**Abstract:** First-principles calculations were used to estimate the anisotropic elastic and thermal properties of  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ )  $M_2AX$  phases. The crystals' elastic properties were computed using the Voigt-Reuss-Hill approximation. Firstly, the material's elastic anisotropy was explored, and its mechanical stability was assessed. According to the findings,  $Ti_2InC$ ,  $Ti_2InN$ ,  $Zr_2InC$ , and  $Zr_2InN$  are all brittle materials. Secondly, the elasticity of  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ )  $M_2AX$  phase are anisotropic, and the elasticity of  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ ) systems are different; the order of anisotropy is  $Ti_2InN > Ti_2InC$ ,  $Zr_2InN > Zr_2InC$ . Finally, the elastic constants and moduli were used to determine the Debye temperature and sound velocity.  $Ti_2InC$  has the maximum Debye temperature and sound velocity, and  $Zr_2InN$  had the lowest Debye temperature and sound velocity. At the same time,  $Ti_2InC$  had the highest thermal conductivity.

## 1. Introduction

The ternary layered compound MAX phase has the common characteristics of ceramics and metals, and has become a research hotspot in the field of structural ceramics for more than 20 years. High damage tolerance and high fracture toughness are essential characteristics that distinguish it from traditional ceramics [1–6]. This type of material has a similar nano-layered crystal structure (space group  $P6_3/mmc$ ), which is named the " $M_{n+1}AX_n$ " phase, referred to as MAX phase, where M is a transition metal element, A is a IIIA or IVA group element, and X is C or N, ( $n = 1\sim 3$ ) [7–9]. MAX phase compounds can be regarded as the formation of a layer of main group atoms inserted into the binary carbon/nitride lattice. Characterization shows the extraordinary properties of MAX phase materials. They have many excellent properties, such as high damage tolerance, high fracture toughness, low hardness, machinability, thermal shock resistance, high damping, high stiffness, and good electrical and thermal conductivity [10,11], etc. Among them, 211-type MAX phase compounds also have similar properties. This extraordinary performance quickly attracted widespread attention in the field of ceramics.

At present, Z. J. Yang et al. have carried out many theoretical studies on the novel hysteresis behavior of  $Zr_2InC$  based on plane-wave pseudopotential (PW-PP) density functional theory (DFT) calculations, and the mechanical and electronic properties of  $Zr_2InC$  under pressure were investigated using first principles [12]. A.D. Bortolozzo et al. investigated the  $Ti_2InN$  phase by X-ray diffraction and magnetic and resistivity measurements, and the results clearly showed that  $Ti_2InN$  is the first nitride superconductor belonging to the  $M_{n+1}AX_n$  family [13]. Sun et al. investigated the relationship between chemical bonds and the elastic properties of  $M_2AN$  ( $M = Ti, Zr, Hf, V, Nb, Ta, Cr, Mo$  and  $W$ ,  $A = Al, Ga$  and  $Ge$ ) by calculation [14]. The study showed that with the increase of valence electron concentration, the bulk modulus of  $M_2AN$  increases by a factor of 1.8, and the coupling between the MN layer and the A layer weakens. Despite these studies, theoretical studies

of the  $M_2InX$  phase are not sufficient. Previously, MAX carbides have received the greatest attention, while MAX nitrides have received less. In general, the nitride phase and the carbide phase are very similar. Therefore, first-principles calculations are employed to investigate the structure, elastic anisotropy, and thermodynamic properties of  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ )  $M_2AX$  phase ceramics, providing a comprehensive complement to previously unexplored areas.

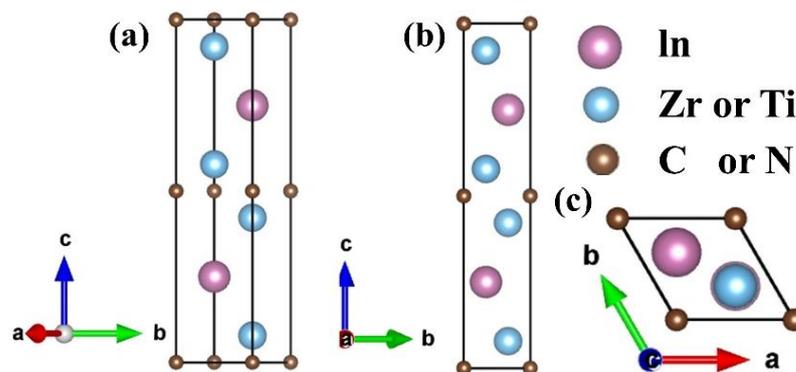

## 2. Methods

In this work,  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases were analyzed using the Cambridge Sequential Total Energy Package (CASTEP) [15,16] of Density Functional Theory (DFT) [17]. The interactions between electrons and ionic nuclei were calculated using on-the-fly generation (OTFG), ultrasoft pseudopotentials (USPPs), and the Perdew–Wang generalized-gradient approximation (PW91) [18–21] method in generalized gradient approximation (GGA) was utilized to model exchange correlation potential. In this work, the geometric optimization tolerance was set to  $5 \times 10^{-6}$  eV/atom of total energy difference, the maximum ionic Hellmann–Feynman force was 0.01 eV/atom, the maximum ion displacement was  $5 \times 10^{-4}$ , and the maximum stress was 0.02 GPa; the  $M_2InX$  phases plane-wave cutoff energy was set to 450 eV and the k-point in the first irreducible Brillouin zone was selected as  $10 \times 10 \times 2$ . In this calculation, we conducted relevant tests on  $1 \times 1 \times 1$ ,  $1 \times 1 \times 2$ ,  $1 \times 2 \times 2$ , and  $2 \times 2 \times 2$  supercells, and found that when using  $1 \times 1 \times 2$ ,  $1 \times 2 \times 2$ ,  $2 \times 2 \times 2$  supercells, the resulting energy change was about 1 meV/atom. The total number of atoms in  $1 \times 1 \times 1$ ,  $1 \times 1 \times 2$ ,  $1 \times 2 \times 2$ , and  $2 \times 2 \times 2$  supercells were 8, 16, 32, and 64, respectively. Considering the computational cost and time, this study finally decided to use a  $1 \times 1 \times 2$  supercell for the calculation.

## 3. Results and Discussion

### 3.1. Single-Crystal Structural Properties

Firstly, the most stable hexagonal  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phase crystal structure was determined, as shown in Figure 1. Fully relaxing atomic locations and lattice parameters yielded a crystal structure in equilibrium. Table 1 displays the computed lattice parameters  $a$  and  $c$ , as well as their volumes and formation enthalpies. The calculated structural parameters of the  $M_2InX$  phase are in agreement with other experimental results [12,22]. This demonstrates the dependability and precision of the simulations presented in this study, and provided us with the confidence to continue investigating the characteristics of  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ ) ceramics.  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ ) crystallize in the  $P6_3/mmc$ -space group with the Wyckoff positions of  $4f$  ( $1/3, 2/3, Z_{Zr/Ti}$ ) for Zr/Ti atoms,  $2d$  ( $1/3, 2/3, 3/4$ ) for In atoms, and  $2a$  ( $0, 0, 0$ ) for N/C atoms, and the unit cell was made up of 8 atoms, including  $2X$ ,  $4M$ , and  $2In$  atoms. The atoms were aligned along the  $c$ -axis in the order  $X-In-M-X$ , as shown in Figure 1.

The computed lattice parameters  $a$  and  $c$ , their volumes, the formation enthalpy, and cohesive energy are listed in Table 1. As we all know, thermodynamic stability can be understood to some extent as the concept of minimal energy, which states the lower the energy, the greater the system's thermodynamic stability. As a result, thermodynamic stability is described using quantities such as formation enthalpy  $\Delta H_f$ , and cohesive energy  $E_c$ . When the formation enthalpy and cohesive energy are both negative, the structure is stable. Therefore, the greater the negative value, the greater the substance's stability. The calculation is as follows:

$$E_c(M_2\text{InX}) = \frac{1}{8}[E(M_2\text{InX}) - 4E_{iso}(M) - 2E_{iso}(\text{In}) - 2E_{iso}(X)] \quad (1)$$

$$\Delta H_f(M_2\text{InX}) = \frac{1}{8}[E(M_2\text{InX}) - 4E_{bulk}(M) - 2E_{bulk}(\text{In}) - 2E_{bulk}(X)] \quad (2)$$

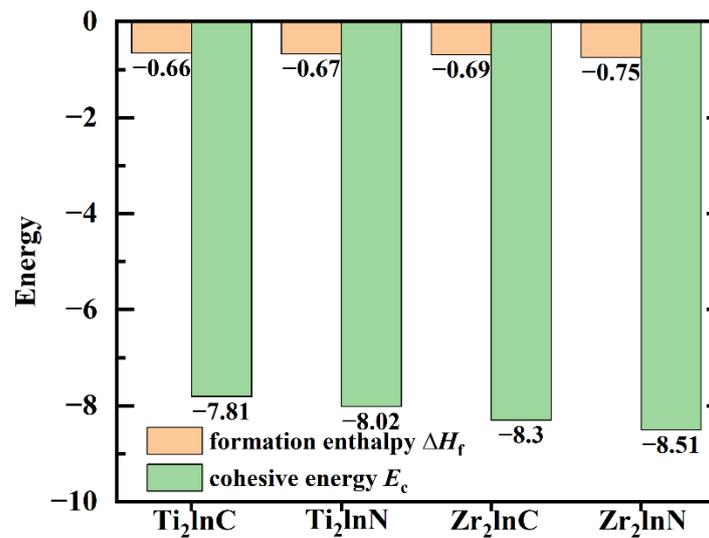

Here,  $E$  is the total energy of  $M_2\text{InX}$ .  $E_{bulk}(M)$ ,  $E_{bulk}(\text{In})$  and  $E_{bulk}(X)$  represent the energies of single  $M$ ,  $\text{In}$ , and  $X$  atoms in a stable state, respectively.  $E_{iso}(M)$ ,  $E_{iso}(\text{In})$ , and  $E_{iso}(X)$  are the energies of isolated  $M$ ,  $\text{In}$ , and  $X$  atoms, respectively.

