In total, 56 sequences form 35 sequence pairs that share 99% or greater sequence identity. Sequences are named by sample number followed by contig number. These represent identical or near identical sequences found in different study subjects, on different dates and in some cases different study site locations. Sequence pairs outlined with a bold border are from different study sites, with Kisumu sequences in the range of 10001 to 10450, and Siaya sequences represented by sample numbers > 10450.

Univariate linear regression analyses with continuous (linear regression) and categorical (logistic regression) variables as dependent variable and motif numbers at the patient level as predictors. Statistically significant results ($p < 0.05$) are bolded; trending results ($0.05 < p < 0.1$) are italicized.

Among categorical variables gravidity group tests multigravid status, parasitemia and hemozoin analyses test presence in the upper quartile, histology group tests chronic PM, anemia tests hemoglobin < 11 g/dL, HIV tests HIV seropositivity, self-reported antimalarial drug use tests reported use of drugs, low birth weight tests birth weight ≤ 2500 g, and preterm birth tests gestational age < 37 weeks.

^a determined as summarized in Table 1 and Methods; parasitemia analyses done using log-transformed data. Percent placental parasitemia analysis omits one multigravida for whom a placental thin smear was unavailable.

^b percent of white blood cells on a thick smear bearing phagocytosed hemozoin; log transformed data.

^c data are missing for 16 clients.

^d analysis omits six patients for whom histological analysis was unavailable.

^e reported use of antipyretics is categorized as no antimalarial drug use.

Univariate regression analysis with group membership as dependent variable and continuous (linear regression) and categorical (logistic regression) variables as predictors. Statistically significant results are bolded; trending results are italicized.

OR (CI) = Odds Ratio (95% confidence interval). NA = not applicable. Results with $p < 0.05$ are bolded and results with $0.05 < p < 0.1$ are italicized. All results with $p < 0.1$ are presented graphically in Figure 4A.

Among categorical variables gravidity group tests multigravid status, parasitemia and hemozoin analyses test presence in the upper quartile, histology group tests chronic PM, anemia tests hemoglobin < 11 g/dL, HIV tests HIV seropositivity, self-reported antimalarial drug use tests reported use of drugs, low birth weight tests birth weight ≤ 2500 g, and preterm birth tests gestational age < 37 weeks.

^a determined as summarized in Table 1 and Methods; parasitemia analyses done using log-transformed data. Percent placental parasitemia analysis omits one multigravida for whom a placental thin smear was unavailable.

^b percent of white blood cells on a thick smear bearing phagocytosed hemozoin; log transformed data.

^c data are missing for 16 clients.

^d analysis omits six patients for whom histological analysis was unavailable.

^e reported use of antipyretics is categorized as no antimalarial drug use.

Table S6. Multiple logistic regression analysis of sequence type dominance.

Multiple regression analysis with group membership as dependent variable and continuous (linear regression) and categorical (logistic regression) variables as predictors. Statistically significant results are bolded; trending results are italicized.

OR (CI) = Odds Ratio (95% confidence interval). NA = not applicable. Results with $p < 0.05$ are bolded and results with $0.05 < p < 0.1$ are italicized. Analyses considered variables with $p < 0.1$ in univariate analysis, and all outcomes are shown in Figure 4B.

^a determined as summarized in Table 1 and Methods; parasitemia analyses done using log-transformed data.

^b percent of white blood cells on a thick smear bearing phagocytosed hemozoin; log transformed data.

^c analysis omits six patients for whom histological analysis was unavailable.

^d reported use of antipyretics is categorized as no antimalarial drug use.

