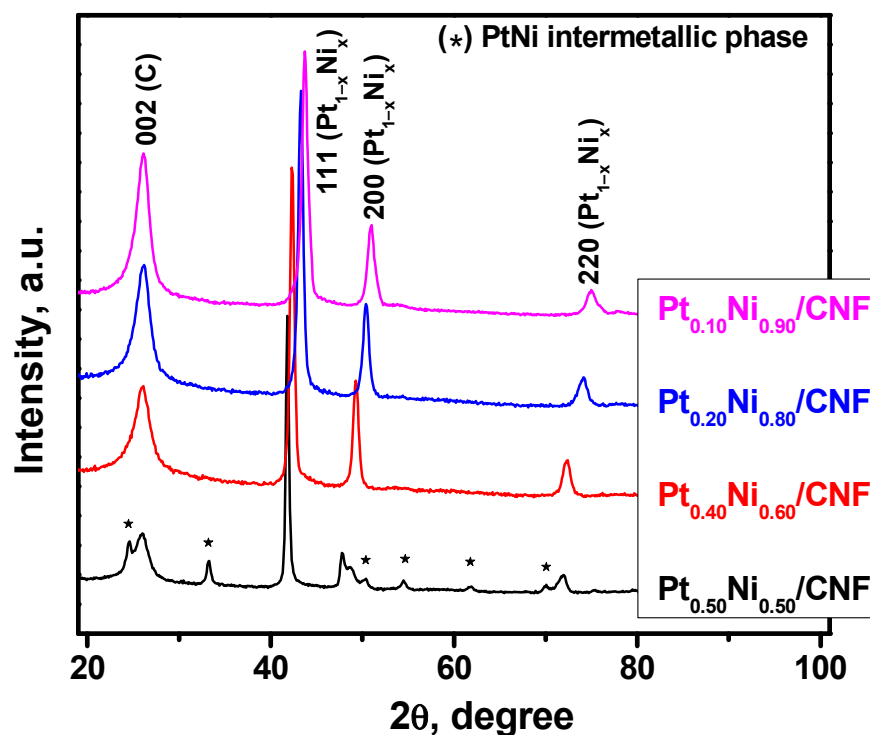

Figure 5. XRD patterns of $\text{Pt}_{1-x}\text{Ni}_x/\text{CNF}$ composites synthesized via ethylene decomposition over the respective alloys. Asterisks (*) show the superstructural reflections of the PtNi intermetallic phase.

Electron microscopy techniques, SEM and TEM, were used to study the morphology and structural features of the prepared $\text{Pt}_{1-x}\text{Ni}_x/\text{CNF}$ composite samples in detail. According to the data obtained (Figures 6 and 7), the carbon product is represented by a set of filaments of submicron diameter. Based on the array of recorded images, it can be concluded that the dispersed submicron particles were formed as a result of the disintegration of the initial alloy. These particles are clearly seen in the back-scattered electron mode (Figure 6). At a higher magnification (Figure 6b,c), it becomes evident that these metal particles behave as catalytic centers for the growth of carbon filaments. The length of the formed fibers ranges from 1 to 10 μm . Additionally, it is worth mentioning that, in certain areas of the catalyst, the disintegration of the alloy was not complete. Thus, an active particle being in the process of fragmentation (separation into several independent centers of CNF growth) is observable in Figure 6b. It can be seen that individual sections on the surface of this particle work independently, which leads to the separation of the growing carbon filament into several filaments of smaller diameters. With an increase in the exposure time, it can be expected that the complete disintegration of this particle will lead to the formation of several independent centers of CNF growth [61].

Figure 6. SEM images (back-scattered electron beam mode) of $\text{Pt}_{0.50}\text{Ni}_{0.50}/\text{CNF}$ composite obtained via ethylene decomposition at 600 $^{\circ}\text{C}$ for 15 min ($Y_{\text{CNF}} = 3.6 \text{ g/g}_{\text{cat}}$): (a) 10,000 \times ; (b) 30,000 \times ; (c) 60,000 \times .

