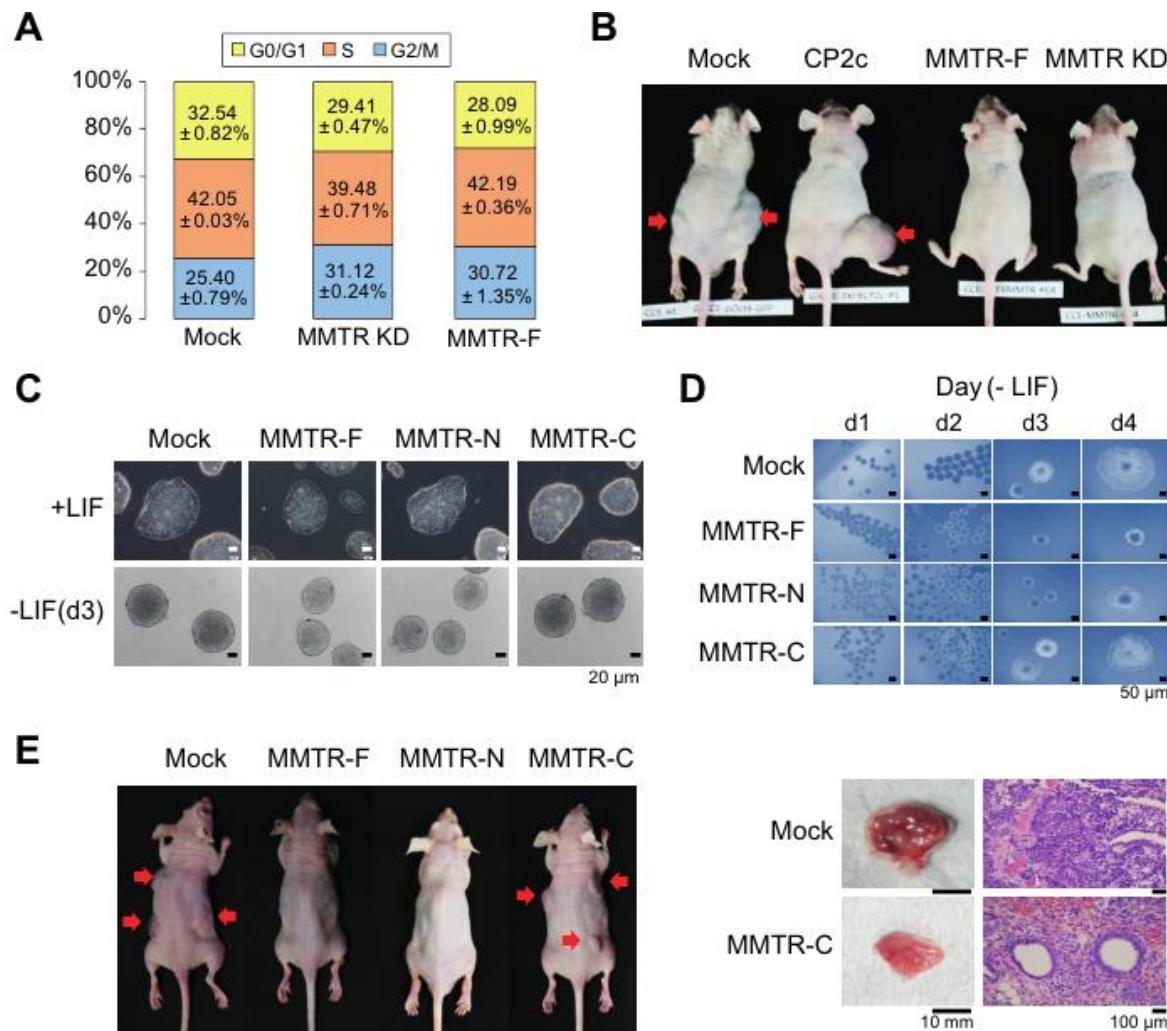

Figure S1. Establishment and characterization of MMTR mutant cell lines. (A–B) Establishment and characterization of MMTR KD and MMTR-F mESC lines. (A) Cell cycle profiles of cells cultured under LIF were analyzed by flow cytometry. (B) *In vivo* teratoma forming assays. Wild type and oncogenic CP2c-OE mESCs were as positive controls. (C–E) Establishment and characterization of MMTR-F, -N, and -C mESC lines. (C) Morphological images of colonies under phase contrast microscope and (D) EB images (embryoid body) for 4 days culture without LIF. (E) *In vivo* teratoma forming assays in mock, MMTR-F, -N and -C mESCs-injected mice (left) and teratoma lesions in mock and MMTR-C mESC injected mice (right).

