**Abstract:** The fluctuation of the stock market has a symmetrical characteristic. To improve the performance of self-forecasting, it is crucial to summarize and accurately express internal fluctuation rules from the historical time series dataset. However, due to the influence of external interference factors, these internal rules are difficult to express by traditional mathematical models. In this paper, a novel forecasting model is proposed based on probabilistic linguistic logical relationships generated from historical time series dataset. The proposed model introduces linguistic variables with positive and negative symmetrical judgements to represent the direction of stock market fluctuation. Meanwhile, daily fluctuation trends of a stock market are represented by a probabilistic linguistic term set, which consist of daily status and its recent historical statuses. First, historical time series of a stock market is transformed into a fluctuation time series (FTS) by the first-order difference transformation. Then, a fuzzy linguistic variable is employed to represent each value in the fluctuation time series, according to predefined intervals. Next, left hand sides of fuzzy logical relationships between currents and their corresponding histories can be expressed by probabilistic linguistic term sets and similar ones can be grouped to generate probabilistic linguistic logical relationships. Lastly, based on the probabilistic linguistic term set expression of the current status and the corresponding historical statuses, distance measurement is employed to find the most proper probabilistic linguistic logical relationship for future forecasting. For the convenience of comparing the prediction performance of the model from the perspective of accuracy, this paper takes the closing price dataset of Taiwan Stock Exchange Capitalization Weighted Stock Index (TAIEX) as an example. Compared with the prediction results of previous studies, the proposed model has the advantages of stable prediction performance, simple model design, and an easy to understand platform. In order to test the performance of the model for other datasets, we use the prediction of the Shanghai Stock Exchange Composite Index (SHSECI) to prove its universality.

## 1. Introduction

Accurate predictions of future fluctuation for financial data can help investors hedge against risk. However, affected by high noise, instability, and long-term unpredictability of the stock market, it is difficult to predict the future trend of the stock market with absolute accuracy. Since each data set has its own inherent regulation of fluctuation, many researchers put forward many models that can predict the future by learning historical fluctuation laws, such as a regression analysis model [1], an autoregressive integrated moving average (ARIMA) model [2], an autoregressive conditional

heteroscedasticity (ARCH) model [3], generalized ARCH (GARCH) [4], and more. These models use different methods to extract rules from historical data and employ them to predict the future. However, due to the interference of noise and random factors, over-fitting with historical data may lead to the lack of universality of rules, which makes the predicted results unsatisfactory.

Stock market fluctuation has symmetrical characteristics, which shows two aspects including the symmetry of fluctuation directions, the symmetry of historical fluctuation, and future trend. Affected by the dynamic external environment, the fluctuation of the financial time series dataset is a complicated nonlinear system with uncertainty, which makes it difficult to be expressed by traditional mathematical models. Inspired by Zadeh's theory, Song and Chissom proposed fuzzy time series (FTS) prediction model [5–7] in 1993 to predict nonlinear complexed problems. The first fuzzy time series model was a first-order time-invariant FTS model for predicting enrollments of the university in the United States. Compared with traditional regressive models, the FTS model has many advantages because of its outstanding performance in expressing logical rules. Related models are also introduced to forecast project cost [8] and electricity load demand [9]. In a financial environment, the FTS method is widely used to predict stock index [10–12]. FTS-based models reduce the negative impact of random and uncertain factors on the prediction results by means of fuzziness, and the prediction accuracy is significantly improved when compared with the traditional regression method.

Fuzzy time series mainly consists of three parts: (1) interval division and fuzzification, (2) establishment of a fuzzy relationship, and (3) prediction and defuzzification. To state appropriate fuzzy logical relationships, fuzzy auto regressive (AR) models and fuzzy auto regressive and moving average (ARMA) models are widely adopted to show the impact of recurrence and weights in different fuzzy logical relationships [13–19]. With the development of computers, machine learning, and artificial intelligence, many scholars have even introduced neural networks and machine learning programs [19–25] to discover prediction rules from historical time series. In the forecasting process, the obtained logical relationships were used as rules. However, the FTS prediction model is based on the extraction rules of the first or multi-order continuous historical state, and the low-order model cannot fully reflect the periodic characteristics of the stock market fluctuation. At the same time, the high-order model will cause the lack of rules in the prediction stage due to the strict matching requirements of the fluctuation series.

In order to express the rules in time series more accurately and avoid the lack of rules, Guan et al. [26] introduced neutrosophic sets (NSs). NSs was proposed by Smarandache [27] from the philosophical thinking, which consisted of three degrees of truth, indeterminacy, and falsity. Many scholars have extended the application of the neutrosophic set to the field of disease diagnosis, prediction, and so on. In Guan's model, historical states are mapped to the three dimensions of the neutrosophic set, and the matching of rules is realized by similarity, which avoids the problem of rules missing in the multi-order model. However, Guan's model cannot reflect more detailed information such as fluctuation range because it maps the fluctuation states into only three dimensions.

