## **SI-7. Other microfluidic devices for plasma separation**

In an effort to improve the separation process, two additional resin formulations were investigated. These, two alternative microfluidic devices were tested, which had different material properties from Device 15, but with a similar structure (see Table SI-6). The first approach involved the fabrication of a transparent device to overcome the need for the collection of the separated plasma for colorimetric analysis in Device 15 (see Section 3.6). A transparent device should allow *in situ* colorimetric analysis of the separated plasma in the device. For this purpose, Device 16 was successfully fabricated, see Table SI-6, with resin B. However, during the evaluation of this device, whole blood did not enter the sedimentation trench and plasma separation was not achieved. A possible explanation for this fact could be the chemical difference between the UV absorbers, Avo and NPS, which could give the resin different surface chemistry properties. Another possibility is that the change in UV absorber resulted in small variations in 3D printed feature dimensions or surface roughness, which could also affect flow.

For Device 17, a hydrophobic resin (resin C) was developed in the pursuit of mimicking the hydrophobic character of the barrier used in Device 15. Because this feature was important for successful sedimentation, we fabricated a hydrophobic device to test this feature for the entire device. However, we found that the blood sample did not flow into Device 17. Therefore, we concluded that, the same feature that allowed the blood cells not to stick to the top surface of the sedimentation trench and thus, a successful plasma separation, acted as an obstacle for the entrance of the whole blood to this chamber. The highly hydrophobic character of Device 17 could be the reason behind that, which hindered the blood flow, making impossible the separation of the plasma.