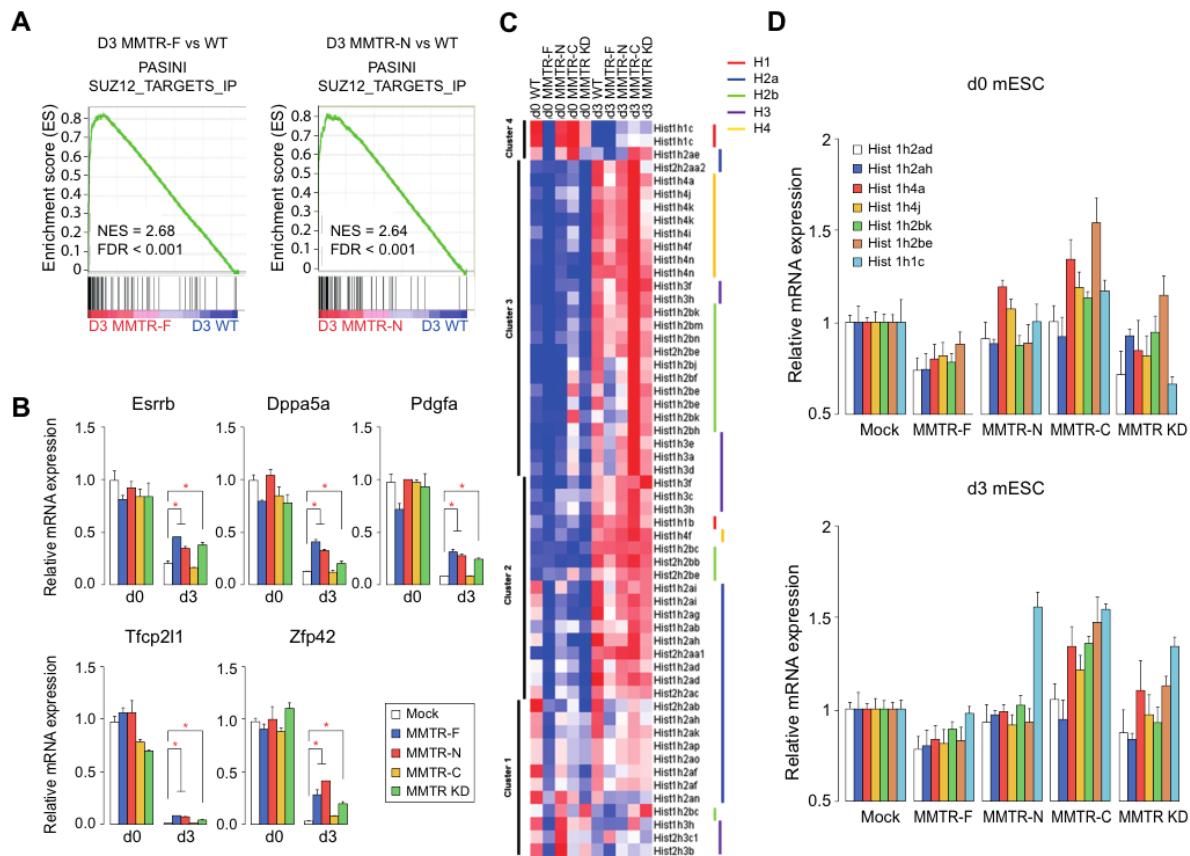

Figure S2. The contribution of MMTR/Dmap1 mutant cells and their effects on the mESC differentiation. **(A)** GSEA2 analysis of MMTR/Dmap1-full length or -N term overexpressed mESCs compared to wild type. **(B)** RT-qPCR of selected target genes from each mutant cell line under undifferentiation (d0) and differentiation condition (d3). **(C)** Heatmap showing expression levels of the histone gene cluster genes by microarray and **(D)** RT-qPCR showing expression levels of the selected histone genes in each MMTR/Dmap1 mutant at d0 and d3. $n = 2$. * $p < 0.05$.