Inspired by this, we introduce probabilistic linguistic terms set to express the fluctuation status and distance measurement to find the best matching rule. The probabilistic linguistic terms set was proposed by Pang et al. [28] in 2016. Each term was composed of corresponding probabilistic information, and Tang et al. [29] called it a probabilistic linguistic element. Linguistic variables in a probabilistic linguistic term set have positive and negative symmetrical judgements, which are employed to express different levels of decision direction. The probabilistic linguistic term set enriches decision makers' way of expressing preference information and strengthens their ability of expressing uncertainty information. Probabilistic linguistic has been widely used in decision making [30–34], risk emergency plan decision making, and more. Probabilistic linguistics were successfully applied to decision making but rarely applied to forecasting problems.

This paper introduces probability linguistics into stock market prediction. A prediction model based on probabilistic linguistic theory and fuzzy logic relationship between current and historical states is proposed. For the initial step, the original time series of the stock market is represented as a

fluctuation time series by calculating the difference between each piece of data with that of the previous day. The fluctuation time series is then fuzzified into a fuzzy-fluctuation time series. Next, probabilistic linguistic logical rules can be generated from traditional fuzzy logical relationships. Lastly, based on the probabilistic linguistic term set expression of current status and the corresponding historical statuses, distance measurement is employed to find the most proper probabilistic linguistic logical relationship for future forecasting. The advantages of this model lies in the following aspects. (1) The combination of the symmetrical characteristic of language variables and the symmetrical direction of the stock market fluctuation makes it convenient to describe the state and evolution trend of stock market fluctuation. Meanwhile, the fuzziness of language variables helps to reduce the interference of noise information. (2) Probabilistic linguistic logical rules can explore the internal rules of the actual existence of sequential data in an unsupervised fashion. (3) The probabilistic linguistic forecasting model can reasonably reduce the influence of noises from the internal rules by proper fuzzy treatment. The main contributions of this paper are as follows. (1) It introduced the probability linguistic method into the time series forecasting model, expanding the application field of this method. (2) The expression advantages of probability linguistics in uncertainty problems improve the reflection of the uncertainty of time series fluctuation. It provides a new expression form of fuzzy time series and deepens related research. (3) The distance measure function of probability language is used as the matching method of forecasting rules, which provides a new idea for future forecasting. The Taiwan Stock Exchange Capitalization Weighted Stock Index (TAIEX) data set from 1997 to 2005 and Shanghai Stock Exchange Composite Index (SHSECI) from 1998 to 2006 are taken as examples to verify the validation and universality of the proposed model. We also compare experimental results with some existing models to test the performance.

The second part introduces the basic concepts of fuzzy fluctuation time series and probability linguistic related theories. The third part introduces the prediction method based on probability linguistic logical rules. The fourth part uses the Taiwan Stock Exchange Capitalization Weighted Stock Index (TAIEX) data set from 1997 to 2005 and Shanghai Stock Exchange Composite Index (SHSECI) data from 2007 to 2015 to forecast the stock market. The fifth part summarizes the conclusions and potential problems in future research.

## 2. Preliminaries

### 2.1. Definition of Fuzzy-Fluctuation Time Series (FFTS)

Fuzzy time series was proposed by Song and Chissom [5–7]. In this section, we propose the concept of fuzzy-fluctuation time series (FFTS) based on existing Fuzzy time series.

**Definition 1 (Linguistic Fuzzy Set).** Let  $U$  be a universe of discourse, then a fuzzy set  $Y = \{y_0, y_1, \dots, y_\tau\}$  in  $U$  can be defined by its membership function,  $\mu_Y : U \rightarrow [0, 1]$ , where  $\mu_Y(u_i)$  denotes the grade of membership of  $u_i$ ,  $U = \{u_1, u_2, \dots, u_i, \dots, u_m\}$ .

Let  $S = \{s_0, s_1, \dots, s_\tau\}$  be a linguistic term set (LTS) describing the meaning of the fuzzy set with  $s_\alpha$  corresponding to  $y_\alpha$  ( $\alpha = 1, 2, \dots, \alpha, \dots, \tau$ ). For example,  $S = \{s_0 : \text{low}, s_1 : \text{slightly low}, s_2 : \text{fair}, s_3 : \text{slightly high}, s_4 : \text{high}\}$  describes the fluctuation trends of a stock market. The element  $s_\alpha$  and its subscript  $\alpha$  are strictly monotonically increasing [35]. Therefore, the function can be defined by  $f : S_\alpha = f(\alpha)$ .

**Definition 2 (Fuzzy-Fluctuation Time Series).** Let  $H(t)$  ( $t = 1, 2, \dots, T$ ) be a time series of real numbers, where  $T$  is the number of the time series.  $F(t)$  can be defined by  $F(t) = H(t) - H(t-1)$  ( $t = 2, 3, \dots, T$ ), where  $F(t)$  is called fluctuation time series (FTS). Each element of  $F(t)$  can be represented by a linguistic fuzzy set  $X(t)$  ( $t = 2, 3, \dots, T$ ) as defined in Definition 1.  $X(t)$  is a fuzzy-fluctuation time series (FFTS) generated from the original  $F(t)$ .