Figure 7. SEM images (back-scattered electron beam mode) of $Pt_{1-x}Ni_x/CNF$ composites obtained via ethylene decomposition at 600 °C: (a,b) $x = 0.60$, $t = 5$ min, $Y_{CNF} = 4.5$ g/g_{cat}; (c,d) $x = 0.80$, $t = 4$ min, $Y_{CNF} = 4.3$ g/g_{cat}; (e,f) $x = 0.90$, $t = 3$ min, $Y_{CNF} = 4.3$ g/g_{cat}.

It should be noted that the catalytic particles formed via the disintegration of alloys have a predominantly symmetric polyhedron shape with a very distinct faceting (Figure 6c). The observed particle shape is one of the preferred options described earlier in [51,62]. The size of dispersed metal particles averages 150 nm (Figure 6b,c) and coincides with the diameter of the growing carbon fibers (Figure 6c). According to the estimations made, on average, about 4×10^{13} catalytic particles of the indicated size are formed from 1 g of the alloy.

An analysis of the morphology of CNF samples obtained on alloys with a high Ni content (60 at.% and above) shows that, in addition to fibers with a diameter of 0.1 to 0.25 μm , the composition of the carbon product also contains thinner fibers, the diameter of which does not exceed several tens of nanometers (Figure 7b,c,f). The appearance of such nanofibers in the composition of the CNF sample is associated with the occurrence of the process of secondary disintegration of submicron catalytic particles [53]. It should be noted that the probability of secondary fragmentation of alloy particles rises with an increase in the Ni concentration in the composition of the initial alloy, as evidenced by a noticeable increase in the proportion of thin carbon filaments in the carbon nanomaterial.

Figure 8 shows the TEM results for the $\text{Pt}_{0.50}\text{Ni}_{0.50}/\text{CNF}$ and $\text{Pt}_{0.80}\text{Ni}_{0.20}/\text{CNF}$ samples. The data obtained are consistent with the SEM data. The length of carbon filaments in the composition of the $\text{Pt}_{0.50}\text{Ni}_{0.50}/\text{CNF}$ sample does not exceed $10\ \mu\text{m}$, and the diameter is in a range from 0.1 to $0.25\ \mu\text{m}$ (Figure 8a). As is also seen, the formed alloy particles are predominantly polyhedron-shaped and clear-cut (Figure 8b,c). At the same time, in the composition of the composite obtained on the $\text{Pt}_{0.20}\text{Ni}_{0.80}$ alloy, the carbon filaments are of a noticeably shorter length (no more than $5\ \mu\text{m}$) and possess a disordered structure (Figure 8d). The presence of large metal particles within the composition of the $\text{Pt}_{0.80}\text{Ni}_{0.20}/\text{CNF}$ sample indicates that the disintegration process is incomplete in this case (Figure 8d).

Figure 8. TEM images of $\text{Pt}_{1-x}\text{Ni}_x/\text{CNF}$ composites obtained via ethylene decomposition at $600\ ^\circ\text{C}$: (a–c) $x = 0.50$, $t = 15\ \text{min}$, $Y_{\text{CNF}} = 3.6\ \text{g/g}_{\text{cat}}$; (d–f) $x = 0.80$, $t = 4\ \text{min}$, $Y_{\text{CNF}} = 4.3\ \text{g/g}_{\text{cat}}$.

Comparing the structural features of carbon filaments observed for $\text{Pt}_{0.50}\text{Ni}_{0.50}/\text{CNF}$ and $\text{Pt}_{0.20}\text{Ni}_{0.80}/\text{CNF}$ alloys, it should be noted that in the first case (Figure 8b,c), the grown filaments are of a typical coaxial-conical structure (fishbone) [63]. An increase in the Ni concentration in the alloy from 50 to 80 at.% leads to a transformation of the geometry of catalytic particles with the appearance of faces, on which the growth of fibers of a stacked structure occurs. The structure of these CNFs is known as a “pile of books” or “pile of plates” (Figure 8e,f) [64,65]. For the carbon nanofibers obtained on the $\text{Pt}_{0.50}\text{Ni}_{0.50}$ alloy, the distance between graphene layers is $0.355\text{--}0.360\ \text{nm}$, while this value is $0.348\text{--}0.355\ \text{nm}$ for the CNF samples synthesized using the $\text{Pt}_{0.20}\text{Ni}_{0.80}$ alloy. Thus, with an increase in the Ni content in the composition of the alloy, a decrease in the distance between graphene layers in the structure of carbon nanofibers is observed. Nevertheless, in both cases, the measured interplanar spacing is somewhat larger than that of crystalline graphite ($0.337\ \text{nm}$).