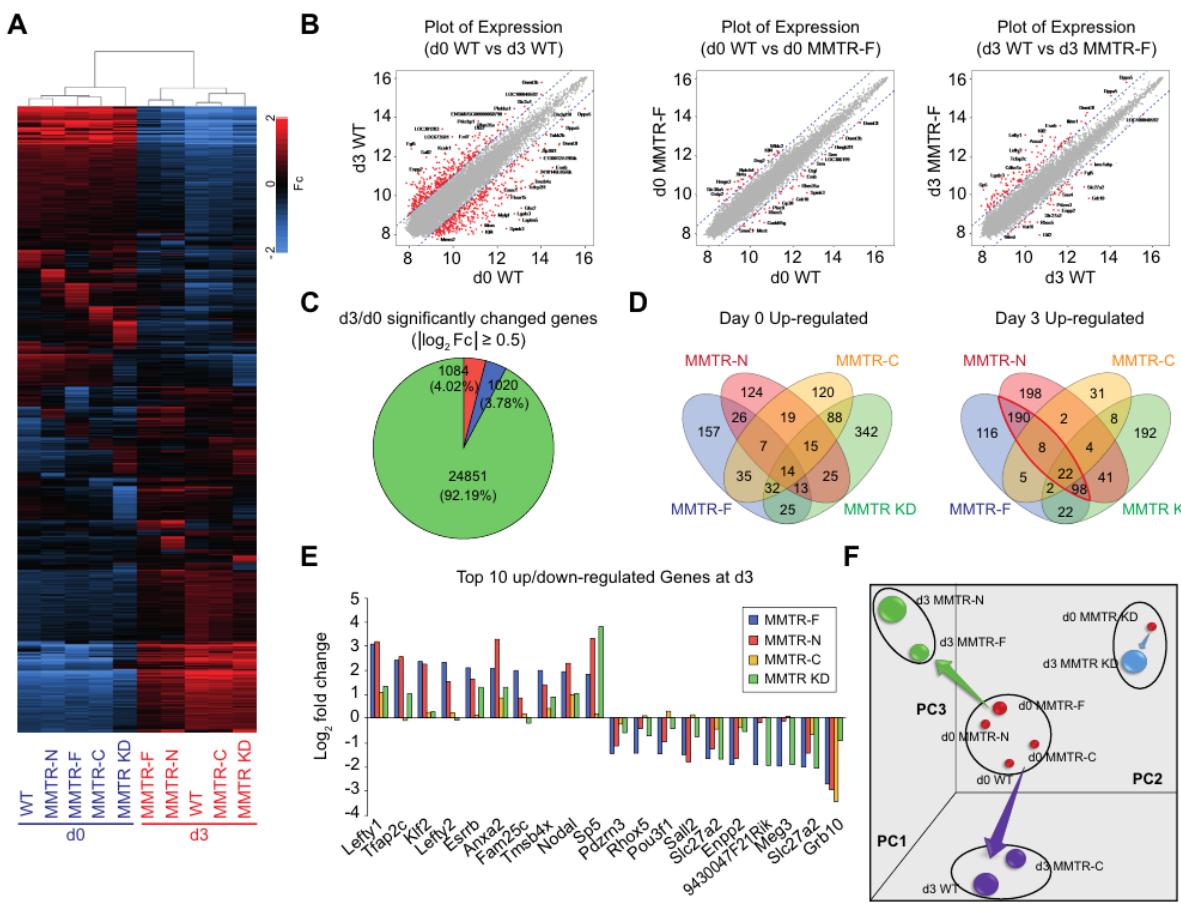

Figure S3. High throughput expression analysis of each MMTR/Dmap1 mutant cell by microarray. (A) Heat map analysis of each MMTR/Dmap1 mutant cell line on day 0 (d0) and day 3 (d3), and (B) scatter plots of datasets in wild type and MMTR/Dmap1-full length overexpressed mESCs on d0 and d3. Number of (C) preferentially expressed genes in wild type mESCs and (D) up-regulated genes in each MMTR/Dmap1 mutant cell for 3 days spontaneous differentiation. (E) RT-qPCR showing expression of selected up- or down-regulated genes in each MMTR/Dmap1 mutant cell line compared to wild type mESCs on d3. (F) Principal component analysis of gene expression in each MMTR/Dmap1 mutant cell.