**Definition 3 (Fuzzy-Fluctuation Logical Relationship).** Let  $X(t) (t = n + 1, n + 2, \dots, T, n \geq 1)$  be a FFTS. Assume  $X(t)$  is determined by  $X(t - 1), X(t - 2), \dots, X(t - n)$ , then the fuzzy-fluctuation logical relationship is represented by:

$$X(t - 1), X(t - 2), \dots, X(t - n) \rightarrow X(t) \quad (1)$$

It is called the  $n$ th-order fuzzy-fluctuation logical relationship (FFLR) of the fuzzy-fluctuation time series, where  $X(t - n), \dots, X(t - 2), X(t - 1)$  is called the left-hand side (LHS) and  $X(t)$  is called the right-hand side (RHS) of the FFLR.

## 2.2. Concept of Probabilistic Linguistic

In 2016, Pang et al. [28] proposed the theory of the probabilistic linguistic term set (PLTS).

**Definition 4 (Probabilistic Linguistic Term Set).** Let  $S = \{s_0, s_1, \dots, s_\tau\}$  be a linguistic term set (LTS), a PLTS can be defined as:

$$h_s(p) = \{s_\alpha(p^{(\alpha)}) | s_\alpha \in S, 1 \geq p^{(\alpha)} \geq 0, \alpha = 0, 1, 2, \dots, \tau, \sum_{\alpha=0}^{\tau} p^{(\alpha)} = 1\} \quad (2)$$

where  $s_\alpha(p^{(\alpha)})$  is called a probabilistic linguistic variable (PLV), which is the linguistic term  $s_\alpha$  associated with the probability  $p^{(\alpha)}$ .

**Definition 5 (Conversion of Fuzzy Fluctuation Logical Relationship).** Let  $X(t - n), \dots, X(t - 2), X(t - 1)$  be the LHS of a  $n$ th-order FFLR. It can be converted to a probabilistic linguistic term set (PLTS) as follows.

$$L(t) = \left\{ s_\alpha(p^{(\alpha)}) | s_\alpha \in S, p^{(\alpha)} = \frac{\sum_{i=1..n} (w_i)}{n}, \alpha = 0, 1, 2, \dots, \tau, \sum_{\alpha=0}^{\tau} p^{(\alpha)} = 1 \right\} \quad (3)$$

where  $w_i = 1$  if the subscript of  $X(t - i)$  is equal to  $\alpha$  and 0, otherwise.  $L(t)$  is called the PLTS form of the LHS (PLHS) expression of a FFLR.

**Example 1.** Let  $\tau = 4$  as defined in Definition 1. The LHS of a FFLR  $s_3, s_2, s_2, s_2, s_4 \rightarrow s_2$  can be converted to a probabilistic linguistic term set (PLTS)  $(s_0(0), s_1(0), s_2(0.6), s_3(0.2), s_4(0.2))$ . For convenience, the PLHS of the FFLR can be represented by the probability of each linguistic variable of an LTS in order. For example, the above PLTS can be simplified to be represented by  $(0, 0, 0.6, 0.2, 0.2)$ .

**Definition 6 (Probabilistic Linguistic Logical Relationship).** Let  $X(t) (t = n + 1, n + 2, \dots, T)$  be a FFTS, and  $L(t)$  is the PLHS expression of the FFTS. The RHSs of FFLRs with the same  $L(t)$  can be grouped by putting all their RHSs together as on the RHS of the FFLR, which can be converted a PLTS  $R(t)$  according to definition 5. By this way, a FFLR can be represented by a probabilistic linguistic logical relationship (PLLR) as  $L(t) \rightarrow R(t)$

**Example 2.** For a FFLR  $s_3, s_2, s_2, s_2, s_4 \rightarrow s_2$ , all FFLRs with the same PLHS  $(s_0(0), s_1(0), s_2(0.6), s_3(0.2), s_4(0.2))$  are as follows:  $s_3, s_2, s_2, s_2, s_4 \rightarrow s_2$ ,  $s_4, s_2, s_2, s_3, s_2 \rightarrow s_2$ ,  $s_2, s_4, s_2, s_2, s_3 \rightarrow s_2$ ,  $s_2, s_3, s_2, s_4, s_2 \rightarrow s_4$ ,  $s_2, s_4, s_2, s_3, s_2 \rightarrow s_2$ ,  $s_2, s_2, s_4, s_2, s_3 \rightarrow s_0$ ,  $s_2, s_2, s_4, s_3, s_2 \rightarrow s_2$ ,  $s_2, s_2, s_2, s_4, s_3 \rightarrow s_4$  and  $s_2, s_3, s_2, s_2, s_4 \rightarrow s_2$ . The RHSs of these FFLRs can be grouped to  $(s_2, s_2, s_2, s_4, s_2, s_0, s_2, s_4, s_2)$ , which can be represented by  $(s_0(0.11), s_1(0), s_2(0.67), s_3(0), s_4(0.22))$ . Thus, a PLLR can be generated as  $(s_0(0), s_1(0), s_2(0.6), s_3(0.2), s_4(0.2) \rightarrow (s_0(0.11), s_1(0), s_2(0.67), s_3(0), s_4(0.22))$ , which can be simplified to be represented by  $(0, 0, 0.6, 0.2, 0.2) \rightarrow (0.11, 0, 0.67, 0, 0.22)$ .