Table 1 and Figure 2 show the computed cohesive energy  $E_c$  and formation enthalpy  $\Delta H_f$  of Ti<sub>2</sub>InC, Ti<sub>2</sub>InN, Zr<sub>2</sub>InC, and Zr<sub>2</sub>InN, as well as other experimental data for related compounds [12,13,22–24]. The predicted  $E_c$  and  $\Delta H_f$  values for the compounds in Table 1 are negative, indicating that Ti<sub>2</sub>InC, Ti<sub>2</sub>InN, Zr<sub>2</sub>InC, and Zr<sub>2</sub>InN are thermodynamically stable and have stronger bond strengths. Furthermore, the sequence of  $E_c$  and  $\Delta H_f$  values is Ti<sub>2</sub>InC > Ti<sub>2</sub>InN and Zr<sub>2</sub>InC > Zr<sub>2</sub>InN. Therefore, the order of thermodynamic stability is Ti<sub>2</sub>InN > Ti<sub>2</sub>InC and Zr<sub>2</sub>InN > Zr<sub>2</sub>InC. The comprehensive comparison shows that Zr<sub>2</sub>InN and Ti<sub>2</sub>InN have the highest thermodynamic stability. If Zr<sub>2</sub>InN and Ti<sub>2</sub>InN continue to be compared, it can be seen that Zr<sub>2</sub>InN has the highest thermodynamic stability, which is shown in Figure 2.

### 3.2. Elastic Properties

This work is based on the stress-strain approach of Hooke's law to analyze mechanical stability, and the elastic constants were determined by applying normal stress, shear stress, and six different deformations. Table 2 shows the calculated elastic constants  $C_{ij}$  and elastic compliance constants  $S_{ij}$  of Ti<sub>2</sub>InC, Ti<sub>2</sub>InN, Zr<sub>2</sub>InC, and Zr<sub>2</sub>InN. Only five elastic constants ( $C_{11}$ ,  $C_{12}$ ,  $C_{13}$ ,  $C_{33}$ ,  $C_{44}$ ) are independent for hexagonal crystals [25]. The mechanical stability criteria for hexagonal crystals are given by the following equation [26–28]:

$$C_{11} - C_{12} > 0; C_{44} > 0; C_{11} + C_{12} - 2C_{13}^2/C_{33} > 0 \quad (3)$$

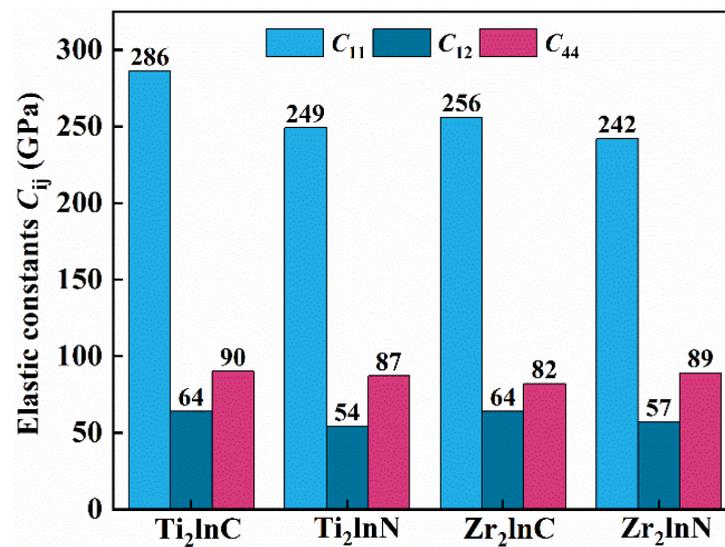

**Figure 2.** The cohesive energy  $E_c$  (in eV/atom) and formation enthalpy  $\Delta H_f$  (in eV/atom) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

**Table 2.** The elastic constants  $C_{ij}$  (in GPa) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

$Zr_2InN$	242	225	89	83	57	88	This work
	237	199	76		55	82	Theo. [23]

Combining the elastic constants calculated in Table 2 and Figure 3, it is not difficult to see that these constants satisfy all the above conditions, proving that  $Ti_2InC$ ,  $Ti_2InN$ ,  $Zr_2InC$ , and  $Zr_2InN$  are mechanically stable. Usually, the elastic constant represents some important physical meaning, for example,  $C_{11}$  and  $C_{33}$  correspond to the linear compression resistance of the  $a$  and  $c$  axes, respectively. Table 2 reflects that the  $C_{33}$  value of  $M_2InX$  is significantly smaller than the  $C_{11}$  value, indicating that  $M_2InX$  has a high compressibility along the  $c$ -axis. To begin with, for the  $Ti_2InX$  ( $X = C, N$ ) system,  $Ti_2InC$  has the highest  $C_{11}$  value (286 GPa) and  $C_{33}$  value (244 GPa), while  $Ti_2InN$  has the lowest  $C_{11}$  value (229 GPa) and  $C_{33}$  value (228 GPa), suggesting that  $Ti_2InC$  is the least compressible along the  $a$ -axes and  $c$ -axes, while  $Ti_2InN$  is the most compressible along the  $a$ -axes and  $c$ -axes. This is consistent with  $Ti_2InC$  having the strongest chemical bond and  $Ti_2InN$  having the weakest chemical bond [13,22]. It can also be seen that for the system of  $Zr_2InX$  ( $X = C, N$ ),  $Zr_2InC$  is the most incompressible along the  $a$ - and  $c$ -axes, while  $Zr_2InN$  is the most compressible along the  $a$ - and  $c$ -axes. From the comparison of the above two systems, it can be understood that  $Ti_2InC$  and  $Zr_2InC$  are the most incompressible of the two systems, respectively. If the values of  $C_{11}$  and  $C_{33}$  are continuously compared in the  $M_2InC$  ( $M = Ti, Zr$ ) system, it can be seen that  $Ti_2InC > Zr_2InC$ , and therefore the compressibility of  $Ti_2InC$  along the  $a$ -axis and  $c$ -axis is the smallest, which also confirms that  $Ti_2InC$  has a great elasticity constant.

It is well-known that  $C_{12}$ ,  $C_{44}$ , and  $C_{66}$  are related to shear modulus, and larger values of  $C_{12}$ ,  $C_{44}$ , and  $C_{66}$  correspond to larger shear modulus. For  $Ti_2InX$  ( $X = C, N$ ) the order of  $C_{12}$ ,  $C_{44}$ , and  $C_{66}$  is  $Ti_2InC > Ti_2InN$ , while for  $Zr_2InX$  ( $X = C, N$ ) the order of  $C_{12}$ ,  $C_{44}$ , and  $C_{66}$  is  $Zr_2InC > Zr_2InN$ . Therefore,  $Ti_2InC$  and  $Zr_2InC$  should have the highest shear moduli. Similarly, by comparing the values of  $C_{12}$ ,  $C_{44}$ , and  $C_{66}$  in the  $M_2InC$  ( $M = Ti, Zr$ ) system, it can be seen that  $Ti_2InC > Zr_2InC$ , which proves that  $Ti_2InC$  has the highest shear modulus.

**Figure 3.** The elastic constants  $C_{ij}$  (in GPa) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

### 3.3. Elastic Moduli

In general, using elastic modulus as a parameter to measure the mechanical properties of polycrystals is more convincing than using the elastic constant. In practice, because most materials are polycrystalline, the applied elastic modulus can more accurately describe the anisotropy of the material than the elastic constant. The Reuss-Hill-Voigt approximation is generally used to obtain the elastic modulus for  $M_2InX$  phase, which contains Young's modulus  $E$ , bulk modulus  $B$ , and shear modulus  $G$  [24,29,30]. The following are the specific expressions of  $B_H$ ,  $E_H$ , and  $G_H$ :

$$G_H = \frac{(G_V + G_R)}{2} \quad (4)$$

$$B_H = \frac{(B_R + B_V)}{2} \quad (5)$$

$$E = \frac{9G_H B_H}{(3B_H + G_H)} \quad (6)$$

Bulk modulus can be specifically divided into lower bulk modulus ( $B_V$ ) and upper bulk modulus ( $B_R$ ). Likewise, the shear modulus has a lower shear modulus ( $G_V$ ) and an upper shear modulus ( $G_R$ ).