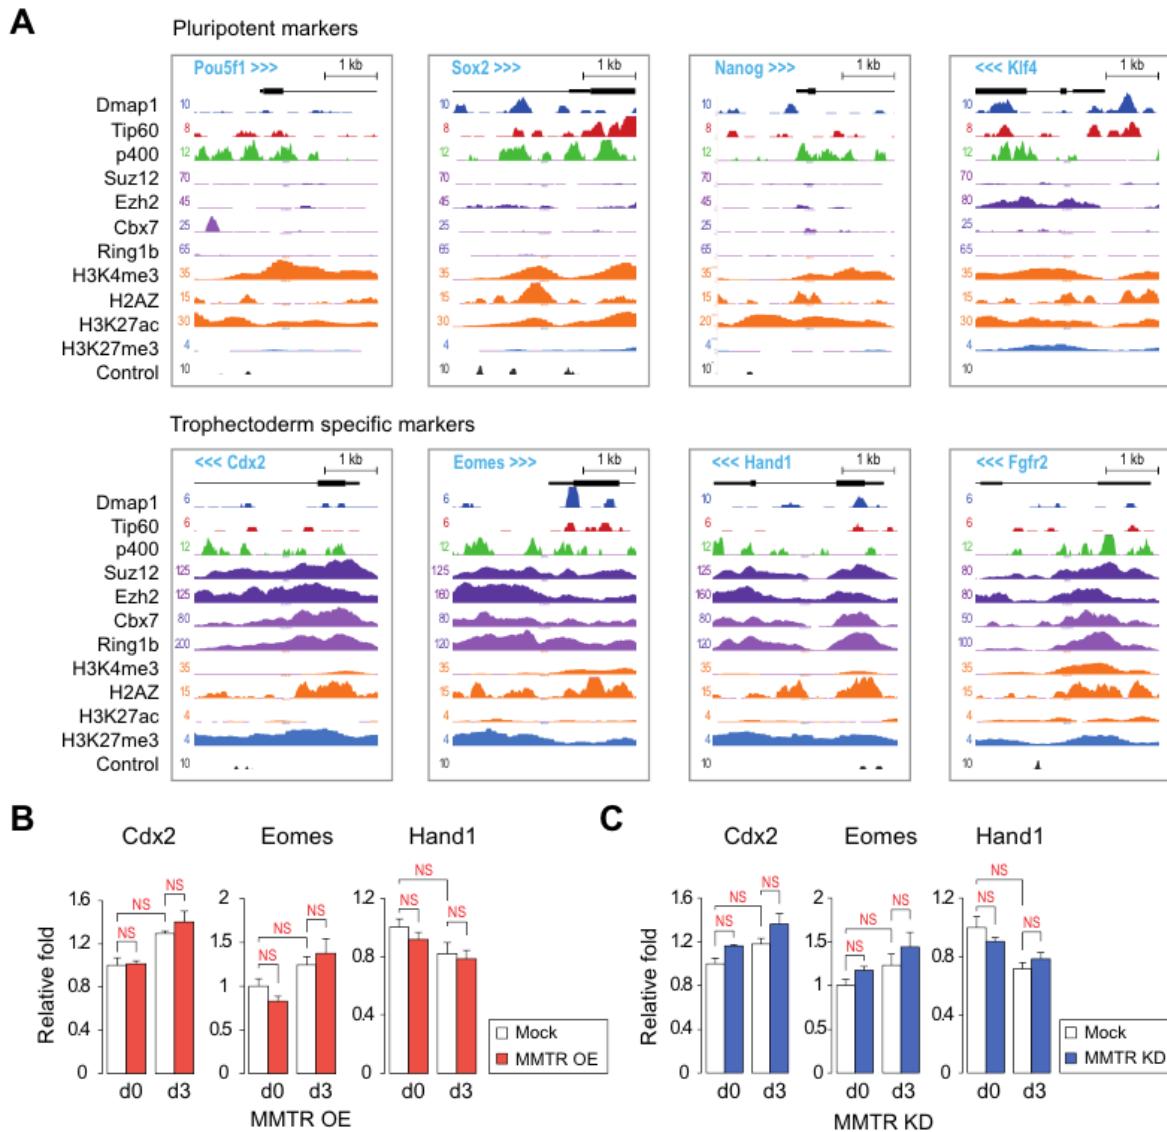

Figure S4. MMTR/Dmap1 does not regulate trophoblast marker genes. **(A)** Binding patterns of MMTR/Dmap1, Tip60-p400 complex, PRC1/2 complex, and H2A.Z, and activation or inactivation histone marks at regulatory regions including CpG islands of pluripotency or trophectoderm marker genes. **(B-C)** Trophectoderm marker gene expression profiles during maintenance or differentiation of MMTR/Dmap1-KD / OE cells by RT-qPCR. NS, no significant.