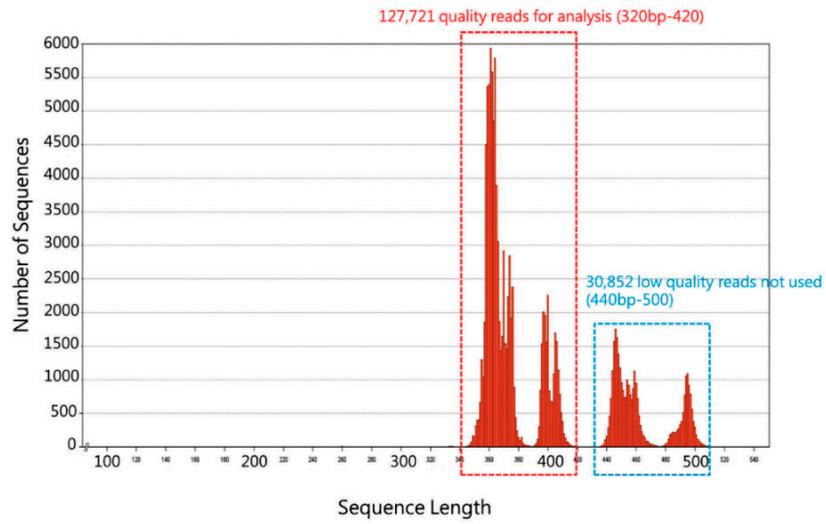

Figure S1. Summary of total number of quality reads used. Shown on the x-axis is the total number of sequences and y-axis the sequence lengths in base pairs (bp).

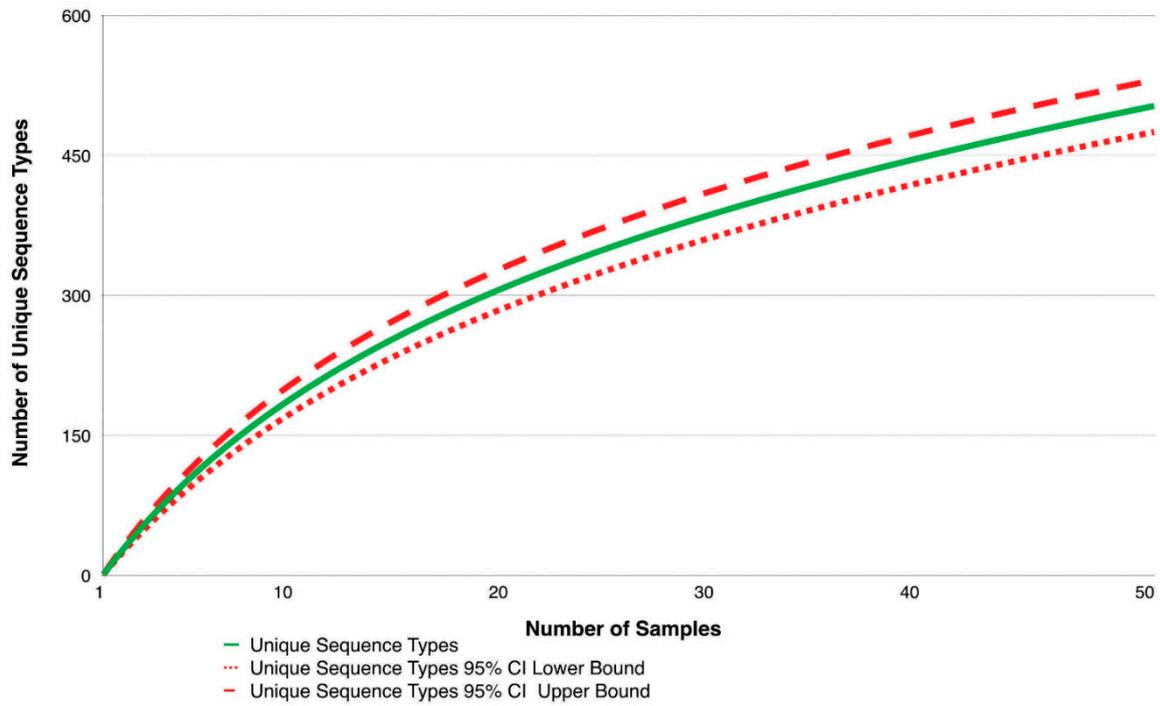

Figure S2. Rarefaction curve of *var2csa* unique sequence types for entire study population (N = 49). The computed rarefaction curve (in solid green) shows the expected average rate of unique sequence types that would be produced as a result of repeated deep sequencing. Upper and lower 95% confidence intervals (CI) for species richness are shown by dashed and dotted red lines, respectively.