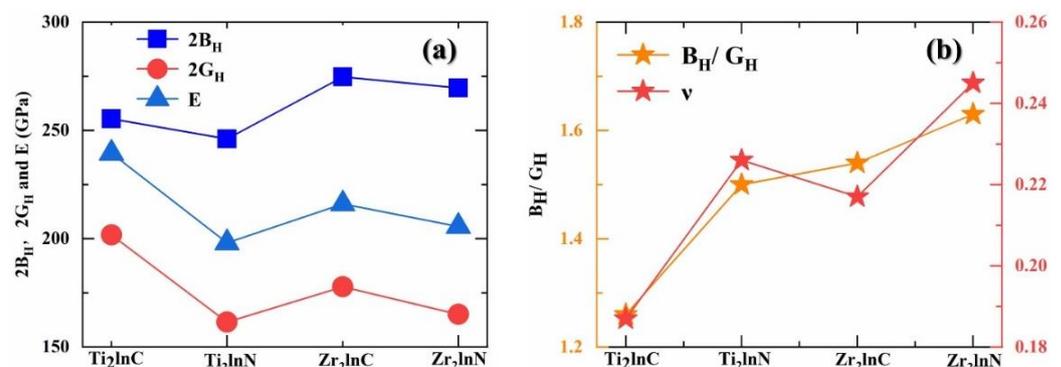

Table 3 shows the estimated and reference data for the elastic modulus  $M_2InX$  compound [12,13,23,31]. The results of this computation are obviously close to the findings stated in the reference. Bulk moduli are frequently used to define a material's compressibility under hydrostatic pressure. A higher bulk modulus indicates less compressibility. To put it another way, the higher the bulk modulus, the stiffer the material. It can be seen from Table 3 that for  $Ti_2InX$  ( $X = C, N$ ), the  $B_H$  value of  $Ti_2InC$  is greater than that of  $Ti_2InN$ , indicating that  $Ti_2InC$  has higher incompressibility. For  $Zr_2InX$  ( $X = C, N$ ),  $Zr_2InC$  has higher incompressibility. It is well-known that the larger bulk modulus in compounds originates from the strong hybridization between orbitals. Therefore,  $Ti_2InC$  and  $Zr_2InC$  should have the strongest orbital hybridization.

Furthermore, the stiffness of a material can be defined by its Young's modulus; the greater the Young's modulus, the greater the stiffness of the material. Table 3 shows that  $Ti_2InC$  and  $Zr_2InC$  have the maximum stiffness in the  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ ) systems, respectively.  $Ti_2InC$  has the highest stiffness in the  $M_2InC$  ( $M = Ti, Zr$ ) system, because its Young's modulus is greater than that of  $Zr_2InC$ . Additionally, the shear modulus can be used to forecast the hardness of a material. In general, the shear modulus characterizes the degree to which the shape of the material is affected by the shear force

acting on it. The larger the shear modulus, the greater the corresponding deformation resistance. Therefore, the greater the shear modulus, the higher the hardness and strength of the material. From the conclusion drawn from the elastic constants in the previous section, it can be seen that  $Ti_2InC$  and  $Zr_2InC$  have the highest shear moduli, so the hardness of both  $Ti_2InC$  and  $Zr_2InC$  is highest. Further comparison of the  $M_2InC$  ( $M = Ti, Zr$ ) system shows that  $Ti_2InC$  has the largest shear modulus, so the deformation resistance of  $Ti_2InC$  is the largest. Finally, Figure 4a shows the comparison between  $B$ ,  $G$ , and  $E$ . Generally, the plastic properties of materials can be characterized by  $B/G$ . Judging whether the material is ductile or brittle depends on the value of  $B/G$ . If  $B/G > 1.75$ , the material is plastic; if the contrary, the material is brittle. In addition, it is straightforward to see from the ratios in Table 3 that all four materials are brittle, as these values are all less than the critical value (1.75). In addition, Poisson's ratio ( $\nu$ ) can also be used to measure the brittleness and toughness of materials. When  $\nu < 1/3$ , it is a brittle material; in addition, the material exhibits toughness. Table 3 shows that the Poisson's ratio of all four materials is less than 0.33. Likewise, Figure 4b can also prove that all four materials are brittle.

**Table 3.** Calculated bulk modulus  $B$  (in GPa), shear modulus  $G$  (in GPa), Poisson's ratio  $\nu$ , and Young's modulus  $E$  (in GPa) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

**Figure 4.** (a) Correlations between bulk modulus  $B$  (shear modulus  $G$ ) and Young's modulus ( $E$ ) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases; (b) Variations of  $G_H/B_H$  and  $\nu$  of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases. In graph (a), the values of bulk modulus and shear modulus are multiplied by the factor of 2 for a better comparison with Young's modulus.

### 3.4. Anisotropy in Elastic Moduli

Elastic anisotropy is commonly responsible for the formation and development of microcracks in materials. As a result, the elastic anisotropy of solids must be discussed, and this anisotropy is best defined by three indicators: the anisotropy index  $A^U$  [32], the percentage of compression anisotropy  $A_{\text{comp}}$ , and the percentage of shear anisotropy  $A_{\text{shear}}$  [33–35]. The calculation formula is as follows:

$$A^U = 5 \frac{G_V}{G_R} + \frac{B_V}{B_R} - 6 \quad (7)$$

$$A_{\text{comp}} = \frac{B_V - B_R}{B_V + B_R} \times 100\% \quad (8)$$

$$A_{\text{shear}} = \frac{G_V - G_R}{G_V + G_R} \times 100\% \quad (9)$$

$$A_1 = \frac{4C_{44}}{C_{11} + C_{33} - 2C_{13}} \quad (10)$$

$$A_2 = \frac{4C_{55}}{C_{22} + C_{33} - 2C_{23}} \quad (11)$$

$$A_3 = \frac{4C_{66}}{C_{11} + C_{22} - 2C_{12}} \quad (12)$$

Table 4 shows the anisotropy indices of the obtained ceramics of  $M_2\text{InX}$  phases. Figure 5 depicts the variation of  $A^U$  with  $A_{\text{shear}}$ . From Table 4, it can be seen that for  $\text{Ti}_2\text{InX}$  ( $X = \text{C}, \text{N}$ ), the  $A^U$  value of  $\text{Ti}_2\text{InC}$  (0.063) is smaller than that of  $\text{Ti}_2\text{InN}$  (0.042). For  $\text{Zr}_2\text{InX}$  ( $X = \text{C}, \text{N}$ ), the  $A^U$  value of  $\text{Zr}_2\text{InC}$  is smaller than that of  $\text{Zr}_2\text{InN}$ . Because the  $A^U$  value is proportional to the elastic anisotropy, the order of elastic anisotropy is  $\text{Ti}_2\text{InN} > \text{Ti}_2\text{InC}$  and  $\text{Zr}_2\text{InN} > \text{Zr}_2\text{InC}$ . It shows that  $\text{Ti}_2\text{InC}$  and  $\text{Zr}_2\text{InC}$  have better performance and lower possibility of microcracks.

**Table 4.** Calculated elastic anisotropic indexes ( $A^U$ ,  $A_{\text{comp}}$ ,  $A_{\text{shear}}$ ,  $A_1$ ,  $A_2$ ,  $A_3$ ) of  $M_2\text{InX}$  ( $M = \text{Ti}, \text{Zr}$  and  $X = \text{C}, \text{N}$ ) of MAX phases.

	$A^U$	$A_{\text{comp}}$ (%)	$A_{\text{shear}}$ (%)	$A_1$	$A_2$	$A_3$
$\text{Ti}_2\text{InC}$	0.053	0.004	0.005	0.851	0.851	1.000
$\text{Ti}_2\text{InN}$						
$\text{Zr}_2\text{InC}$	0.059	0.003	0.006	1.622	1.622	1.000
$\text{Zr}_2\text{InN}$						
$\text{Ti}_2\text{InC}$	0.034	0.001	0.004	1.072	1.072	1.000
$\text{Ti}_2\text{InN}$						
$\text{Zr}_2\text{InC}$	0.043	0.001	0.006	1.225	1.225	1.000
$\text{Zr}_2\text{InN}$						