Based on TEM data for all the studied samples, the sizes of the alloy particles correlate with the diameter of the filaments (Figure 8a,d), which is in good agreement with the data obtained by the SEM method. According to EDX data, the composition of bimetallic particles in the $\text{Pt}_{1-x}\text{Ni}_x/\text{CNF}$ composites coincides with the ratio of Pt and Ni in the original alloy (Table 3).

Table 3. EDX data for the $Pt_{1-x}Ni_x/CNF$ samples.

Sample	Composition, at.% Ni	
	Preset	EDX *
$Pt_{0.50}Ni_{0.50}/CNF$	50	49 ± 5
$Pt_{0.20}Ni_{0.80}/CNF$	80	80 ± 3

* Each value is averaged from 10 measurements.

Thus, the decomposition of ethylene is accompanied by the disintegration of the alloy with the formation of dispersed alloy particles that catalyze the growth of carbon nanofibers. When carbon yield corresponds to $\sim 4 \text{ g/g}_{cat}$, the content of the alloy in the composition of the composite varies near the value of 20 wt.%. In such a mode of controlled carbon erosion of $Pt_{1-x}Ni_x$ alloys, a series of $Pt_{1-x}Ni_x/CNF$ composites was successfully synthesized. The Pt-Ni particles of a desired ratio are strongly anchored within the resulting $Pt_{1-x}Ni_x/CNF$ composites. Such materials can be considered catalysts with improved resistance toward deactivation caused by the sintering of the particles.

It is worth noting that the surface of the alloy particles embedded with the CNF structure is accessible for the reagents, which makes it possible to use these composites as catalysts for various electrochemical reactions.

2.3. Electrocatalytic Testing of $Pt_{1-x}Ni_x/CNF$ Composites

The electrocatalytic properties of the samples of $Pt_{1-x}Ni_x/CNF$ composites were studied in the hydrogen evolution reaction (HER) in 0.100 M H_2SO_4 . The results of the experiments performed make it possible to evaluate the electrochemical activity of alloyed samples in comparison with a commercial sample (Pt/Vulcan) containing 20 wt.% Pt on a Vulcan XC-72R carbon support. Figure 9a shows current–voltage curves obtained with a linear potential sweep. The experimentally measured current is normalized to the Pt content in the samples. It can be seen that, for all samples, a significant increase in the cathode current is observed at potentials below -220 mV . The $Pt_{0.10}Ni_{0.90}/CNF$ and $Pt_{0.20}Ni_{0.80}/CNF$ samples exhibit the highest activity, which is twice that of the commercial Pt/Vulcan sample. $Pt_{0.60}Ni_{0.40}/CNF$ showed lower activity comparable with that of the Pt/Vulcan sample. The $Pt_{0.50}Ni_{0.50}/CNF$ sample was the least active.