### 2.3. Distance Measurement

**Definition 7 (Distance Measurement) [36].** Let  $h_s(p) = \{s_\alpha(p^{(\alpha)}) | \alpha = 0, 1, 2, \dots, \tau\}$  and  $h'_s(p) = \{s'_\beta(p^{(\beta)}) | \beta = 0, 1, 2, \dots, \tau'\}$  be any two PLTSs. The generalized distance between  $h_s(p)$  and  $h'_s(p)$  can be defined as follows.

$$d(h_s(p), h'_s(p)) = \left\{ \frac{1}{2} \left( \frac{1}{\tau} \sum_{(s_\alpha(p^{(\alpha)})) \in h_s(p)} \min_{(s'_\beta(p^{(\beta)})) \in h'_s(p)} \left| f^*(s_\alpha)p^{(\alpha)} - f^*(s'_\beta)p^{(\beta)} \right|^r + \frac{1}{\tau'} \sum_{(s'_\beta(p^{(\beta)})) \in h'_s(p)} \min_{(s_\alpha(p^{(\alpha)})) \in h_s(p)} \left| f^*(s'_\beta)p^{(\beta)} - f^*(s_\alpha)p^{(\alpha)} \right|^r \right) \right\}^{\frac{1}{r}} \quad (4)$$

where  $f^*$  is the linguistic scale function, which can be defined as follows.

$$f(s_\alpha) = \frac{\alpha}{\tau} (\alpha = 0, 1, \dots, \tau) \quad (5)$$

Evidently, if  $r = 1$ , then Equation (4) is reduced to the Hamming-Hausdorff distance and it is Euclidean-Hausdorff distance when  $r = 2$ .

### 2.4. Score Function

**Definition 8 (Score of PLTS) [36].** Let  $h_s(p) = \{s_\alpha(p^{(\alpha)}) | \alpha = 0, 1, 2, \dots, \tau\}$  be a PLTS. The score function  $S(h_s(p))$  of  $h_s(p)$  is defined as follows.

$$S(h_s(p)) = \sum_{\alpha=0}^{\tau} \left( \frac{\alpha - m}{m} p^{(\alpha)} \right) \quad (6)$$

where  $m = \frac{\tau}{2}$ .

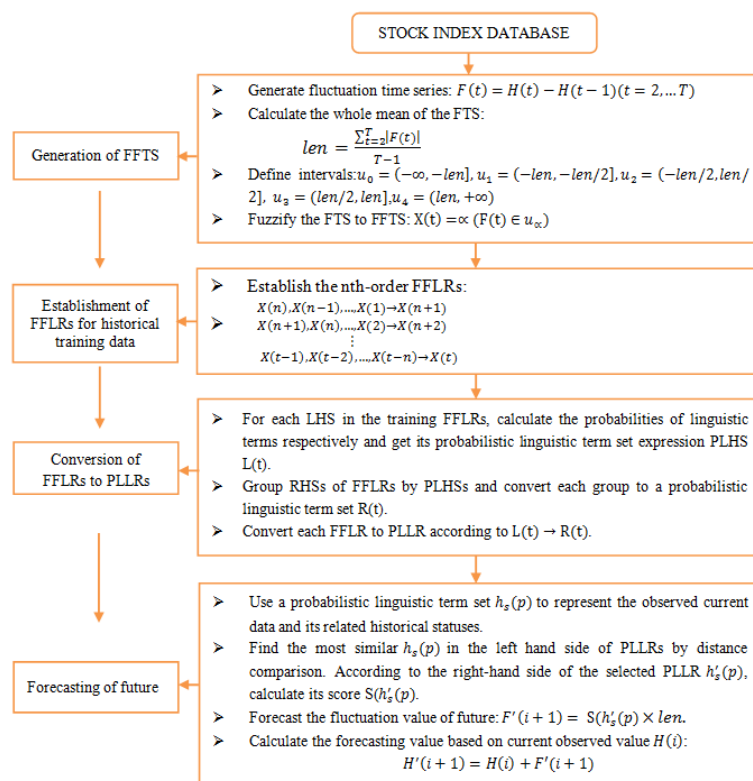

**Example 3.** For a PLTS  $(s_0(0.11), s_1(0), s_2(0.67), s_3(0), s_4(0.22))$ , its score is calculated as:

$$m = \frac{4}{2} = 2$$

$$S(s_0(0.11), s_1(0), s_2(0.67), s_3(0), s_4(0.22)) = \frac{0-2}{2} \times 0.11 + 0 + \frac{2-2}{2} \times 0.67 + 0 + \frac{4-2}{2} \times 0.22 = 0.11$$

## 3. A Novel Forecasting Model Based on Probabilistic Linguistics

Based on probabilistic linguistic logical relationships, a new forecasting model can be developed. In order to compare the forecasting results with existing works [11,22,37–44], the authentic TAXEI (Taiwan Stock Exchange Capitalization Weighted Stock Index) in 2004 is employed to illustrate the forecasting process. The dataset TAXEI in 2004 is split into two parts. The training dataset takes place from January 2004 to October 2004 and the testing dataset occurs from November 2004 to December 2004. The basic steps of the proposed model are shown in Figure 1.