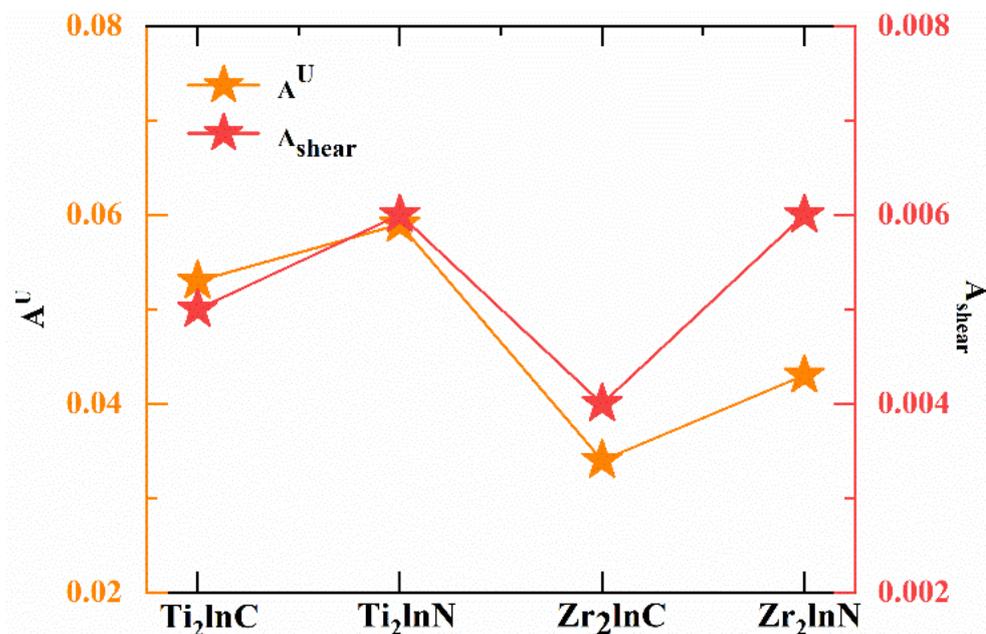

Figure 5. Variations of  $A^U$  and  $A_{shear}$  of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

$A_{comp}$  is used to reflect the compressible anisotropy of the material. From the data in Table 4, it can be seen that the  $A_{comp}$  value of  $Ti_2InC$  is the largest (0.004%), indicating that it has the strongest elastic anisotropy. In addition, it can be seen from  $A_{shear}$  that  $Ti_2InN$  (0.006) and  $Zr_2InN$  (0.006) have the highest shear elastic anisotropy. Meanwhile, from the  $A_{shear}$  value,  $Ti_2InC$  (0.005) and  $Zr_2InC$  (0.004) have the lowest anisotropy of shear modulus.  $A_1$  denotes shear anisotropy in the (100) plane,  $A_2$  shear anisotropy in the (010) plane, and  $A_3$  shear anisotropy in the (001) plane. Table 4 shows the  $|A_1 - 1|$  values of  $Ti_2InX$  ( $X = C, N$ ) and  $Zr_2InX$  ( $X = C, N$ ).  $Ti_2InN$  and  $Zr_2InN$  have the highest absolute values, respectively, indicating that the shear anisotropy is high. On the other hand,  $Ti_2InC$  and  $Zr_2InC$  have the lowest shear anisotropy on the (100) and (010) planes, respectively. The shear anisotropy results for  $A_1$  agree with those of  $A_{shear}$ . Therefore, the order of shear anisotropy is consistent with the order of elastic anisotropy. To sum up, the elastic anisotropy order of the  $M_2InX$  system is  $Ti_2InX > Zr_2InX$  ( $X = C, N$ ) and  $M_2InN > M_2InC$  ( $M = Ti, Zr$ ).

Crystal orientation, or the arrangement of crystal atoms in distinct crystal planes and orientations, can also influence elastic anisotropy. As a result, the elastic modulus anisotropy of the  $M_2InX$  phase is represented by the 3D surface structure using the following formula [36–38]:

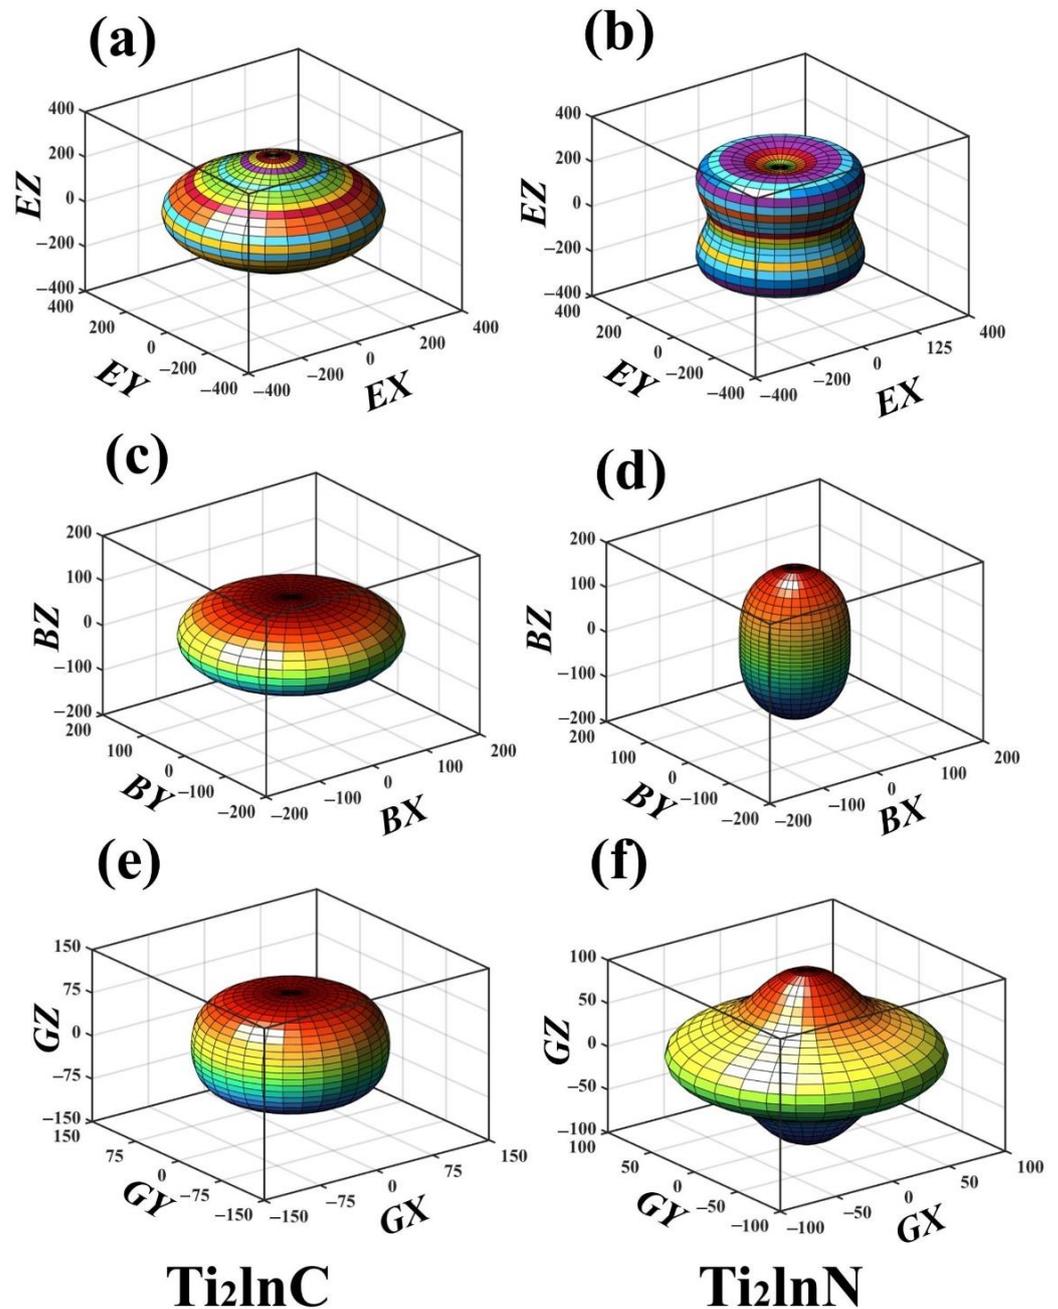

$$\frac{1}{B} = (S_{11} + S_{12} + S_{13}) - (S_{11} + S_{12} - S_{13} - S_{33})l_3^2 \quad (13)$$

$$\frac{1}{G} = S_{44} + \left[ (S_{11} - S_{12}) - \frac{1}{2}S_{44} \right] (1 - l_3^2) + 2(S_{11} + S_{33} - 2S_{13} - S_{44})l_3^2(1 - l_3^2) \quad (14)$$

$$\frac{1}{E} = S_{11}(1 - l_3^2)^2 + S_{33}l_3^4 + (2S_{13} + S_{44})l_3^2(1 - l_3^2) \quad (15)$$