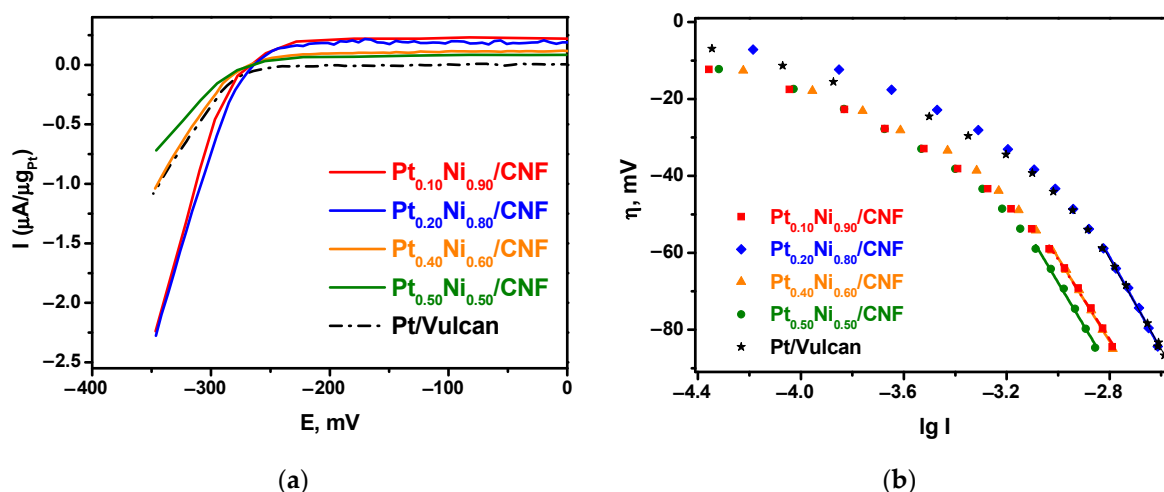

Figure 9. The catalytic activity of $Pt_{1-x}Ni_x/CNF$ composites in electrochemical hydrogen evolution reaction (HER): (a) linear potential sweep in 0.1 M H_2SO_4 at a sweep rate of 10 mV/s; (b) Tafel dependences of hydrogen evolution processes.

The Tafel dependences (Equation (2)) of hydrogen reduction processes on various samples are shown in Figure 9b.

$$\eta = a + b \cdot \lg I, \quad (2)$$

where η is the overvoltage, mV; I is the current, mA; a and b are the coefficients.

The coefficients a and b , determined by linear approximation of the graphs in the high overvoltage region, are presented in Table 4. The exchange current densities i_0 in this region for different samples have comparable values. The values of the Tafel slopes b close to 120 mV in the overvoltage region above 60 mV allow us to conclude that the rate-determining stage of the hydrogen reduction process is the same for all samples and is determined by the slow desorption of hydrogen atoms from the electrode surface [66].

Table 4. The values of the empirical constants of the Tafel equation for the $Pt_{1-x}Ni_x/CNF$ samples in comparison with the reference sample Pt/Vulcan.

Sample	$\eta = a + b \cdot \lg I$	
	a (mV)	b (mV)
$Pt_{0.10}Ni_{0.90}/CNF$	-373 ± 11	-104 ± 4
$Pt_{0.20}Ni_{0.80}/CNF$	-400 ± 10	-121 ± 4
$Pt_{0.40}Ni_{0.60}/CNF$	-387 ± 8	-109 ± 3
$Pt_{0.50}Ni_{0.50}/CNF$	-403 ± 13	-112 ± 5
Pt/Vulcan	-390 ± 8	-117 ± 3

The results of the electrochemical impedance spectroscopy analysis are presented in the Supplementary Information (Figure S1). This method was used to obtain the information concerning the kinetics of electrochemical processes over $Pt_{1-x}Ni_x/CNF$ composites. Comparison of the presented Nyquist plots testifies that the charge transfer resistance (R_{CT}) for the $Pt_{1-x}Ni_x/CNF$ samples is somewhat lower than that for the commercial sample (Pt/Vulcan). The estimation of the radii values from the Nyquist plots gives $R = 22.88$ Ohm for $Pt_{0.20}Ni_{0.80}/CNF$, $R = 19.9$ Ohm for $Pt_{0.10}Ni_{0.90}/CNF$, and $R = 25.5$ Ohm for Pt/Vulcan. As is known, the electrocatalytic activity is connected with the R_{CT} value. Thereby, the resulting $Pt_{1-x}Ni_x/CNF$ catalysts are more active in the electrochemical hydrogen evolution reaction than the Pt/Vulcan reference sample. The data obtained expand the possibilities of using the solid-state reaction products of the hydrocarbon decomposition over porous alloys for electrocatalytic applications. Reducing the platinum loading in the catalyst composition allows for reducing the cost while maintaining its efficiency.

