

**Figure S1.** Anthocyanin biosynthesis pathway

The first stage is the phenylpropane pathway, and transforms into coumarin CoA from phenylalanine through three-step enzymatic reaction, phenylalaninammono-nialyase (PAL) as the key enzyme in this stage. The second stage, from coumarin CoA to dihydroflavonol, is the key reaction of flavonoid metabolism, the main catalytic enzymes include chalcone synthase, chalcone isomerase and Flavanone-3-hydroxylase. The third stage is the synthesis of various anthocyanins, dihydroflavonols catalyzed by flavonoid -3'-hydroxylase and flavonoid -3',5'-hydroxylase can be converted into colorless anthocyanins under the action of dihydroflavonol 4-reductase gene. At the last stage, colorless anthocyanins are catalyzed by anthocyanidinsynthase to form colored but unstable anthocyanins, and the catalytic action of UDP glucose-flavonoid- 3-o-glycosyltranferase makes anthocyanins become stable anthocyanins.

**Figure S2.** The expression vector pCAMBIA3301 is preserved by Changbai mountain characteristic plant resources research laboratory of jilin agricultural university.

**HP3 VS HC3****HP3 VS HS3****Figure S3.** Transcript\_volcano of HP3\_vs\_HC3&HP3\_vs\_HS3.

The horizontal axis is the fold-change ( $\log(B/A)$ ) value of the differential expression of the gene in different groups of samples, and the vertical axis is the statistical significance level pValue representing the change in gene expression, the smaller the pValue, the -log (pValue) The bigger the difference, the more significant the difference. Each point in the figure represents a gene in which red indicates up-regulated genes, green indicates down-regulated genes, and black indicates non-differentiated genes.