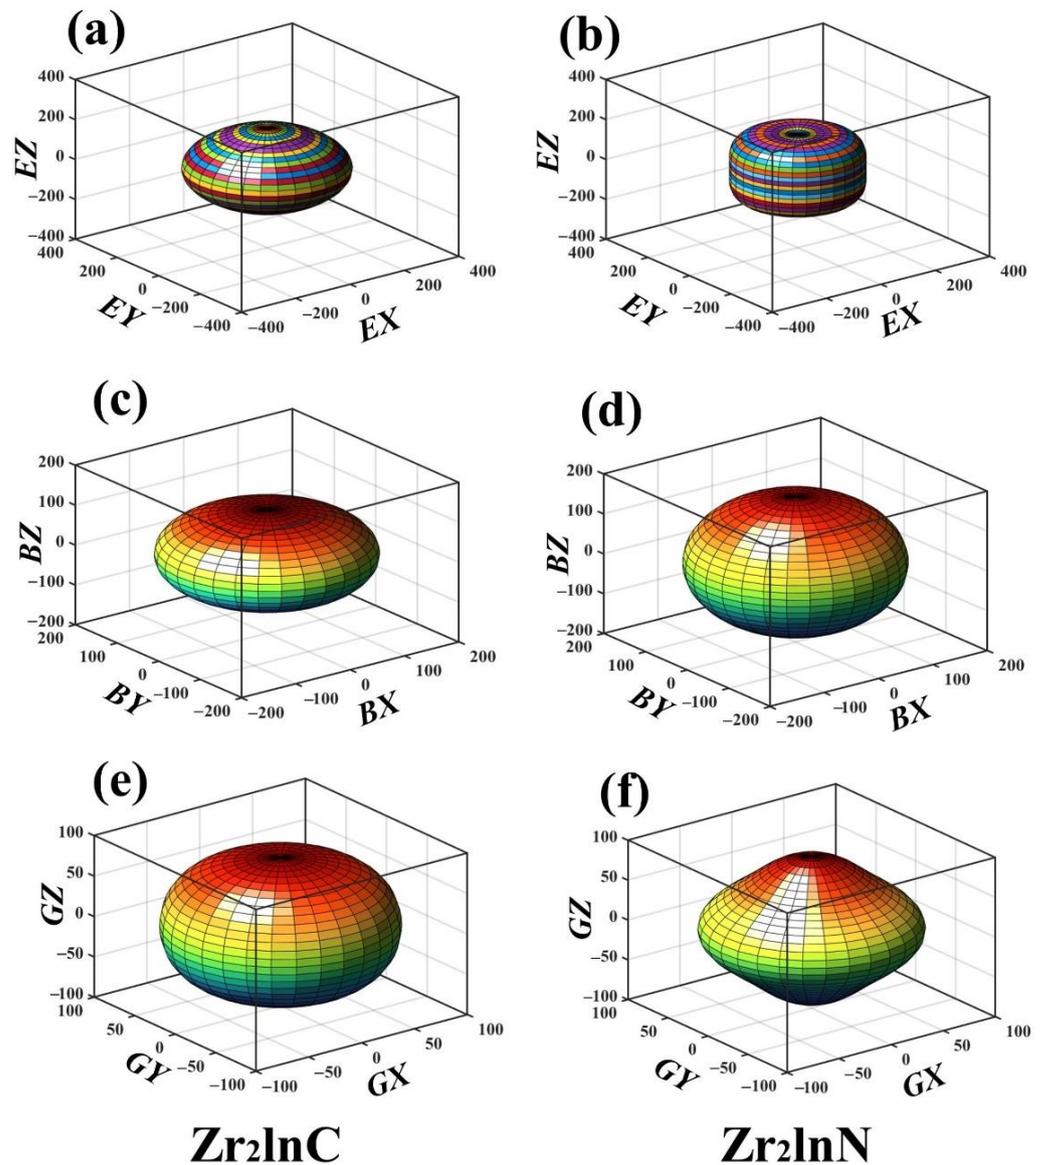

In this case,  $l_3$  represents the direction cosine.

Figures 6 and 7 display the 3D surface structures of  $Ti_2InC$ ,  $Ti_2InN$ ,  $Zr_2InC$ , and  $Zr_2InN$  in terms of  $E$ ,  $B$ , and  $G$ . Elastic isotropy may be described if the spherical 3D surface structure does not stray significantly from the sphere. Otherwise, it is anisotropic.

**Figure 6.** Three-dimensional surface constructions of  $E$  (a,b),  $B$  (c,d) and  $G$  (e,f) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases. The unit is GPa.

As can be seen from Figures 6 and 7, for bulk modulus, the 3D views of  $Ti_2InC$  and  $Zr_2InC$  show significant compression along the  $c$ -axis, while the 3D views of  $Ti_2InN$  and  $Zr_2InN$  show significant compression along the  $a$ - and  $b$ -axes. Combined with the data analysis in Table 5, the  $B[100]/B[1]$  values of  $Ti_2InC$ ,  $Zr_2InC$ ,  $Ti_2InN$ , and  $Zr_2InN$  have a large deviation from 1, which can also indicate that the materials are anisotropic.

**Figure 7.** Three-dimensional surface constructions of  $E$  (a,b),  $B$  (c,d) and  $G$  (e,f) of  $Zr_2lnX$  ( $X = C, N$ ) MAX phases. The unit is GPa.

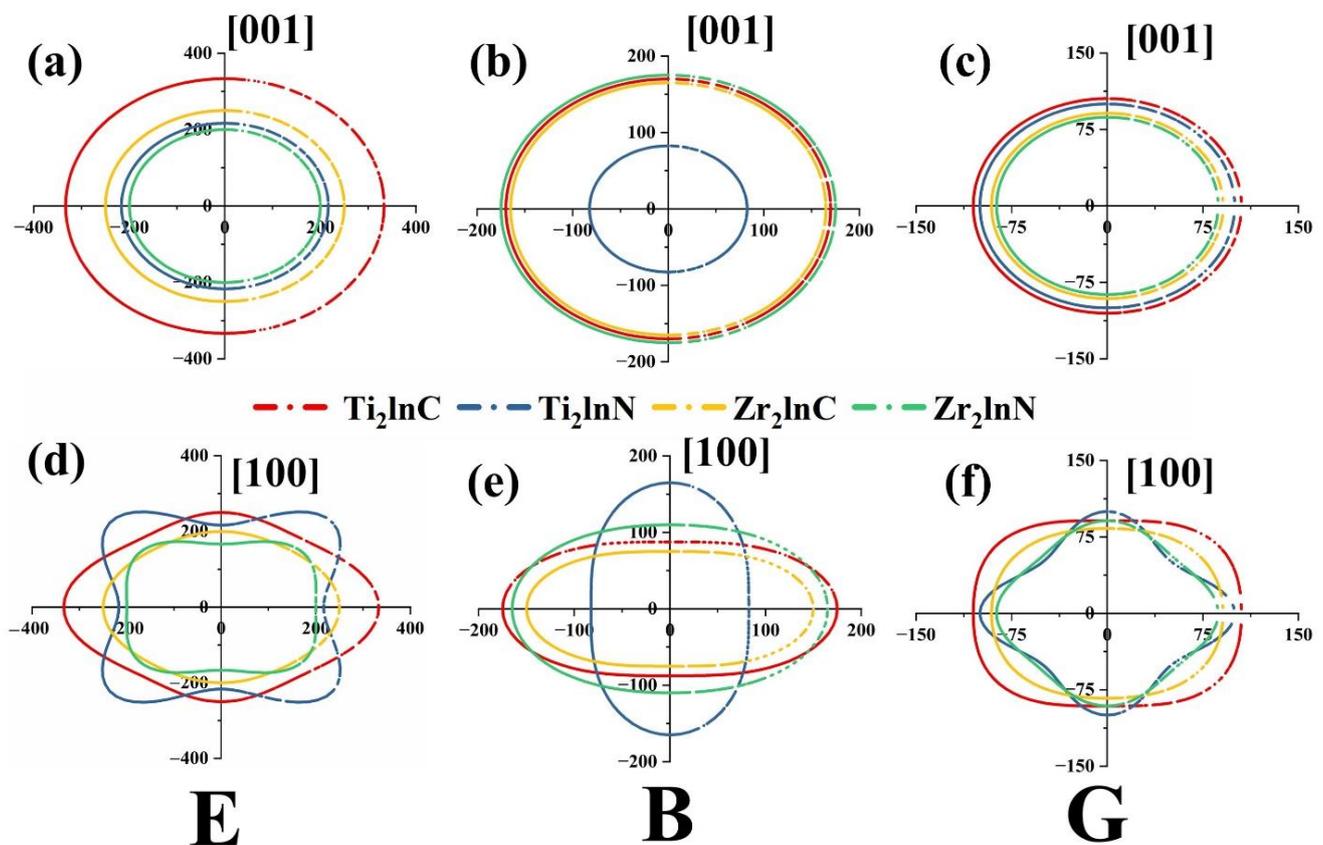

**Table 5.** Calculated uniaxial elastic moduli in the [100], [10] and [1] directions (in GPa) of  $M_2lnX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

		Ti <sub>2</sub> lnC	Ti <sub>2</sub> lnN	Zr <sub>2</sub> lnC	Zr <sub>2</sub> lnN
$E$	[1]	304	205	211	174
	[10]	309	216	215	174
	[100]	309	216	215	180
	[100]/[1]	1.02	1.05	1.02	1.04
$B$	[1]	160	86	156	163
	[10]	172	163	160	170
	[100]	172	163	160	170
	[100]/[1]	1.08	1.90	1.03	1.04
$G$	[1]	122	118	112	80
	[10]	125	122	115	84
	[100]	125	122	115	84
	[100]/[1]	1.02	1.03	1.03	1.05

When the shear moduli of  $\text{Ti}_2\text{InN}$  and  $\text{Zr}_2\text{InN}$  are compared to those of a spherical shape, it is obvious that their shapes are considerably different. As a result,  $\text{Ti}_2\text{InN}$  and  $\text{Zr}_2\text{InN}$  shear moduli are anisotropic.  $\text{Ti}_2\text{InN}$  and  $\text{Zr}_2\text{InN}$  shear moduli also are anisotropic, and the anisotropy order is  $\text{Ti}_2\text{InN} > \text{Ti}_2\text{InC}$  and  $\text{Zr}_2\text{InC} > \text{Zr}_2\text{InN}$ .  $\text{Ti}_2\text{InN}$  has a substantially higher degree of shear anisotropy than  $\text{Zr}_2\text{InN}$ . At the same time, this conclusion is compatible with the previously reported order of percent shear anisotropy. When compared to bulk and shear modulus, Young's modulus  $E$  considers both bulk modulus  $B$  and shear modulus  $G$ . The 3D plots of the Young's modulus of  $\text{M}_2\text{InX}$  ( $M = \text{Ti}, \text{Zr}$  and  $X = \text{C}, \text{N}$ ) MAX phases are more compressible along the  $a$ - and  $b$ -axes than the  $c$ -axis, as shown in Figures 6 and 7.  $\text{Ti}_2\text{InN}$  is more anisotropic than  $\text{Ti}_2\text{InC}$ , whereas  $\text{Zr}_2\text{InN}$  is more anisotropic than  $\text{Zr}_2\text{InC}$ .