3. Materials and Methods

3.1. Materials and Chemicals

$[Pt(NH_3)_4]Cl_2 \cdot H_2O$ (Aurat, Moscow, Russia), $[Ni(NH_3)_6]Cl_2$ (synthesized according to a well-known method [67]), ammonia (puriss. spec.), acetone (puriss. spec.), and helium (puriss. spec.) were used to prepare $Pt_{1-x}Ni_x$ alloys. Hydrogen was obtained using a Tsvetkhrom-6 generator (Tsvetkhrom, Dzerzhinsk, Russia). Hydrochloric acid (puriss. spec.) and nitric acid (puriss. spec.) were used to prepare the samples for elemental analysis.

High-purity ethylene purchased from Nizhnekamskneftekhim (Nizhnekamsk, Russia), high-purity argon, and hydrogen were used for the synthesis of $Pt_{1-x}Ni_x/CNF$ composites.

Bidistilled water, isopropanol (puriss. spec.), Nafion (Sigma-Aldrich, Burlington, MA, USA), high-purity argon, and sulfuric acid (puriss. spec.) were used in the electrochemical experiments. The reference sample, 20% Pt/Vulcan XC-72R, was purchased from Sigma-Aldrich (Burlington, MA, USA).

3.2. Synthesis of $Pt_{1-x}Ni_x$ Alloys

The samples of initial alloys were obtained by thermolysis of specially prepared precursors, which were micro-heterogeneous mixtures of platinum and nickel amino complexes. The complex salts $[Pt(NH_3)_4]Cl_2 \cdot H_2O$ and $[Ni(NH_3)_6]Cl_2$ were used as initial metal compounds. Weighed portions of complex compounds taken in the required ratios (500 mg in total) were dissolved in 4–6 mL of ~10% aqueous ammonia solution. The resulting solution was quickly added to 100–120 mL of chilled acetone with vigorous

stirring. The precipitate was filtered out, washed with acetone, and dried in air. The thermolysis procedure of the resulting precursor was carried out in a quartz reactor in an H_2 atmosphere at $600\text{ }^{\circ}\text{C}$ for 1 h. Then, the sample was cooled to room temperature in a helium flow. Thermolysis of the precursor containing 50 at.% Ni was carried out for 3 h to obtain alloy particles with the crystal structure of the PtNi intermetallic compound. Monometallic reference samples, $Pt_{1.00}$ and $Ni_{1.00}$, were also synthesized using the same procedures.

3.3. Synthesis of $Pt_{1-x}Ni_x$ /CNF Composites

Synthesis of $Pt_{1-x}Ni_x$ /CNF composites was performed in a horizontal quartz flow reactor, shown in Figure 10. A specimen of the alloy (catalyst precursor) was placed on a quartz plate in an amount of $25.00 \pm 0.02\text{ mg}$. Then, the plate was loaded into a reactor (Zhengzhou Brother Furnace Co., Ltd., Zhengzhou, Henan, China) in a horizontal position. Note that the furnace of the reactor is characterized by a uniform temperature profile along its length ($\pm 5\text{ }^{\circ}\text{C}$). Next, the sample was heated in an inert gas (Ar) flow to the reaction temperature ($600\text{ }^{\circ}\text{C}$), after which the sample was preliminarily reduced in an H_2 flow (for 15 min) in order to remove the surface oxide film. Then, at the same temperature, the reactor was fed with a reaction mixture containing 40 vol.% C_2H_4 , 20 vol.% H_2 , and 40 vol.% Ar. The feed rate of the reaction mixture was 54 L/h. Upon completion of the reaction, the obtained $Pt_{1-x}Ni_x$ /CNF composites were cooled in an argon flow and then unloaded from the reactor. After weighing the sample, the carbon yield (Y_{CNF} , g/g_{cat}) was calculated. Each experiment was repeated at least two times to refine the data on the catalytic activity of the alloys. The measurement error for the calculated carbon yield did not exceed 10%.