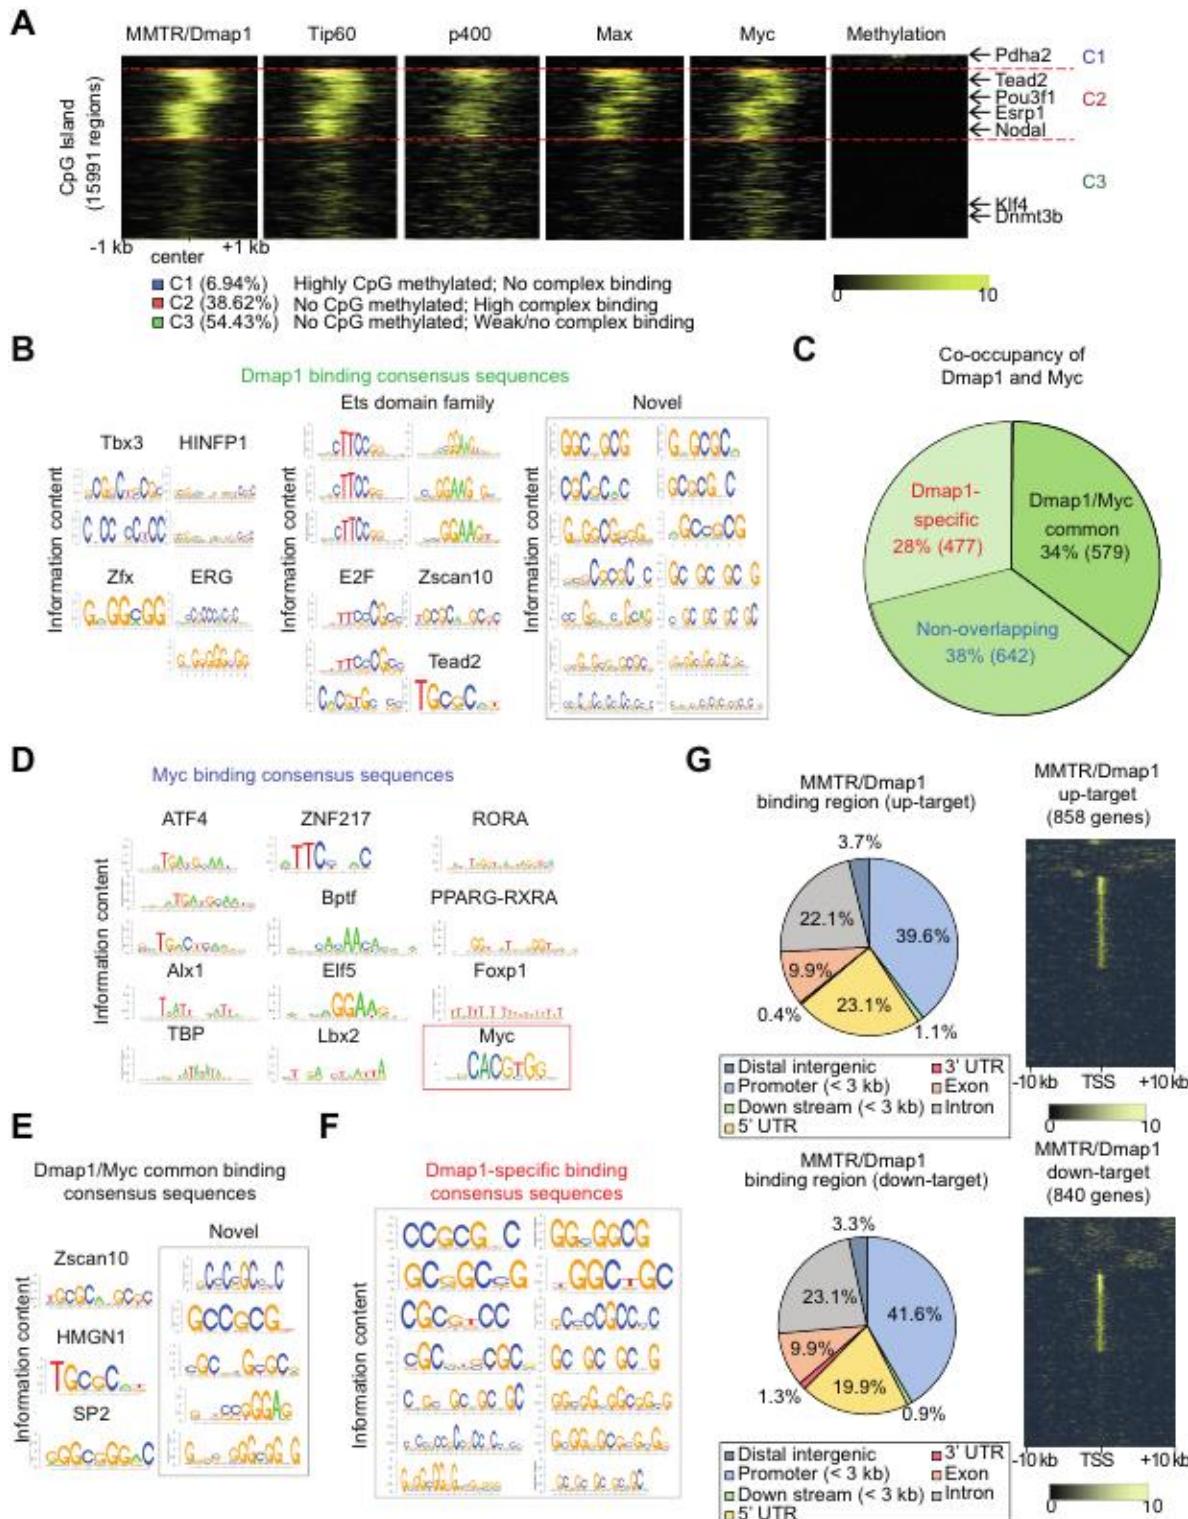

Figure S5. Tip60-p400 complex subunit MMTR/Dmap1 regulates the expression of genes involved in maintenance and differentiation of mESCs. (A) ChIP-seq heat maps of MMTR/Dmap1, Tip60, p400, Max, and Myc enrichment on the 15,991 CpG island-containing regions from -1 Kb to +1 Kb from each peak center. Heat maps are sorted by DNA methylation propensity. C1 to C3 regions represent three criteria. C1: high methylation, but no MMTR/DMAP1-Tip60-p400 complex binding (Pdha2). C2: No methylation, but high MMTR/DMAP1-Tip60-p400 complex binding (Tead2, Pou3f1, Esrp1, and Nadal). C3: No methylation as well as weak (or no) MMTR/DMAP1-Tip60-p400 complex binding (Klf4 and Dnmt3b). (B) Binding consensus sequences of MMTR/Dmap1 in TSS (-1 kb ~ +1 kb) of its 1698 target genes. Ets domain family and GC-rich sequences are enriched in MMTR/Dmap1 target genes. Tbx3, T-box transcription factor 3; HINFP1, Histone H4 transcription factor 4; Zfx, Zinc finger

protein X-linked; ERG, ETS transcription factor; Zscan10, Zinc finger and SCAN domain containing 10. (C) Co-occupancy with Myc in MMTR/Dmap1 target genes. Among 1698 target genes of MMTR/Dmap1, 579 genes (34%) are overlapped with those of