The highest contributing factor was evaporative emissions, which accounted for 19% of the ambient VOC concentrations. This factor was dominated by high loadings of propane (56%) and moderate loadings of 2,4-dimethylpentane (31%), butane (24%), ethane (24%), 2,3-dimethylpentane (23%), and iso-butane (20%) (Figure S2). Propane, butane, and iso-butane are key markers of evaporative emission (Brown et al., 2007). According to the Texas Commission on Environmental Quality (TCEQ) report, butane, iso-butane, 2,3-dimethylpentane, and 2,4-dimethylpentane are mostly released into the air from natural gas industries (TECQ 2015; TECQ, 2016). Consequently, evaporative emissions are likely from propane and natural gas filling/storage facilities in Windsor and surrounding areas. For example, Plains Midstream Canada - Windsor Terminal, a company that transports, processes, and stores natural gas, released 53.4 tonnes of propane and 22 tonnes of butane air emissions in 2019. The company is approximately 2 km south of the Windsor monitoring station. Furthermore, residential use is another source of evaporative emissions. In Windsor, natural gas is widely used for home heating during cold seasons due to its affordable price. According to Canada Energy Regulator, 67% of households in Ontario used natural gas as the primary heating source in 2015 (CER, 2022). Some households also utilized natural gas stoves for cooking.

The second-highest contributing factor was industrial process and manufacturing, which accounted for 16% of the total ambient VOC concentrations. This factor is heavily loaded with industrial-related VOC species, such as 1,1,2,2-tetrachloroethane (77%), 1-heptene (45%), hexachlorobutadiene (45%), 1,2,4-trichlorobenzene (44%), 1,2-dichloropropane (42%), 1,1,2-trichloroethane (40%), 1,2-dichlorobenzene (40%), bromoform (39%), chloromethane (38%), and varieties of Freon (33–38%) (Figure S2). For example, 1,1,2,2-tetrachloroethane is released into the atmosphere during the manufacturing process of trichloroethylene and other chlorinated hydrocarbons (ATSDR, 2008). Hexachlorobutadiene is a by-product of the production of certain chemicals and is released into the air by using these chemicals (Government of Canada, 2007). 1,2,4-trichlorobenzene is mostly used as a solvent in textile manufacturing (Government of Canada, 2014). 1,2-dichloropropane is used as a chemical intermediate in several industries (EPA, 2000). In the US, most of the 1,2-dichloropropane released into the atmosphere was from manufacturing and processing facilities in 2018 (ATSDR, 2022). The primary sources of 1,1,2-trichloroethane emissions are the industries that manufacture it or use it in production (Australian Government, 2022). Freons are used as refrigerants and coolants in old refrigerators, car air conditioners, and other machines (Sciencing, 2023).

The third-highest contributing factor was vehicle exhaust 1, which accounted for 13% of the total ambient VOC concentrations. This factor is dominated by high loadings of MTBE (58%) and trichloroethylene (38%), and moderate loadings of ethylene (33%), acetylene (27%), and ethane (25%). MTBE is used almost exclusively as a fuel additive in motor

gasoline in the US (USEPA, 2016). MTBE released into the air is associated with leaking fuel storage tanks and unburned fuel from vehicle exhaust (Franklin et al., 2001). MTBE is commonly used as a tracer of gasoline vehicle emissions (Chen et al., 2014). In addition, the loading of ethylene, acetylene, and ethane in this study is similar to the profiles of ethylene (30%), acetylene (20%), and ethane (20%) from motor vehicle exhaust from a previous study (Baudic et al., 2016).

The sixth-highest contributing factor was gasoline storage, which accounted for 10% of the total ambient VOC concentrations. This factor is dominated by high loadings of 2,2,4-trimethylpentane (38%) and moderate loadings of 2,4-dimethylpentane (33%) and styrene (33%). 2,2,4-trimethylpentane is one of the several isomers of octane (C_8H_{18}). It is an important component of gasoline (University of Waterloo, 2016). 2,4-dimethylpentane is an isomer of heptane, which can be found in gasoline (TCEQ, 2016). The profile of 2,2,4-trimethylpentane and styrene in this study is similar to the profile of gasoline production and storage (McCarthy et al., 2013).