**Figure 1.** Flowchart of the proposed forecasting model. FTS–fuzzy time series, FFLR–fuzzy fluctuation logical relationship, LHS–left hand side of FFLR, RHS–right hand side of FFLR, PLLR–probabilistic linguistic logical relationship, PLHS–left hand of PLLR, also the probabilistic linguistic term set (PLTS) format of a LHS.

#### Step 1. Generation of FFTS

For an original time series  $H(t) (t = 1, 2, \dots, T)$ , its corresponding fluctuation time series is determined by  $F(t) = H(t) - H(t-1) (t = 2, 3, \dots, T)$ . Let  $len$  represent the whole mean of all elements in the fluctuation time series  $F(t) (t = 2, 3, \dots, T)$ . Define intervals  $u_0 = (-\infty, -len]$ ,  $u_1 = (-len, -len/2]$ ,  $u_2 = (-len/2, len/2]$ ,  $u_3 = (len/2, len]$ ,  $u_4 = (len, +\infty)$  and linguistic terms set  $S = \{s_0 : low, s_1 : slightly low, s_2 : fair, s_3 : slightly high, s_4 : high\}$ .  $F(t) (t = 2, 3, \dots, T)$  can be fuzzified into a fuzzy-fluctuation time series  $X(t) (t = 2, 3, \dots, T)$ , according to Definition 2.

#### Step 2. Establishment of FFLRs for Historical Training Data

According to Definition 3, each  $X(t) (t = n+1, n+2, \dots, T, n \geq 1)$  in the historical training dataset can establish FFLR with its related historical data as  $X(t-1), X(t-2), \dots, X(t-n) \rightarrow X(t)$ .

#### Step 3. Conversion of FFLRs to PLLRs

According to Definition 5, each LHS of FFLRs can be expressed by a PLHS  $L(t)$ . Then, we can generate the  $R(t)$  for different  $L(t)$ , respectively, as described in Definition 6. Thus, the FFLRs for the historical training dataset are converted into PLLRs.

#### Step 4. Forecasting of the Future

For each observed point  $H(i)$  in the test time series, use a  $L(t)$  to represent its current and related historical statuses. Then, find the most similar  $h_s(p)$  in the left-hand side of PLLRs generated in step 3 by distance comparison, as described in Definition 7. According to the right-hand side of the selected PLLR  $h'_s(p)$ , calculate its score  $S(h'_s(p))$ , as described in Definition 8. The fluctuation value  $F'(i+1)$  of the next point can be forecasted as  $F'(i+1) = S(h'_s(p)) \times len$ . Lastly, the forecasting value can be calculated based on the observed point  $H(i)$  by  $H'(i+1) = H(i) + F'(i+1)$ .

## 4. Empirical Analysis

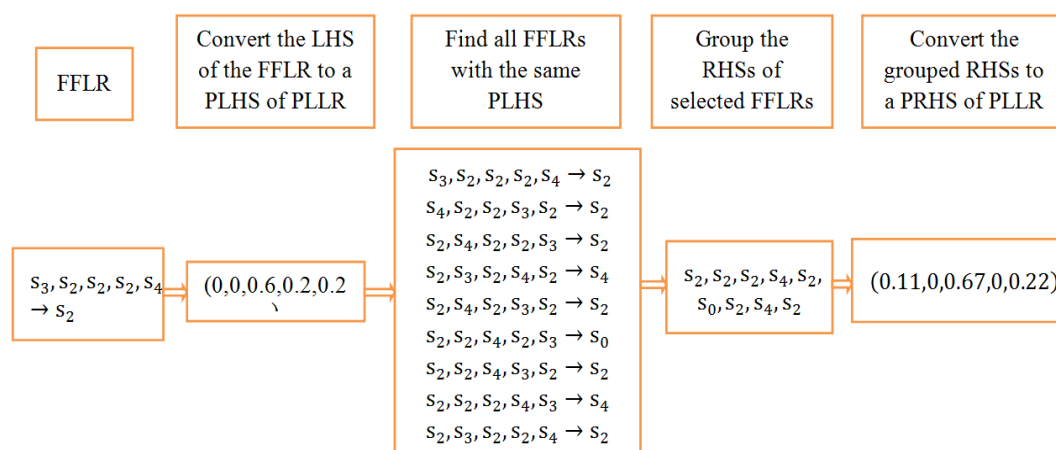

### 4.1. Forecasting of the Taiwan Stock Exchange Capitalization Weighted Stock Index

Many studies use TAIEX2004 as an example to illustrate their proposed forecasting methods [11, 18,19,22,37–44]. In order to test the accuracy, we also use TAIEX2004 to illustrate the proposed method.