The three-dimensional elastic modulus graph shows that  $\text{Ti}_2\text{InN}$  and  $\text{Zr}_2\text{InN}$  are elastically anisotropic, with  $\text{Ti}_2\text{InN}$  having more elastic anisotropy than  $\text{Zr}_2\text{InN}$ . This is consistent with the  $A^U$  value results presented above.

To further illustrate the elastic anisotropy of  $\text{M}_2\text{InX}$  ( $M = \text{Ti}, \text{Zr}$  and  $X = \text{C}, \text{N}$ ) MAX phases, Figure 8 plots the 2D projections of the elastic modulus of the  $\text{M}_2\text{InX}$  system on crystal planes (001) and (100), respectively. Based on Figure 8, Table 5 shows the elastic modulus of the  $\text{M}_2\text{InX}$  phases. As can be shown in Table 5, the  $G[100]/G[1]$  values of  $\text{Ti}_2\text{InC}$  and  $\text{Ti}_2\text{InN}$  are 1.02 and 1.03, respectively, indicating that there is a divergence between  $G[100]/G[1]$  and 1, indicating that the material has a greater shear modulus and anisotropy. As a result,  $\text{Ti}_2\text{InN}$  has the largest shear modulus anisotropy, followed by  $\text{Ti}_2\text{InC}$ , showing that the order of anisotropy of  $G$  is  $\text{Ti}_2\text{InN} > \text{Ti}_2\text{InC}$ .  $\text{Zr}_2\text{InC}$  and  $\text{Zr}_2\text{InN}$  have  $G[100]/G[1]$  values of 1.03 and 1.05, respectively, showing that the anisotropic order of  $G$  is  $\text{Zr}_2\text{InN} > \text{Zr}_2\text{InC}$ . This is consistent with the results of  $A_1$  above.

**Figure 8.** Projections of  $E$  (a,b),  $B$  (c,d) and  $G$  (e,f) of  $\text{M}_2\text{InX}$  ( $M = \text{Ti}, \text{Zr}$  and  $X = \text{C}, \text{N}$ ) MAX phases. The unit is GPa.

The  $E[100]/E[1]$  values of  $Ti_2InC$  and  $Ti_2InN$  are 1.02 and 1.05, respectively, as shown in Table 5.  $Zr_2InC$  and  $Zr_2InN$  have  $E[100]/E[1]$  values of 1.02 and 1.04, respectively. As a result, the anisotropic order of  $E$  is  $Ti_2InN > Ti_2InC, Zr_2InN > Zr_2InC$ . This is consistent with the  $A^U$  results.

The expected values of the bulk modulus along the [100] and [10] directions are significantly larger than those along the [1] direction. As shown in Table 5, the  $B[100]/B[1]$  values of  $Ti_2InC$  and  $Ti_2InN$  are 1.08 and 1.90, respectively. The  $B[100]/B[1]$  values of  $Zr_2InC$  and  $Zr_2InN$  are 1.03 and 1.04, respectively. It can be seen that  $Ti_2InN$  has the largest anisotropy, which can be clearly perceived in combination with the 2D diagram, showing that the compression ratio along the  $c$ -axis is smaller than the  $a$ -axis and  $b$ -axis compression [39,40].

### 3.5. Debye Temperatures and Anisotropy of Sound Velocities

The Debye temperature ( $\theta_D$ ) is a fundamental thermodynamic property of a solid. The Debye temperature is commonly used to characterize a material's thermal properties, which may be computed using the single crystal elastic constant [41]:

$$\theta_D = \frac{h}{k_B} \left[ \frac{3n}{4\pi} \left( \frac{N_A \rho}{Mc} \right) \right]^{\frac{1}{3}} v_m \quad (16)$$

$N_A$  stands for Avogadro's constant,  $k_B$  is Boltzmann's constant, and  $h$  is Planck's constant. the total number of atoms in the unit cell is represented by  $n$ .  $M$  stands for molecular weight,  $\rho$  is density, and  $v_m$  represents the average sound velocity, which is determined by the longitudinal and transverse sound velocities, as shown in the following equation [42,43]:

$$v_l = \left[ \left( B + \frac{4G}{3} \right) / \rho \right]^{\frac{1}{2}} \quad (17)$$

$$v_t = \left( \frac{G}{\rho} \right)^{\frac{1}{2}} \quad (18)$$

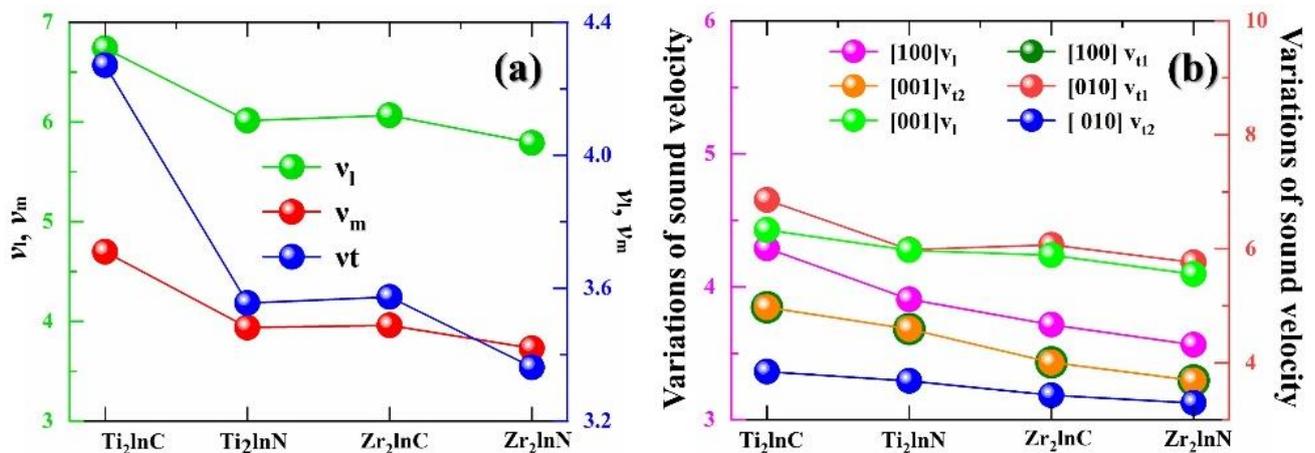

$$v_m = \left[ \frac{1}{3} \left( \frac{2}{v_t^3} + \frac{1}{v_l^3} \right) \right]^{-\frac{1}{3}} \quad (19)$$

Table 6 shows the calculated values of  $v_l$ ,  $v_t$ ,  $v_m$ , and  $\theta_D$  for the compounds. In general, the greater the density, the slower the sound speed. Due to the higher densities of  $Ti_2InN$  and  $Zr_2InN$  ( $6.389 \text{ g/cm}^3$  for  $Ti_2InN$  and  $7.302 \text{ g/cm}^3$  for  $Zr_2InN$ ), their sound velocities are relatively slow in Table 6.

**Table 6.** The density  $\rho$ , sound velocities (longitudinal  $v_l$ , transverse  $v_t$ , and mean  $v_m$ ), and Debye temperature  $\theta_D$  of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

$TM_5Al_3C$	$\rho$ ( $\text{g/cm}^3$ )	$v_l$ (km/s)	$v_t$ (km/s)	$v_m$ (km/s)	$\theta_D$ (K)	Ref.
$Ti_2InC$	6.079	6.738	4.271	4.697	564	This work
$Ti_2InN$	6.389	6.013	3.555	3.938	480	This work
$Zr_2InC$	6.949	6.066	3.573	3.960	446	This work
$Zr_2InN$	7.302	5.791	3.362	3.731	426	This work
		5.770	3.297		423	Theo. [23]

Figure 9a shows the variation in different sound velocities.  $Ti_2InC$  has the highest Debye temperature due to its low density and high elastic modulus, and  $Zr_2InN$  has the lowest Debye temperature due to its high density and low elastic modulus. As we all know, the Debye temperature is commonly employed to reflect the strength of chemical bonds and the hardness of materials. As a result, the higher the Debye temperature, the stronger the chemical bond and the harder the solid.