The fifth-highest contributing factor was vehicle exhaust 2, which accounted for 11% of the total ambient VOC concentrations. This factor is characterized by high loadings of trans-2-butene (67%), cis-2-butene (55%), and butane (45%), and moderate loadings of 2-methyl-2-butene (36%), trans-2-pentene (32%), and cis-2-pentene (27). The combustion of gasoline is a major mechanism for the release of butane into the atmosphere (TCEQ, 2015). The cis-2-butene and trans-2-butene are released into the ambient air from the combustion of fossil fuels and loss from gas plants (TCEQ, 2013). The profile of trans-2-pentene, butane, and cis-2-pentene in this study is similar to the profile of trans-2-pentene (40%), butane (30%), and cis-2-pentene (50%) in traffic-related sources (Chen et al., 2014).

The fourth-highest contributing factor was diesel exhaust, which accounted for 12% of the total ambient VOC concentrations. This factor is dominated by high loadings of trans-2-octene (100%), trans-3-methyl-2-pentene (67%), methylcyclohexane (49%), octane (43%), nonane (42%), and decane (40%), and moderate loadings of cis-2-hexene (37%), heptane (35%), and 1,2,4-trimethylbenzene (34%). Decane is abundant in diesel exhaust (Chen et al., 2019). High proportions of nonane, 1,2,4-Trimethylbenzene, and octane were reported in the USPEA source profile of diesel exhaust (profile code: 4742, USEPA, 2022).

Each of the next two factors, labelled as solvent usage and chemical process and combustion, contributed to 8% of the ambient VOC concentrations. The solvent usage factor is characterized by high loadings of 1,1-dichloroethylene (64%), toluene (48%), a-pinene (44%), d-limonene (44%), and 1,4-dichlorobenzene (39%), and moderate loadings of m and p-xylene (33%), o-xylene (31%), and ethylbenzene (30%). Dichloroethene is used as a solvent for waxes, resins, acetylcellulose, perfumes, dyes, lacquers, thermoplastics, fats, and phenols (Government of Canada, 2013). The a-pinene (44%), b-pinene (35%), and d-limonene (44%) are fragrance compounds (Lab Effects, 2023). The factor profile of toluene, ethylbenzene, and xylene in this study is similar to the profile of toluene (40%), ethylbenzene (30%), and xylene (40%) in terms of solvent usage (Baudic et al., 2016).

The chemical process and combustion factor are dominated by high loadings of trichloroethylene (56%), hexane (50%), and benzylchloride (41%), and moderate loadings of cis-3-methyl-2-pentene (38%) and methylcyclopentane (37%). Trichloroethylene is used as a solvent to remove grease from metal parts and as a chemical that is used to make chemicals. The factor profile of hexane and methylcyclopentane in this study is similar to the profile of hexane (58%) and methylcyclopentane (44%) in chemical processes (Su et al., 2019). Benzylchloride is a marker of electricity generation via combustion (NEI, 2017).

The lowest contribution factor was a biogenic source, which only accounted for 3% of the total ambient VOC concentrations. This factor is characterized by the high loading of isoprene (87%) and low loadings of b-pinene (17%), a-pinene (11%), and d-limonene (11%). Isoprene is known as a chemical marker of biogenic emissions (Baudic et al., 2016). A-pinene and b-pinene are two isomers found in nature, e.g., in pine essential oils (Salehi et al., 2019). The profile of isoprene in this study is similar to that of a biogenic source reported by Baudic et al. (2016).

It should be noted that PMF modeling may not be able to differentiate between certain factors. For example, the PMF was unable to differentiate commercial cooking as a standalone factor in this study, even though it has been noted in other recent urban studies (Wang, H. et al., 2017; Lin, X.B. et al. 2022). The proximity of measurement sites to commercial cooking districts in urban areas may play a role. Concentrations of VOC species related to commercial cooking, such as ethane and ethylene, could be reflected in some of the nine factors resolved in this study, thereby leading to overestimated contributions of other factors.

Propane	1.11E-12	Carter, 2010
Propylene	2.60E-11	Carter, 2010
Styrene	5.80E-11	Carter, 2010
Tetrachloroethylene		Not found
Toluene	5.58E-12	Carter, 2010
trans-2-Butene	6.32E-11	Carter, 2010
trans-2-Hexene	6.60E-11	Carter, 2010
trans-2-Octene	6.89E-11	Carter, 2010
trans-2-Pentene	6.70E-11	Carter, 2010
trans-3-Methyl-2-Pentene	8.85E-11	Carter, 2010
trans-4-Methyl-2-Pentene	5.98E-11	Carter, 2010
Trichloroethylene	2.34E-12	Carter, 2010
Undecane	1.23E-11	Carter, 2010
Vinylchloride	6.90E-12	Carter, 2010