Myc, and 477 genes (28%) are only MMTR/Dmap1-specific. In addition, both MMTR/Dmap1 and Myc bind to different regions of 642 genes (38%). (D) Consensus sequences of Myc binding in MMTR/Dmap1 target genes from panel (C). Myc consensus sequence is indicated by red square. ATF4, Activating transcription factor 4; ZNF217, Zinc finger protein 217; RORA, RAR related orphan receptor A; Alx1, ALX homeobox 1; Bptf, Bromodomain PHD finger transcription factor; PPARG-RXRA, Peroxisome proliferator activated receptor gamma-Retinoid X receptor alpha; Elf5, E74 like ETS transcription factor 5; Foxp1, Forkhead box P1; TBP, TATA-box binding protein; Lbx2, Ladybird homeobox 2. (E) Consensus sequences of MMTR/Dmap1 and Myc co-occupancy regions from panel (C). (F) Consensus sequences of MMTR/Dmap1-specific binding regions from panel (C). SP2, Sp2 transcription factor. (G) Distribution of MMTR/Dmap1 binding sites in the significantly up- (858, upper) and down-regulated (840, lower) gene regions (right). ChIP-seq heat maps (next to corresponding percentage distribution circle) are extending from -10 kb to +10 kb from each TSS. Each row represents a gene, and enrichment denoted in yellow. The color bars indicate binding strength.