Step 1: Calculate the fluctuation value for each data in the historical training dataset of TAIEX2004. Then, calculate the whole mean of the fluctuation numbers of the training dataset for further fuzzification. In this case, the whole mean of the historical dataset of TAIEX2004 from January to October is  $len = 61.87$ . Therefore, the historical training dataset can be represented by FFTS, as shown in Appendix A Table A2.

Step 2: Build  $n$ th-order FFLRs according to the relationships of each data and its historical fluctuations (as shown in Appendix A Table A2). For convenience, the element  $s_i$  is simplified to number  $i$  in the expression of FFLRs.

Step 3: In order to convert the FFLRs to PLLRs, the LHSs of the FFLRs in Table A2 are converted to PLHSs. Then, the RHSs of the FFLRs are grouped by PLHSs and expressed by probabilistic linguistic terms sets. In this way, FFLRs are converted to PLLRs. For example, the LHS of FFLR  $s_3, s_2, s_2, s_2, s_4 \rightarrow s_2$  can be represented by a probabilistic linguistic term set and simplified as  $(0, 0, 0.6, 0.2, 0.2)$ . All RHSs with the same PLHS can be grouped to  $(s_4, s_2, s_2, s_2, s_4, s_0, s_4, s_4, s_2)$ , which can be further converted to a probabilistic linguistic term set and simplified as  $(0.11, 0, 0.67, 0, 0.22)$ . Thus, a PLLR  $(0, 0, 0.6, 0.2, 0.2) \rightarrow (0.11, 0, 0.67, 0, 0.22)$  is generated. The detailed process is shown in Figure 2.

**Figure 2.** Group and converting process from the fuzzy-fluctuation logical relationship (FFLR) to the probabilistic linguistic logical relationship (PLLR). FFLR-fuzzy-fluctuation logical relationship, LHS-left hand side of FFLR, RHS-right hand side of FFLR, PLLR-probabilistic linguistic logical relationship, PLHS-left hand of PLLR, PRHS-right hand of PLLR.

In this way, the FFLRs in Table A2 can be converted into PLLRs, as shown in Table 1.

**Table 1.** Probabilistic linguistic logical relationship (PLLR) for the historical training dataset of Taiwan Stock Exchange Capitalization Weighted Stock Index (TAIEX) 2004.

PLLRs	PLLRs	PLLRs
$(0, 0, 0.6, 0.2, 0.2) \rightarrow (0.11, 0, 0.67, 0, 0.22)$	$(0.4, 0.2, 0, 0, 0.4) \rightarrow (0.25, 0.25, 0, 0.5)$	$(0.2, 0, 0.2, 0.4, 0.2) \rightarrow (0.5, 0, 0.25, 0, 0.25)$
$(0, 0, 0.8, 0.2, 0) \rightarrow (0.33, 0, 0.33, 0, 0.33)$	$(0.6, 0, 0.2, 0, 0.2) \rightarrow (0.25, 0.5, 0, 0.25, 0)$	$(0.6, 0, 0, 0, 0.4) \rightarrow (0.5, 0, 0.5, 0, 0)$
$(0, 0, 0.8, 0, 0.2) \rightarrow (0.13, 0.25, 0.25, 0, 0.38)$	$(0.6, 0.2, 0.2, 0, 0) \rightarrow (0.5, 0, 0.33, 0, 0.17)$	$(0.4, 0, 0.2, 0, 0.4) \rightarrow (0, 0, 0.33, 0.33, 0.33)$
$(0, 0, 0.6, 0, 0.4) \rightarrow (0.38, 0.13, 0.38, 0, 0.13)$	$(0.4, 0.2, 0.4, 0, 0) \rightarrow (0.33, 0, 0, 0.33, 0.33)$	$(0.2, 0, 0.2, 0.2, 0.4) \rightarrow (0, 0, 1, 0, 0)$
$(0.2, 0, 0.6, 0, 0.2) \rightarrow (0.13, 0.13, 0.38, 0.13, 0.25)$	$(0.4, 0, 0.4, 0, 0.2) \rightarrow (0.4, 0, 0.2, 0.2, 0.2)$	$(0, 0.4, 0.2, 0, 0.4) \rightarrow (1, 0, 0, 0, 0)$
$(0.2, 0, 0.4, 0, 0.4) \rightarrow (0.17, 0.17, 0.67, 0, 0)$	$(0.4, 0, 0.2, 0.2, 0.2) \rightarrow (0.4, 0.2, 0, 0.2, 0.2)$	$(0.2, 0.4, 0.2, 0, 0.2) \rightarrow (0, 0, 0, 1, 0)$
$(0.2, 0.2, 0.2, 0, 0.4) \rightarrow (0.17, 0, 0.67, 0, 0.17)$	$(0.4, 0.2, 0.2, 0.2, 0) \rightarrow (0, 0, 0.5, 0, 0.5)$	$(0, 0, 1, 0, 0) \rightarrow (0.5, 0.5, 0, 0, 0)$
$(0.4, 0.2, 0.2, 0, 0.2) \rightarrow (0.33, 0, 0.67, 0, 0)$	$(0.2, 0.2, 0.2, 0.2, 0.2) \rightarrow (0, 0.33, 0.67, 0, 0)$	$(0, 0.2, 0.8, 0, 0) \rightarrow (0, 0.5, 0.5, 0, 0.5)$
$(0.2, 0.2, 0.4, 0, 0.2) \rightarrow (0.27, 0.09, 0.27, 0.09, 0.27)$	$(0, 0.4, 0.4, 0, 0.2) \rightarrow (0, 0, 0.33, 0, 0.67)$	$(0, 0, 0.2, 0.2, 0.6) \rightarrow (0, 0, 1, 0, 0)$