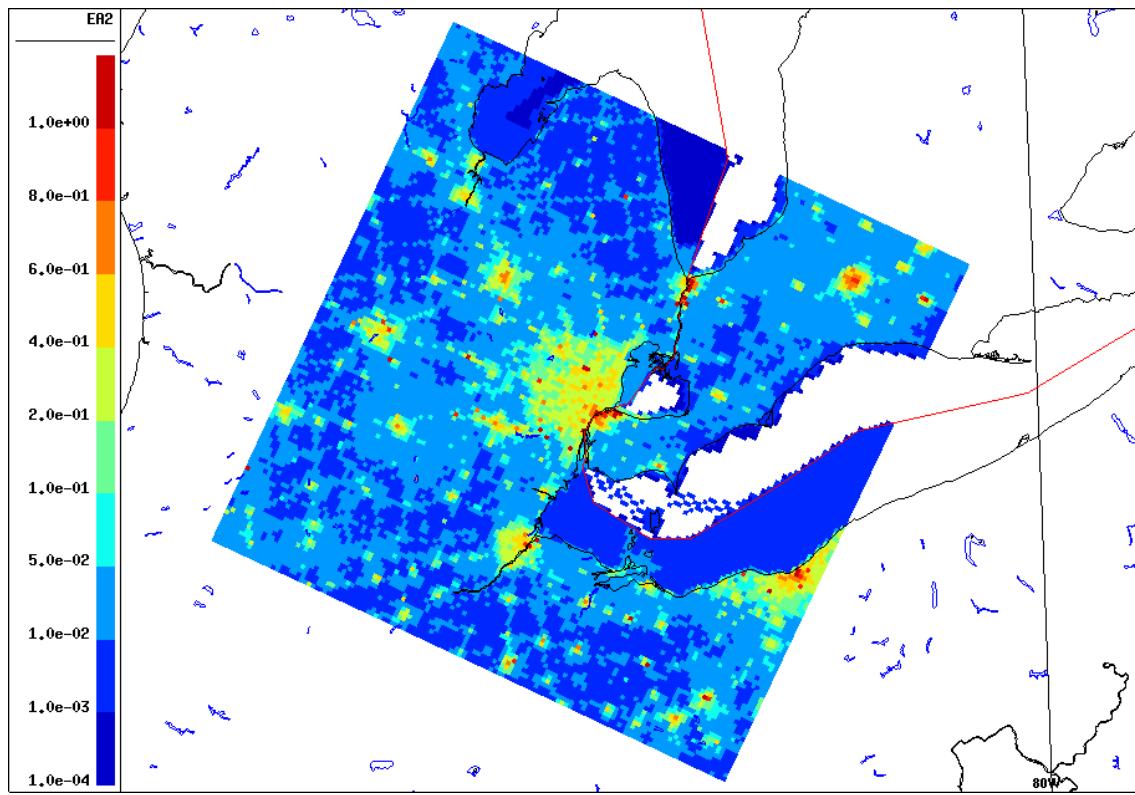

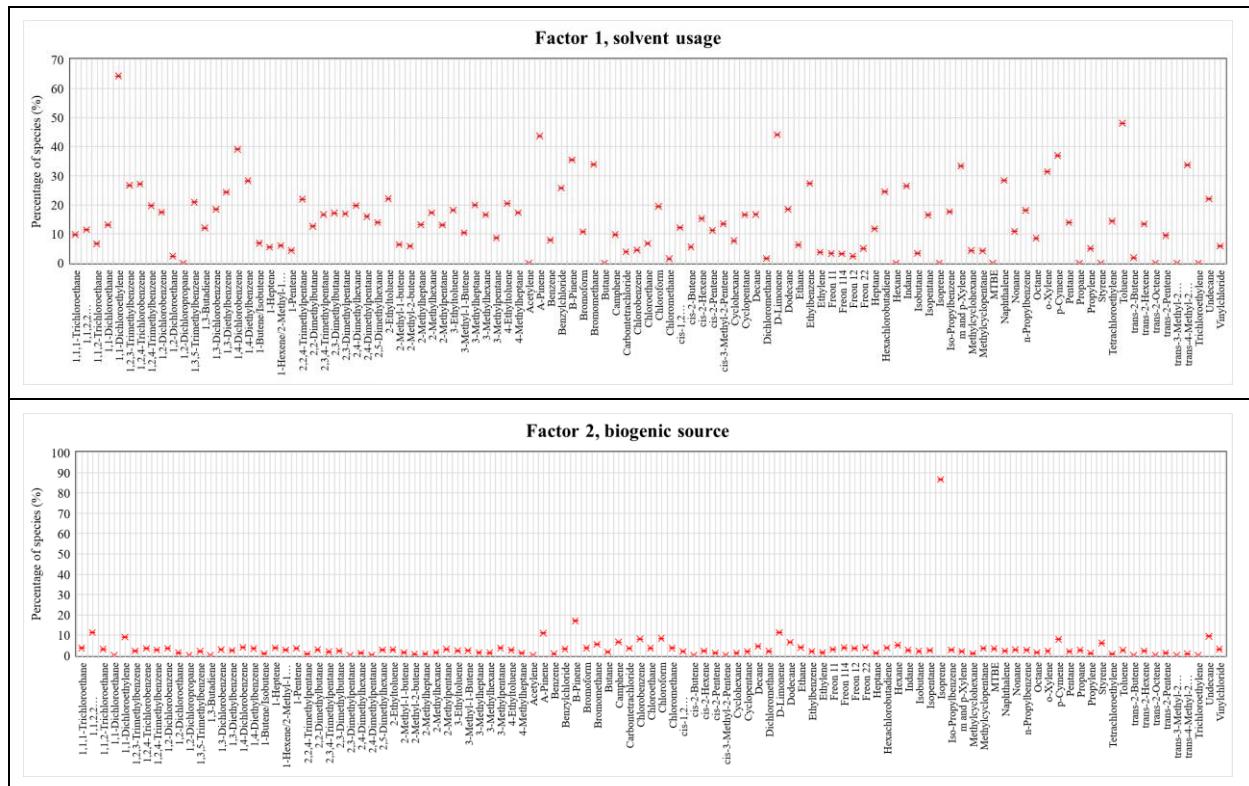

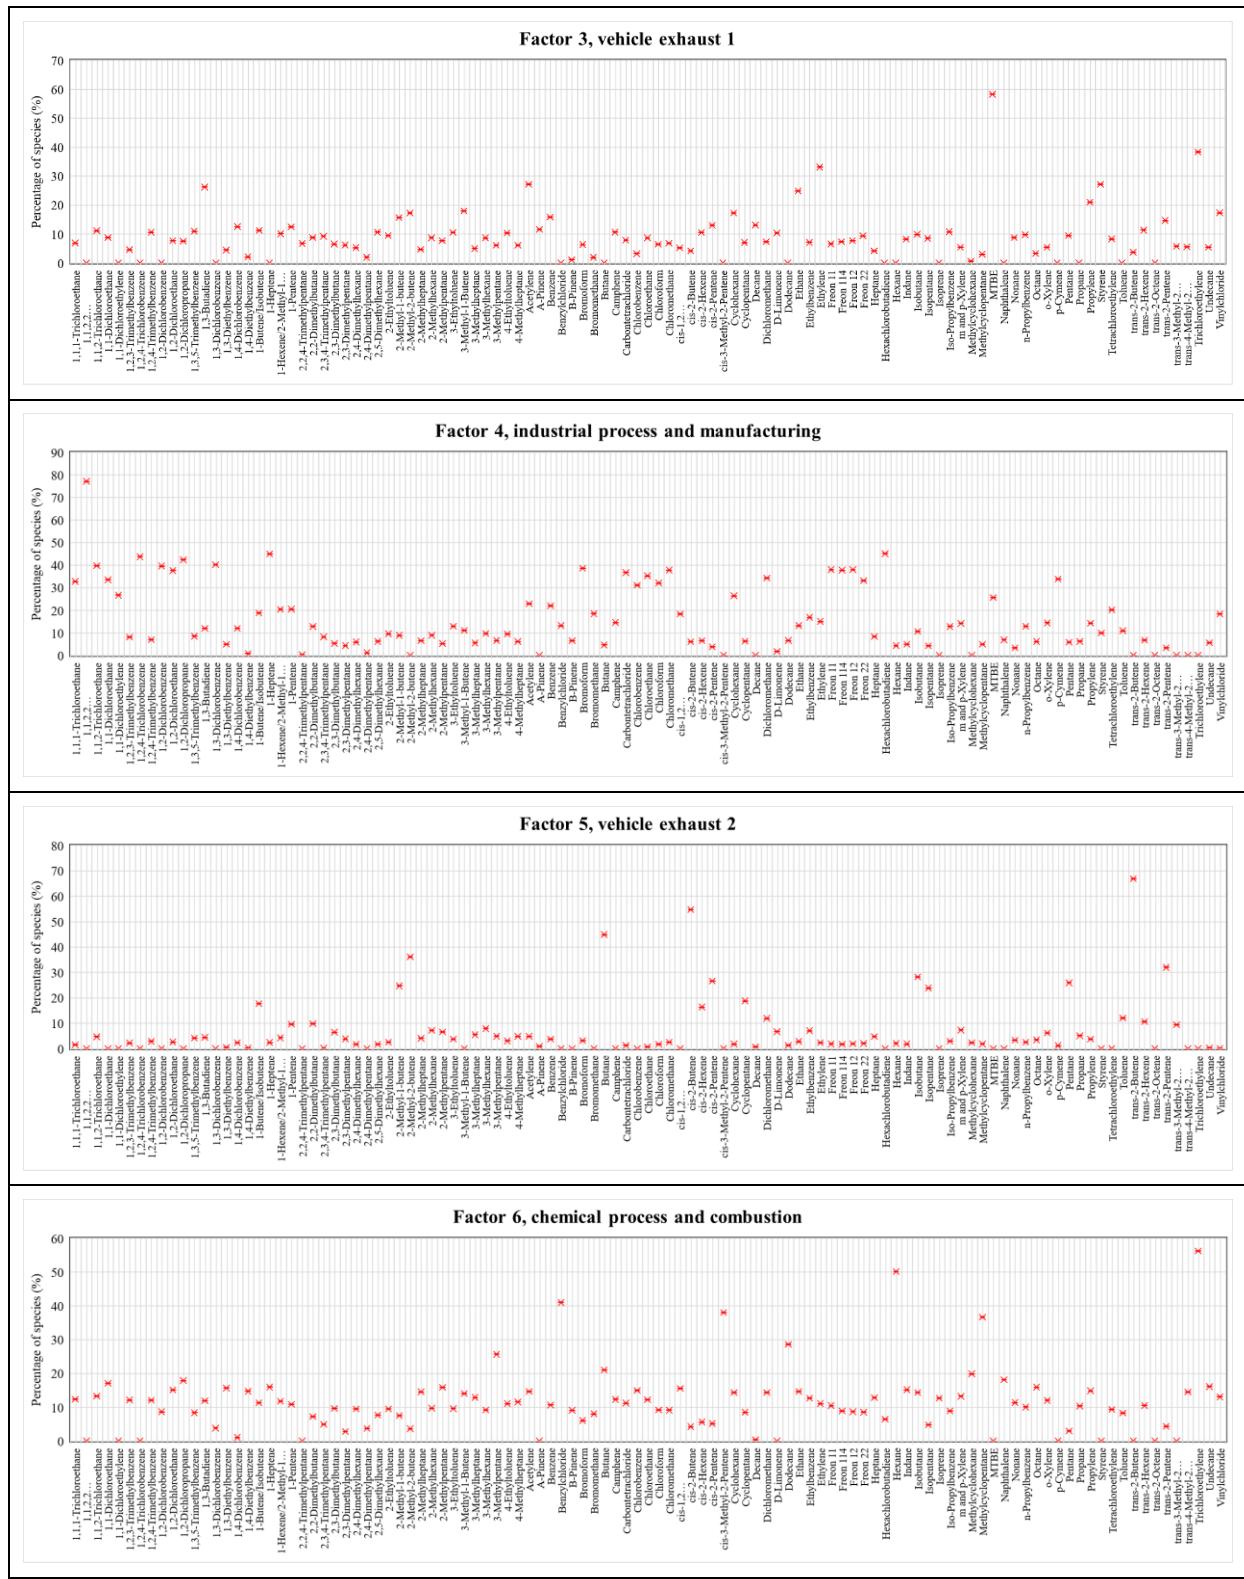

Figure S1. Windsor/Detroit border domain for emission characterization. Alkene emission rate in grams/sec is shown for illustrative purposes. In total, 25% of land cover area is Canadian and 75% US.