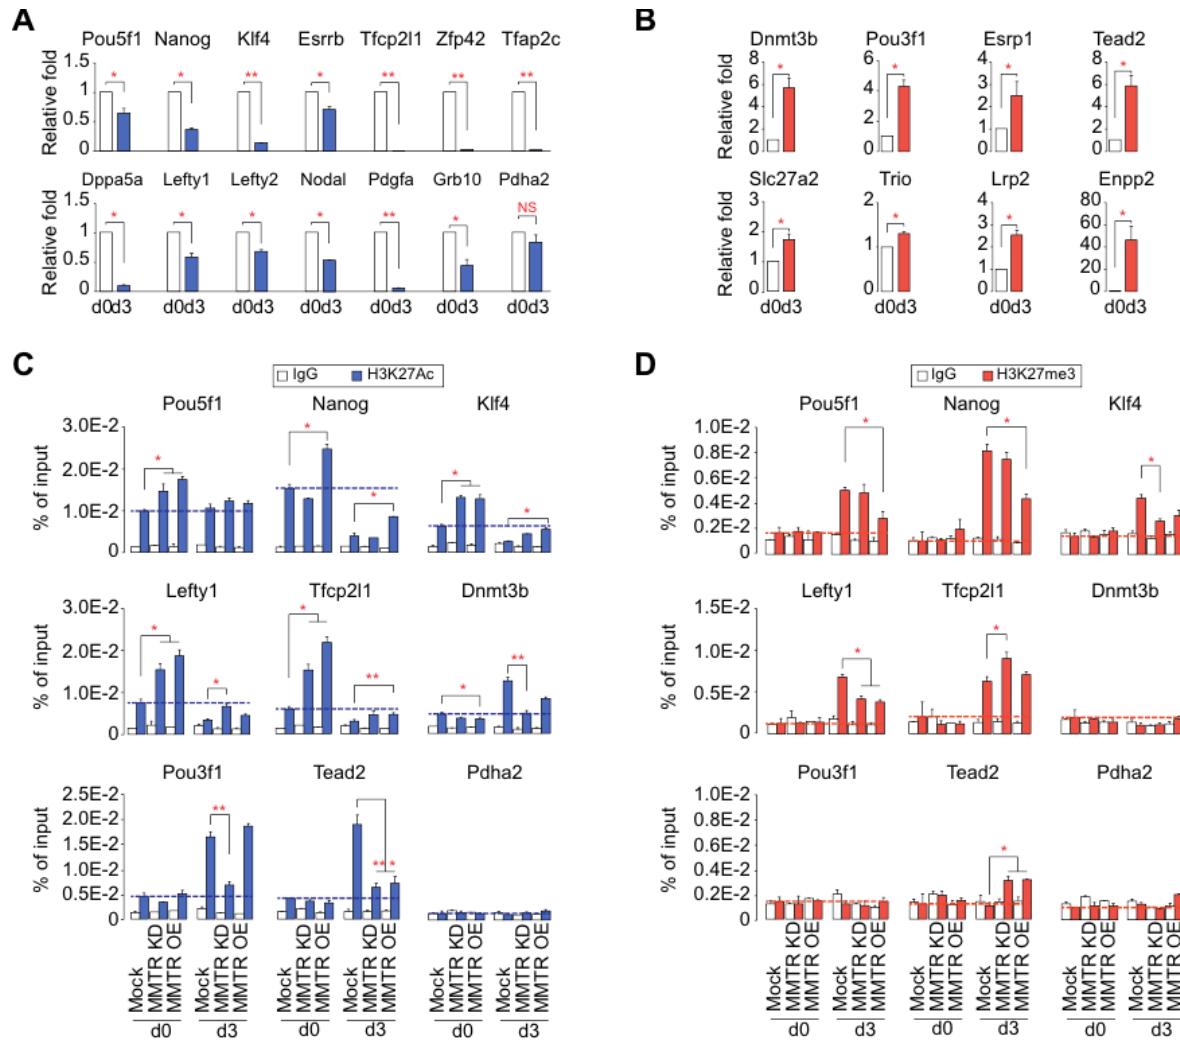

Figure S6. Differentiation dependent expression changes of selected commitment genes and MMTR/Dmap1 dependent H3K27 modification status in their promoters. (A,B) RT-qPCR graphs showing gene expression fold changes in MMTR/Dmap1 target genes (stemness genes; A, Developmental genes; B) of Figure 5A. (C,D) ChIP-qPCR graphs showing active (H3K27ac, C) and inactive (H3K27me3, D) marks at selected MMTR/Dmap1 target gene promoters in MMTR KD and OE cells of undifferentiated (d0) and differentiated (d3) mESCs. Pdha2 are used as a negative control and output values are represented as a percentage of the respective input DNA. *, $p < 0.05$; **, $p < 0.01$; NS, no significant.