Step 4: Use the PLLRs obtained from the historical training dataset to forecast the testing dataset from 1 November 2004 to 31 December 2004. For example, set current point is the date 29 October 2004 and the forecasting date is 1 November 2004. First, the 5th-order current and related historical fuzzy-fluctuation trends are  $s_2, s_3, s_2, s_0, s_2$  (as shown in Table A1 from date 29 October to 22 October), which can be represented by a probabilistic linguistic term set  $(0.2, 0, 0.6, 0.2, 0)$ . Then, by using the distance measurement method described in Definition 8 (where the parameter  $r$  is set to 1), the most optimal PLLR is  $(0.2, 0, 0.6, 0.2, 0) \rightarrow (0.25, 0, 0.75, 0, 0)$ . Therefore, the fuzzified forecasting fluctuation can be obtained by the score of the RHS of PLLR.

$$S(0.25, 0, 0.75, 0, 0) = ((0-2)/2) \times 0.25 + ((1-2)/2) \times 0 + ((2-2)/2) \times 0.75 + ((3-2)/2) \times 0 + ((4-2)/2) \times 0 = -0.25$$

It can be defuzzified by:

$$F'(i+1) = -0.25 \times len = -0.25 \times 61.87 = -15.37$$

At last, the forecasted value can be calculated through the current value and the fluctuation value.

$$H'(i+1) = H(i) + F'(i+1) = 5705.93 - 15.37 = 5690.46$$

The other forecasting results are shown in Table 2 and Figure 3.

Figure 3. Forecasting results from 1 November 2004 to 31 December 2004.

2004/11/29	5785.3	5809.58	591.65	2004/12/30	6100.9	6091.07	95.887
2004/11/30	5844.8	5805.88	1511.4	2004/12/31	6139.7	6103.44	1314.2
2004/12/1	5798.6	5798.36	0.0681	Root Mean Square Error (RMSE) 55.04			

From the perspective of accuracy, a performance assessment can be carried out comparing forecasted values and the actual values. There are many indicators that have been verified to be useful for difference comparisons, such as the mean squared error (MSE), the root of the mean squared error (RMSE), the mean absolute error (MAE), and the mean percentage error (MPE). The definitions are described as follows.

$$MSE = \frac{\sum_{t=1}^n (forecast(t) - actual(t))^2}{n} \quad (7)$$

$$RMSE = \sqrt{\frac{\sum_{t=1}^n (forecast(t) - actual(t))^2}{n}} \quad (8)$$

$$MAE = \frac{\sum_{t=1}^n |(forecast(t) - actual(t))|}{n} \quad (9)$$

$$MPE = \frac{\sum_{t=1}^n |(forecast(t) - actual(t))|/actual(t)}{n} \quad (10)$$