Figure 10. Scheme of the experimental setup used for the synthesis of $Pt_{1-x}Ni_x$ /CNF composites: 1—quartz plate; 2—sample of $Pt_{1-x}Ni_x$ alloy; 3—gas vessels; 4—tubular quartz reactor; 5—heating elements; 6—input of the reaction mixture ($C_2H_4/H_2/Ar$); 7—output of reaction gases; 8—resulting $Pt_{1-x}Ni_x$ /CNF composite.

3.4. Characterization of Materials

The elemental composition of the $Pt_{1-x}Ni_x$ alloys was determined by inductively coupled plasma atomic emission spectrometry (ICP-AES) on a Thermo Scientific iCAP-6500 spectrometer (Thermo Fisher Scientific, Waltham, MA, USA). Before analysis, the

samples were dissolved in aqua regia at heating. The relative standard deviation of the determination of metals was 0.03.

Powder X-ray diffraction (XRD) analysis of the samples was carried out on a Shimadzu XRD-7000 diffractometer (Shimadzu Corporation, Tokyo, Japan) at $\text{CuK}\alpha$ radiation, using a graphite monochromator. The patterns were recorded within a 2θ angle range of $20\text{--}100^\circ$ with a step of 0.05° .

The specific surface area values were measured by nitrogen adsorption at 77 K. The isotherms were recorded using an automatic adsorption analyzer 3P sync 220A (3P INSTRUMENTS, Odelzhausen, Germany). Before the measurements, all samples were degassed in a vacuum of less than 1 Pa at 300°C for 3 h.

The identification of the crystalline phases was based on the ICDD powder diffraction file cards [44]. The unit cell parameters were determined by the full profile method using the specified software [68]. The composition of the phases in the alloys was determined from diffraction data using the calibration dependence of the specific atomic volume of the alloy on the composition in accordance with Equation (3) [45].

$$v = V_{\text{cells}} / Z_{\text{at}}, \quad (3)$$

where v is the specific atomic volume of the alloy (the average volume occupied by one metal atom), V_{cell} is the volume of the crystalline cell of the alloy, and Z_{at} is the number of metal atoms per cell.

The study of the secondary structure and morphology of the samples of alloys and carbon material was carried out by scanning electron microscopy (SEM) on a JSM-5100LV microscope (JEOL Ltd., Tokyo, Japan) equipped with an EX-23000BU EMF spectrometer (SPECTRO Analytical Instruments, Kleve, German). The working voltage of the microscope was 15 kV, and the magnification was in a range of $1000\text{--}100,000\times$.

The study of the primary structure and composition of carbon product samples was performed by transmission electron microscopy (TEM) on a JEOL JEM 2100 instrument (JEOL Ltd., Tokyo, Japan) equipped with an INCA-250 energy dispersive x-ray spectrometer (Oxford Instruments, Abingdon, Oxfordshire, UK). The accelerating voltage was 200 kV, and the resolution was 0.14 nm. The samples were applied to perforated carbon films fixed on a copper grid. Computer processing of the obtained EM images and measuring the distances between the layers of graphene in the structure of carbon nanofibers were performed using the Digital Micrograph “Gatan” (Pleasanton, CA, USA).

3.5. Electrochemical Testing of $\text{Pt}_{1-x}\text{Ni}_x/\text{CNF}$ Composites

The synthesized samples of $\text{Pt}_{1-x}\text{Ni}_x/\text{CNF}$ composites were tested in the hydrogen evolution reaction (HER). A glassy carbon electrode (Sigradur G brand, HTW Hochttemperatur-Werkstoff GmbH, Thierhaupten, Germany) was used as a working electrode (working surface diameter 5.00 mm, geometric working area 0.196 cm^2). To modify the electrode with $\text{Pt}_{1-x}\text{Ni}_x/\text{CNF}$ composite samples, a suspension of the following composition was prepared: 5.00 mg of the sample, 1000 μL of isopropyl alcohol, 900 μL of bidistilled water, and 100 μL of 10% Nafion. This mixture was processed in an ultrasonic bath (Vilitek VBS-2DS, Vilitek, Moscow, Russia) at a frequency of 40 kHz (15 min), and then at a frequency of 28 kHz (15 min). After that, using a Lenpipet Digital Micro 0.5–10 μL automatic pipette (Lenpipet, Moscow, Russia), 5.00 μL of the suspension was applied to the prepared glassy carbon electrode and dried for 15 min in an argon flow.