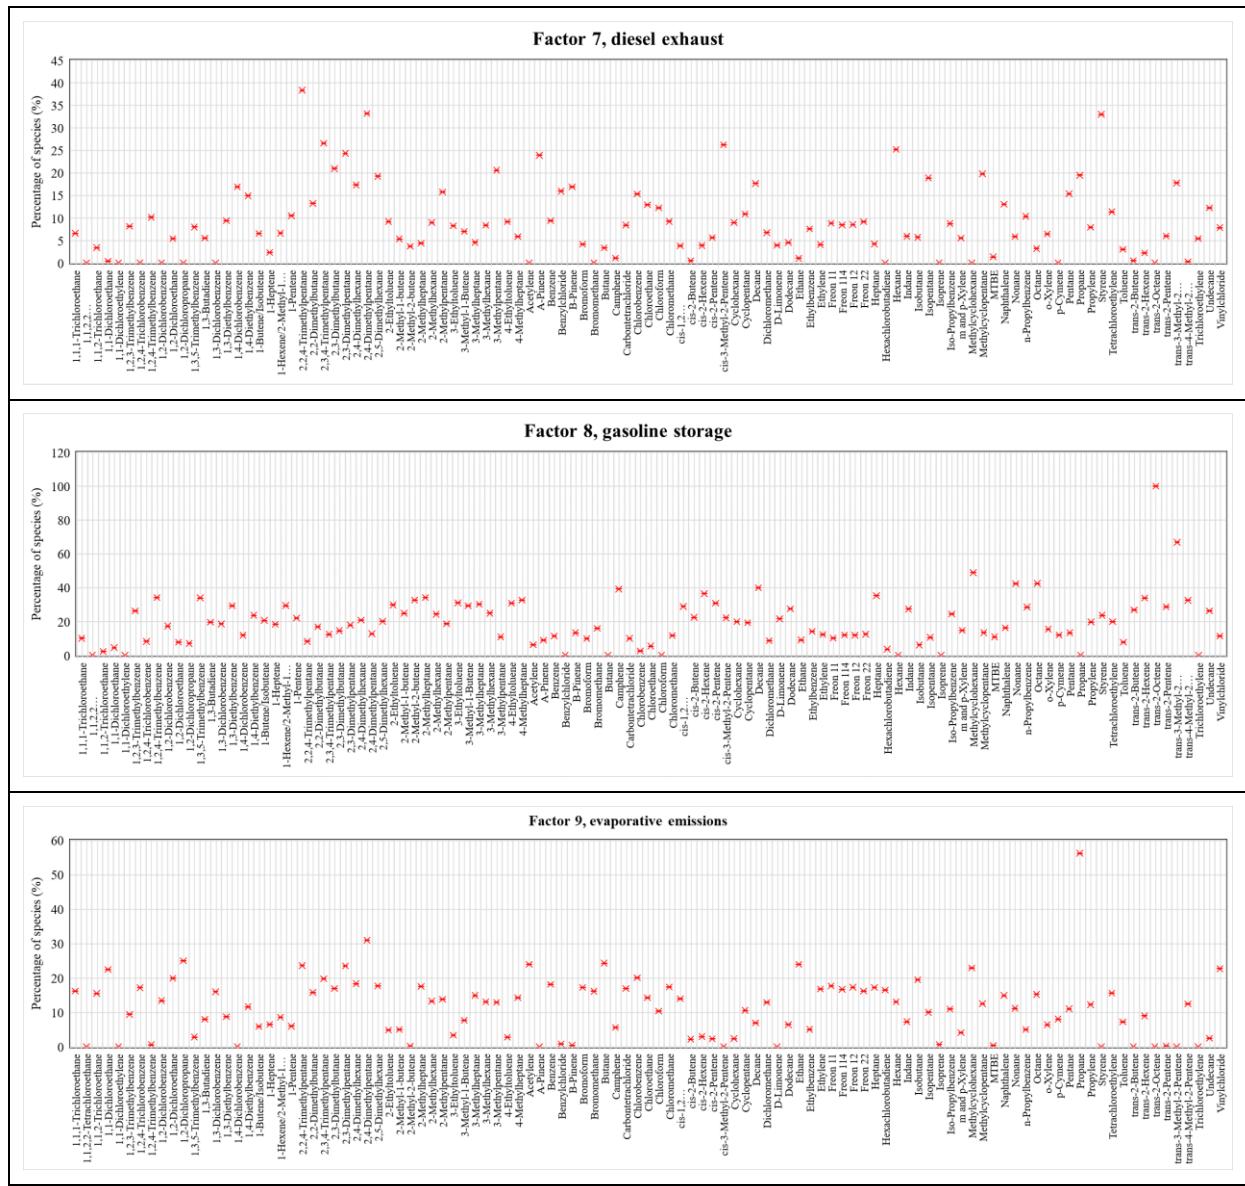

Figure S2. Chemical profiles of nine factors identified from the PMF model for ambient VOCs in Windsor. Value is the percentage of species mass concentrations assigned to that factor.