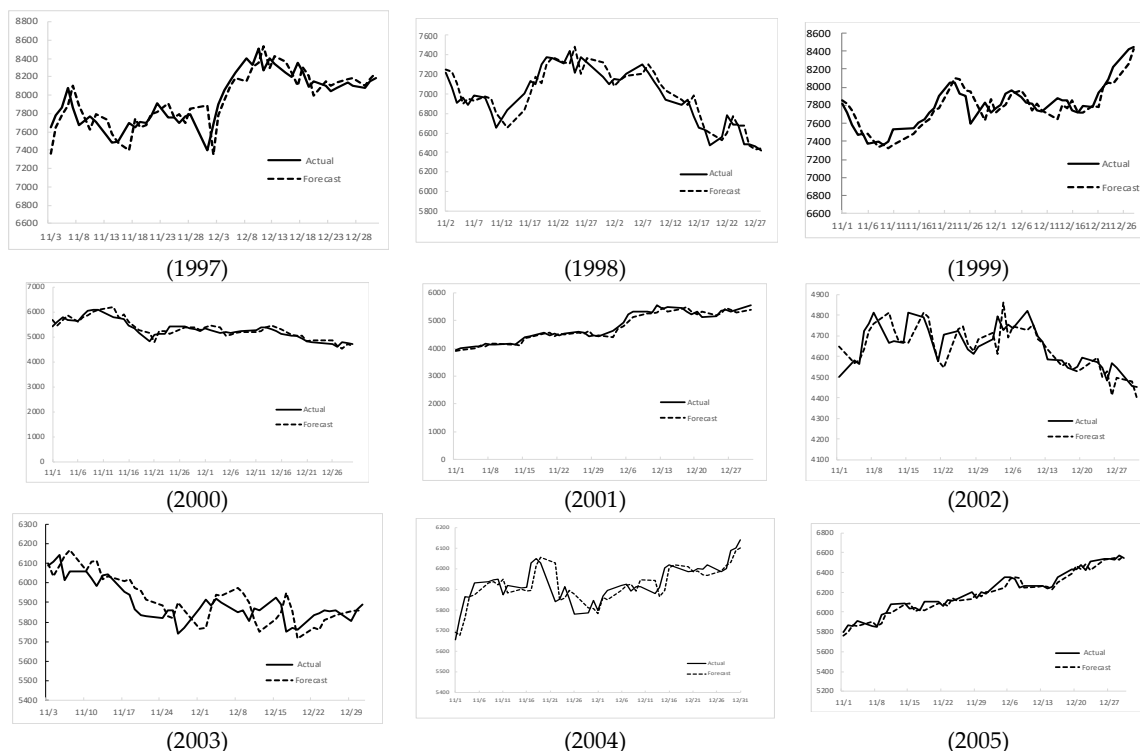

where  $t = 1, 2, \dots, n$  denotes the position of series to be compared,  $n$  denotes the number of the series, and forecast ( $t$ ) and actual ( $t$ ) denote the forecasted value and actual value at position  $t$ , respectively.

With respect to the proposed method for the 5th-order forecasting model, the mean squared error (MSE), the root of the mean squared error (RMSE), the mean absolute error (MAE), and the mean percentage error (MPE) are 3029.91, 55.04, 5927.36, 38.87, respectively. The forecasting errors of RMSE for different  $n$ th-order models are shown in Table 3.

**Table 3.** Comparison of forecasting errors for different nth-order models.

	n									Average
	2	3	4	5	6	7	8	9	10	
RMSE	56.82	55.43	57.96	55.04	59.89	59.48	68.80	62.61	57.33	59.26

Figure 4 and Table 4 describe the forecasting results and the RMSEs for TAIEX from 1997 to 2005.

Note: the best forecasting results are marked in bold.

From Table 5, we can see that the performance of the method presented in this paper is stable and acceptable. Although performance of the proposed method is not the best method for all time

series, its average performance is the best. In fact, accuracy is not the unique judgement criteria for a forecasting method. One particularly preferred aspect is that it can be easily realized by a computer because it does not need human intervention. Meanwhile, the introduction of a probabilistic linguistic term set makes it easy to understand and possible to employ a distance measurement method to find out the most appropriate rules for further forecasting. From that point of view, it has better universality for different types of time series.

#### 4.2. Forecasting Shanghai Stock Exchange Composite Index

In order to verify the universality of the proposed model, the famous SHSECI (Shanghai Stock Exchange Composite Index) in China is also taken as an example. We carry out forecasting for the SHSECI from 2007 to 2015 by the proposed method. The realistic datasets for each year are also divided into the training dataset and testing dataset. The RMSEs of the forecasting results for SHSECI from 2007 to 2015 are shown in Table 6. It shows that the SHSECI stock market can be successfully forecasted by the proposed model.

**Table 6.** RMSEs of forecasting results for the Shanghai Stock Exchange Composite Index (SHSECI) from 2007 to 2015.

Years	2007	2008	2009	2010	2011	2012	2013	2014	2015
RMSE	117.63	64.82	53.18	47.58	30.45	27.83	22.42	53.65	65.57

## 5. Conclusions

Considering the symmetrical characteristics of stock market fluctuation, this paper proposes a novel forecasting model based on symmetrical linguistic variables. The proposed model extends traditional FFLRs to PLLRs. Through such a transformation, distance measurement between probabilistic linguistic term sets can be employed to optimize the expression of forecasting rules. The greatest aspect of the proposed method is that it can retain more detailed fluctuation information while reducing overfitting information. Meanwhile, the distance comparison function makes it easy to solve new situations and avoid a lack of rules. This makes it more universal when compared with traditional models. In addition, the definability of high order and linguistic terms makes it more flexible than many other methods. Compared with the prediction results of previous studies, the proposed model has the advantages of stable prediction performance, simple model design, and an easy to understand platform. The success of forecasting SHSECI verifies the universality of the proposed model.

This model uses the simplest form of probability linguistic variables to express the fuzzy fluctuation states of a time series. In a realistic stock market, there are a lot of disturbance factors concealing the internal fluctuation law of the time series. In order to reveal the internal fluctuation law, it is important to select a suitable method to retain the information reflecting the internal fluctuation law and to erase the influence of noise to a maximum extent. From this perspective, the selection of the fuzzification method needs to be deeply discussed. In this regard, the existing decision-making methods can provide useful information [45]. In the follow-up study, we can make full use of the latest research results in decision-making and further optimize the prediction method. At the same time, other external factors related to the fluctuation of the stock market will also be introduced to establish new models.