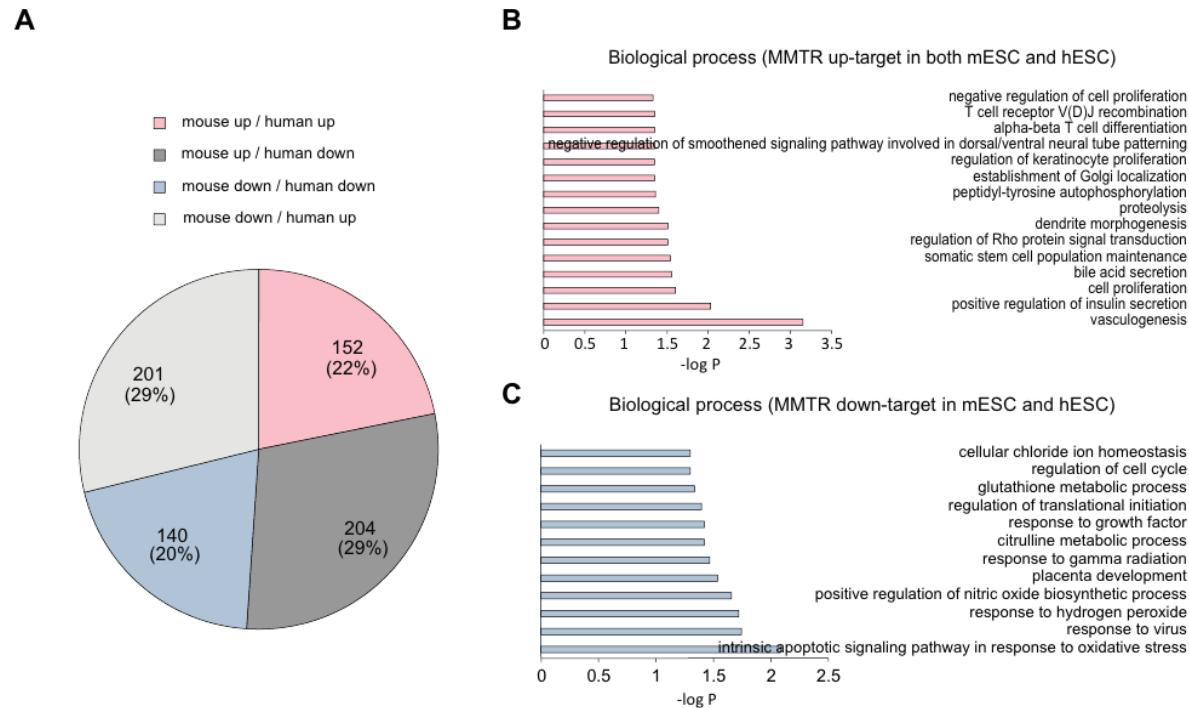

Figure S7. Comparison of MMTR/Dmap1 target genes in mouse and human ESCs. **(A)** The RNA expression profile change of hESCs differentiation (d0 and d12) (GSE15257) are compared to those of mESCs. GO term analysis of **(B)** up- or **(C)** down-regulated target genes in both mouse and human ESCs.