The electrochemical measurements were carried out on a P-20X8 potentiostat (Elins, Novosibirsk, Russia) in a homemade three-electrode cell at room temperature. A platinum grid was used as a counter electrode. The working solution and space for the counter electrode were separated by a filter with a pore size of $0.4\text{ }\mu\text{m}$ (Sartorius AG, Göttingen, Germany). The reference electrode was a silver chloride electrode $\text{Ag} \mid \text{AgCl} \mid 3.5\text{ M KCl}$ (Izmeritelnaya Tehnika, Moscow, Russia) with a potential of 208 mV regarding the normal hydrogen electrode. The reference electrode was connected to the working solution using a Luggin capillary filled with a working electrolyte. To study the hydrogen evolution

reaction (HER), the cell was filled with a solution of 0.1 M H₂SO₄ (approximately 50 mL), and the solution was purged with argon for 20 min. After that, a cyclic potential sweep was performed: 50 cycles at 50 mV/s in a range of −350–1000 mV to standardize the surface of the working electrode. Then, the solution was purged with hydrogen for 20 min, and voltammetric measurements were performed with a linear potential sweep in the range from 500 to −350 mV at a potential sweep rate of 10 mV/s. During the experiments, the working solution was stirred on an IKA Topolino (IKA-Werke GmbH & Co. KG, Staufen, Germany) magnetic stirrer.

The electrochemical impedance spectroscopy measurements were carried out on a SP-300 Potentiostat (Bio-Logic SAS, Seyssinet-Pariset, France). The EIS measurements were performed over a frequency range of 1 Hz to ~1 MHz at a perturbation amplitude of 5 mV. Nyquist plots of the catalysts in 0.1 M H₂SO₄ solution were obtained at a potential of −0.200 V vs. silver chloride electrode Ag|AgCl|3.5 M KCl.

4. Conclusions

A series of porous Pt_{1−x}Ni_x alloys were synthesized by thermolysis of multicomponent precursors in a wide range of concentrations ($x = 0.00$ – 1.00). The catalytic activity of the obtained alloys in the reaction of ethylene decomposition with the formation of CNF was studied. It has been established that the addition of Ni to Pt increases the activity of the alloy in terms of carbon yield by 10–30 times. Thus, the highest carbon yield of about 30 g/g_{cat} in the course of ethylene decomposition for 15 min was observed for the samples Pt_{0.10}Ni_{0.90} and Ni_{1.00}. It was demonstrated that Pt_{1−x}Ni_x alloys could be successfully used as precursors for obtaining metal–carbon composites.

Using the prepared Pt_{1−x}Ni_x alloys of desired compositions, the Pt_{1−x}Ni_x/CNF composites containing 20 wt.% of the alloy were synthesized via ethylene decomposition performed in a mode of controlled carbon erosion. The resulting Pt_{1−x}Ni_x/CNF samples represent submicron alloy particles embedded within the structure of carbon nanofibers. It was shown that the ratio of metals in these alloy particles corresponds to that in the initial alloys. The prepared composites were tested in the electrochemical hydrogen evolution reaction. The Pt_{0.10}Ni_{0.90}/CNF and Pt_{0.20}Ni_{0.80}/CNF samples demonstrate the highest activity in this process, which exceeds the performance of the commercial 20 wt.% Pt/Vulcan XC-72R sample by two times. Thus, the proposed approach to the preparation of metal–carbon composite catalysts, in which platinum is replaced by cheaper nickel by up to 80%, provides the possibility of significantly reducing the cost of implementing practically important electrochemical processes.