**Figure 9.** (a) Variations in sound velocity of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases; (b) Directional sound velocity of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

It can be shown that Ti<sub>2</sub>InC has the highest Debye temperature (564 K), suggesting that its chemical bond is the strongest, while Zr<sub>2</sub>InN has the lowest (426 K), showing that its chemical bond is the weakest. At the same time, it can be demonstrated that Ti<sub>2</sub>InC has the highest hardness and Zr<sub>2</sub>InN has the lowest. This confirms the previous section's conclusion about the materials' strength and hardness based on the elastic constant.

In addition, there is a certain proportional relationship between Debye temperature and thermal conductivity, so the higher the Debye temperature of the material, the greater the thermal conductivity, which is consistent with the literature [44–46]. Therefore, Ti<sub>2</sub>InC has the largest Debye temperature and thus exhibits the largest thermal conductivity.

The transverse sound velocity has two modes:  $v_{t1}$  (first transverse mode) and  $v_{t2}$  (second transverse mode). The directional sound velocity calculation results of  $M_2InX$  phases are shown in Table 7. Table 7 shows that the first transverse sound velocity ( $[10]v_{t1}$ ) of the  $M_2InX$  system along the  $[100]$  direction is the greatest, followed by the first longitudinal sound velocity ( $[1]v_l$ ). The directional sound velocity is well-known to be related to the elastic constants ( $C_{11}$ ,  $C_{33}$ ,  $C_{44}$ ). As a result, Figure 9b shows the relationship between the elastic constants of sound velocity in different directions for the  $M_2InX$  phases. All sound speeds are obviously anisotropic in both Ti<sub>2</sub>InX ( $X = C, N$ ) and Zr<sub>2</sub>InX ( $X = C, N$ ) systems due to the shift in sound speed direction. It is also demonstrated that the link between sound speed and elastic constant is consistent. For example, the initial transverse sound velocity ( $[10]v_{t1}$ ) along the  $[100]$  direction is related to  $C_{11}$ , for which the order is Ti<sub>2</sub>InC > Zr<sub>2</sub>InC > Ti<sub>2</sub>InN > Zr<sub>2</sub>InN. Similarly, the change trend of  $[1]v_l$  matches that of  $C_{33}$ , and the change trend of  $[1]v_{t2}$ ,  $[100]v_{t1}$ , and  $[10]v_{t2}$  matches that of  $C_{44}$ .  $[100]v_l$  is associated with  $C_{11}-C_{12}$ . Therefore, Figure 9b plots the relationship between different sound velocities for  $M_2InX$  phases.

**Table 7.** Anisotropic sound velocities (m/s) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

### 3.6. Thermal Properties

Generally speaking, the thermal properties of materials are usually characterized by thermal conductivity, heat capacity, and thermal expansion coefficient. Thermal conductivity is a measure of the thermal conductivity of a substance. The lattice thermal conductivity

$k_{ph}$  is one of the most important indicators to describe the thermal behavior of solids. Therefore, according to Slack's model [47], the lattice thermal conductivity of  $M_2InX$  phases can be calculated with the following empirical formula:

$$k_{ph} = A \frac{M_{av} \delta \theta_D^3}{\gamma^2 T n^{2/3}} \quad (20)$$

Here, the volume of each atom is denoted by  $\delta^3$ . The average atomic mass of each atom is denoted by  $M_{av}$ ,  $T$  is the temperature, and  $n$  is the number of atoms in the unit cell.  $\gamma$  is the Grüneisen parameter that can be obtained from Poisson's ratio  $\nu$ , while  $A_\gamma$  is the component associated with  $\gamma$ , and the formulas are as follows [48]:

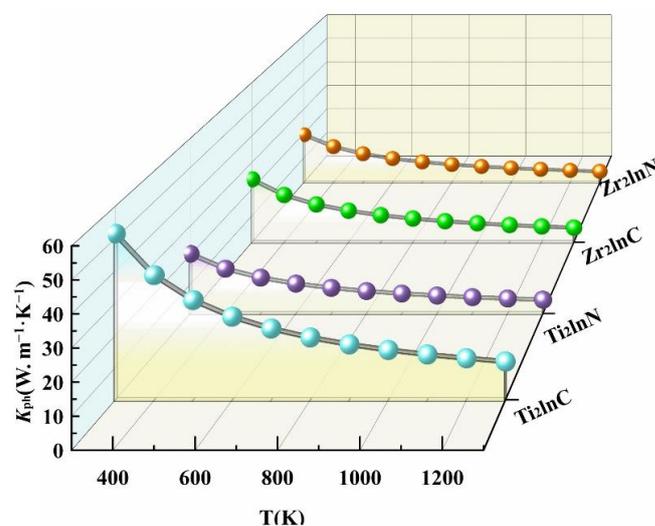

$$\gamma = \frac{3(1 + \nu)}{2(2 - 3\nu)} \quad (21)$$

$$A_\gamma = \frac{5.720 \times 10^7 \times 0.849}{2 \times \left(1 - \frac{0.154}{\gamma} + \frac{0.228}{\gamma^2}\right)} \quad (22)$$

The lattice thermal conductivities of  $Ti_2InC$ ,  $Ti_2InN$ ,  $Zr_2InC$ , and  $Zr_2InN$  at two temperatures (300 K and 1300 K) are shown in Table 8. The results show that most of the  $M_2AX$  phases have thermal conductivities ranging from 12 to 60  $W \cdot m^{-1}$  [49]. The calculation result is within this range. The lattice thermal conductivities of  $Ti_2InC$ ,  $Ti_2InN$ ,  $Zr_2InC$ , and  $Zr_2InN$  at room temperature (300 K) are 51.48, 20.43, 23.59, and 19.42  $W \cdot m^{-1} \cdot K^{-1}$ , respectively. Therefore,  $Ti_2InC$ ,  $Ti_2InN$ ,  $Zr_2InC$ , and  $Zr_2InN$  can serve as potential thermal conductive materials at room temperature. As shown in Figure 10, as the temperature increases,  $k_{ph}$  decreases rapidly and then tends to a limit value. In the temperature range of 300 K–1300 K, the order of  $k_{ph}$  is  $Ti_2InC > Zr_2InC > Ti_2InN > Zr_2InN$ .

**Table 8.** Calculated  $\delta$  (in Å),  $M_{av}$  (in kg/mol), Grüneisen parameter  $\gamma$ ,  $A_\gamma$  ( $\times 10^{-8}$ ), and lattice thermal conductivities  $k_{ph}$  (in  $W \cdot m^{-1} \cdot K^{-1}$ ) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases.

	$\delta$	$M_{av}$	$\gamma$	$n$	$A_\gamma$	$k_{ph}$ (300 K)	$k_{ph}$ (1300 K)	$k_{min}$
$Ti_2InC$	2.48	55.66	1.16	8.00	3.34	51.48	11.88	1.23
$Ti_2InN$	2.44	56.16	1.41	8.00	3.24	20.43	4.72	1.12
$Zr_2InC$	2.60	77.31	1.43	8.00	3.23	23.59	5.44	0.96
$Zr_2InN$	2.64	77.81	1.48	8.00	3.21	19.42	4.48	0.94

**Figure 10.** Lattice thermal conductivities  $k_{ph}$  of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases in the temperature range of 300 K–2000 K.

The thermal conductivity is mainly derived from the lattice thermal conductivity at the ground state temperature. Therefore, the thermal conductivity reflection of ceramics can be characterized as the minimum thermal conductivity [50]. Consequently, the Clark model is used here to calculate the minimum thermal conductivity  $k_{\min}$  of the  $M_2InX$  system, and the expression is as follows:

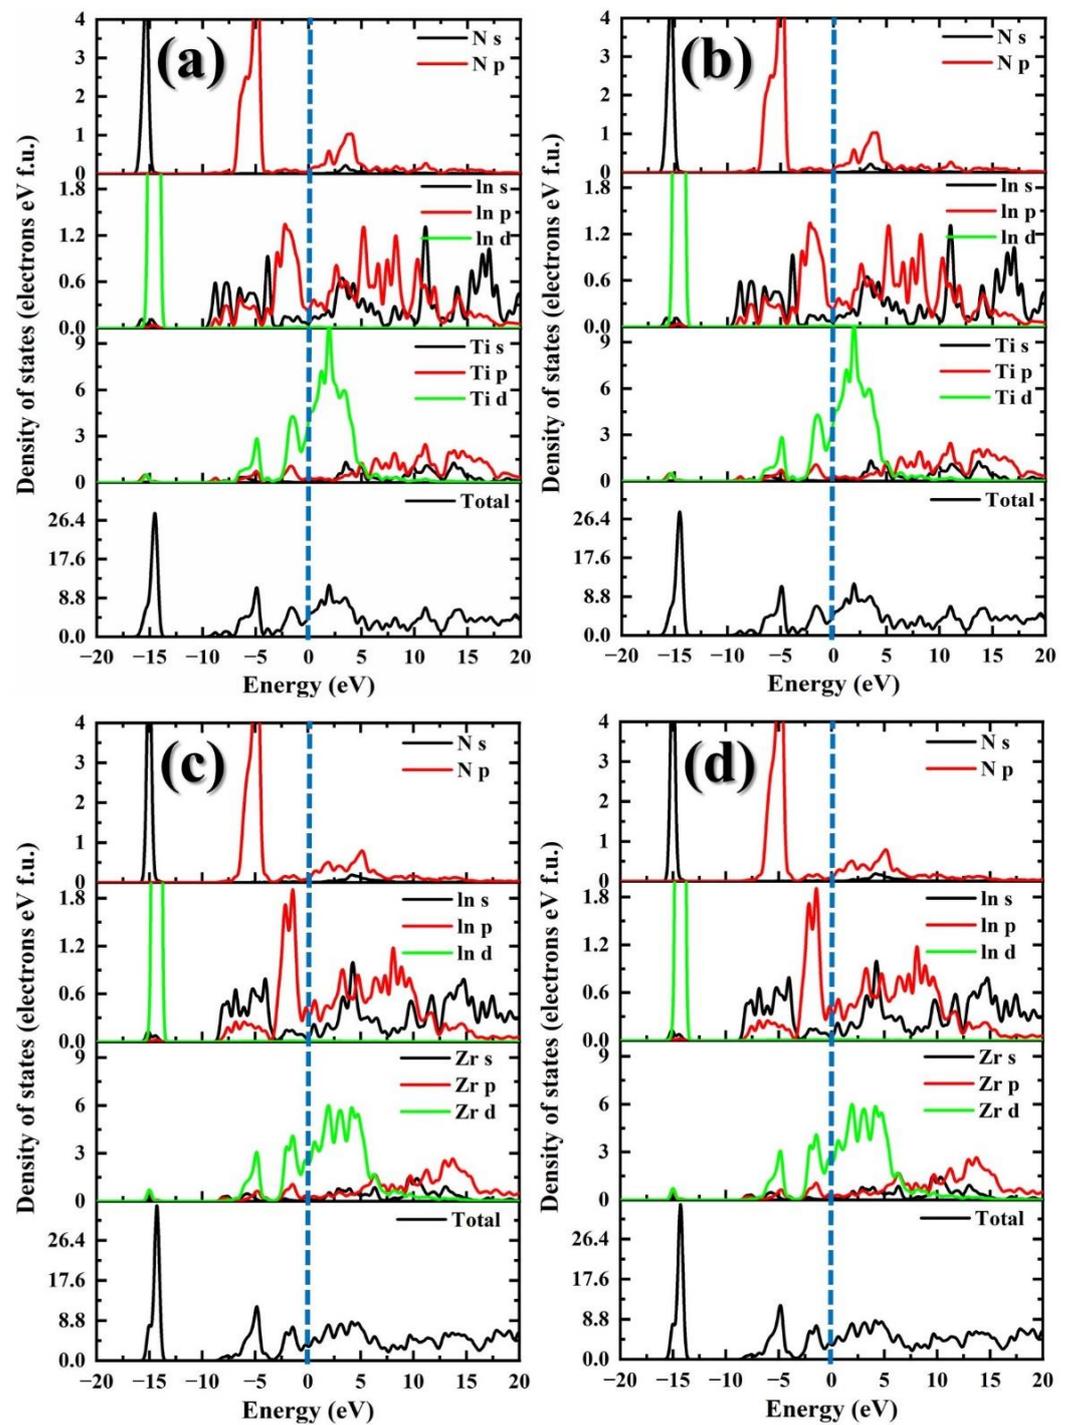

$$k_{\min} = K_B V_m \left( \frac{n \rho N_A}{M} \right)^{\frac{2}{3}} \quad (23)$$

Table 8 shows the calculated minimum lattice thermal conductivities for the  $M_2InX$  system. It can be seen from Table 8 that the  $k_{\min}$  of  $M_2InX$  are 1.23, 1.12, 0.96, and 0.94  $W \cdot m^{-1} \cdot K^{-1}$ , respectively. The difference between the lattice thermal conductivity and  $\theta_D$  is that the higher Debye temperature has a larger lattice thermal conductivity, so  $Ti_2InC$  has the largest thermal conductivity, which corresponds to the highest Debye temperature (564 K) of  $Ti_2InC$ . Furthermore, the calculated order of minimum thermal conductivity is  $Ti_2InC > Ti_2InN > Zr_2InC > Zr_2InN$ . As is known,  $M_2InX$  phases are not potential high-temperature thermal barrier coatings when compared with  $Ln_2Zr_2O_7$  ( $1.2 \sim 1.4 W \cdot m^{-1} \cdot K^{-1}$ ) [51]. The thermal conductivity of new ceramic materials is between  $1.2 W \cdot m^{-1} \cdot K^{-1} \sim 1.6 W \cdot m^{-1} \cdot K^{-1}$ . Among these compounds, the thermal conductivity of  $Ti_2InC$  is within this range, so  $Ti_2InC$  may become a potential insulating material [52].

### 3.7. Electronic Properties

The electronic properties (density of states) of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases were studied to better understand chemical bonding and bond behaviors. Figure 11 depicts the  $M_2InX$  phases' total density of states (TDOS) and partial density of states (PDOS). To begin, it is clear that DOS has a significant finite value at the Fermi level, indicating that these compounds exhibit metallic conductivity. Figure 11 shows that the total density of states ( $E_f$ ) value of  $Ti_2InN$  and  $Zr_2InN$  is greater than that of  $Ti_2InC$  and  $Zr_2InC$ , indicating that  $Ti_2InN$  and  $Zr_2InN$  are more conductive than  $Ti_2InC$  and  $Zr_2InC$ . Secondly, the peak topologies and relative heights of the peaks around  $E_f$  in the TDOS plot are highly comparable, indicating the presence of similar chemical bonds in  $Zr_2AN$ . The time difference around the Fermi level is mostly made up of  $In-p$  and  $M-d$  states. The time difference below the Fermi energy is caused mostly by the  $X-s$ ,  $M-s$ , and  $M-p$  states, whereas the time difference above the Fermi energy is caused primarily by the  $In-s$  and  $X-p$  states. As shown in Figure 11, the  $In-p$ ,  $M-d$ , and  $X-p$  states exhibit substantial hybridization, allowing  $M-C$  and  $M-N$  chemical bonds to form, resulting in the high elastic modulus of  $M_2InX$ . PDOS exhibits multiple hybridizations of the electronic states  $M$ ,  $In$ , and  $X$ . The valence band of  $M_2InX$  in Figure 11 displays substantial hybridization of the  $M-d$  and  $X-p$  states, as predicted for covalent compounds. The  $d-p$  hybrid state corresponding to the  $M-In$  bond was discovered to be in a greater energy range than the  $M-X$  bond. As a result, the  $M-X$   $d-p$  hybridization helps to maintain the crystal structure. Finally, it is demonstrated that  $M$ 's electronic charge density almost overlaps that of  $In$ , indicating that the bonding between  $M$  and  $In$  is quite weak. These findings are consistent with the observation that the biggest phase features very strong  $M-X$  bonds and very weak  $M-In$  bonds.

As can be seen from Table 9, the  $M$  atom loses electrons, while the  $In$  and  $X$  atoms gain electrons. Among them, for the  $Ti_2InX$  system, the  $Ti-C$  bond has the largest BP value, indicating that the  $Ti-C$  bond has a strong chemical bond. Therefore, it is proved that  $Ti_2InC$  has the strongest chemical bond and  $Ti_2InN$  has the weakest chemical bond. For the  $Zr_2InX$  system, it can also be stated that  $Zr_2InC$  has the strongest chemical bond and  $Zr_2InN$  has the weakest chemical bond. The  $M$  and  $X$  atoms form a strongly directed  $M-X$  covalent bond originating from the hybrid  $M d-X p$  state. These results are also consistent with the finding that the largest phase typically has very strong  $M-X$  bonds and relatively weak  $M-A$  bonds.

#### 4. Conclusions

In summary, this work uses first-principles calculations to estimate the anisotropic elastic and thermal properties of  $M_2InX$  ( $M = Ti, Zr$  and  $X = C, N$ ) MAX phases. The structural properties and elastic constants of the obtained  $M_2InX$  phases are in agreement with the results reported in the literature, the obtained data are quite reliable, and the  $M_2InX$  phase's mechanical stability has been studied. According to the elastic constants,  $Ti_2InC$  and  $Zr_2InC$  are more incompressible along the *a*- and *b*-axes, while  $Ti_2InN$  and  $Zr_2InN$  are more compressible along the *a*- and *b*-axes. For all  $M_2InX$  phase materials, shear modulus is a better measure of hardness than bulk modulus. Therefore,  $Ti_2InC$  has high hardness and can be used to make superhard materials. The anisotropic elasticity of the  $M_2InX$  phase is  $Ti_2InN > Ti_2InC$ ,  $Zr_2InN > Zr_2InC$ , based on  $A^U$ ,  $A_{comp}$ , and  $A_{shear}$  values, 3D graphs, and 2D projection analysis. In addition,  $Ti_2InC$  has the highest speed of sound (4.697) and Debye temperature (564 K), while  $Zr_2InN$  has the lowest speed of sound (3.731) and Debye temperature (426 K). Meanwhile,  $Ti_2InC$  may become a potential insulation material. The electronic properties of the  $M_2InX$  phase were investigated, and the presence of strong M-X *d-p* hybridization helps to maintain the crystal structure.