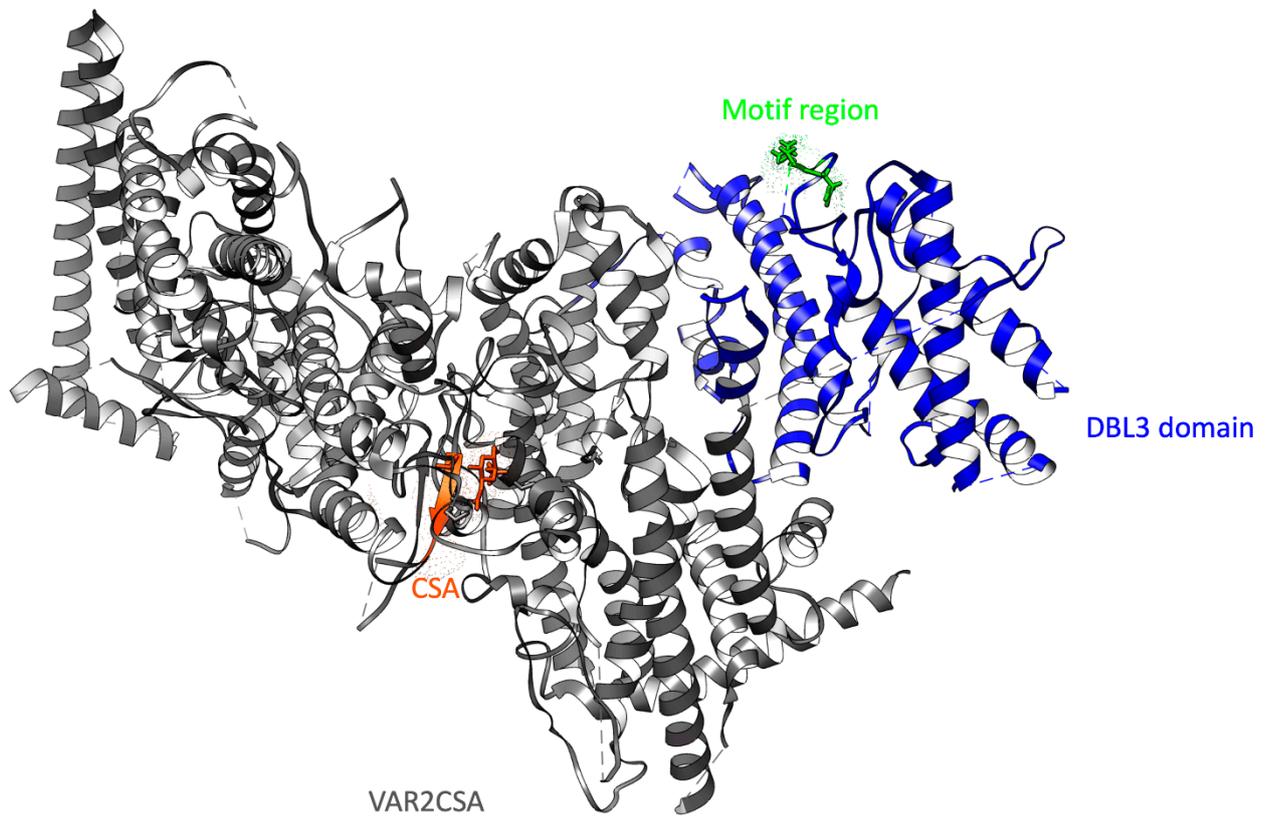

Figure S3. VAR2CSA and DBL3X motif region. A ribbon representation of VAR2CSA (grey), DBL3X domain (blue). Dotted circles and atom stick representation show the CSA binding site (orange) and specific motif region (green) associated with gravidity and placental malaria outcomes.

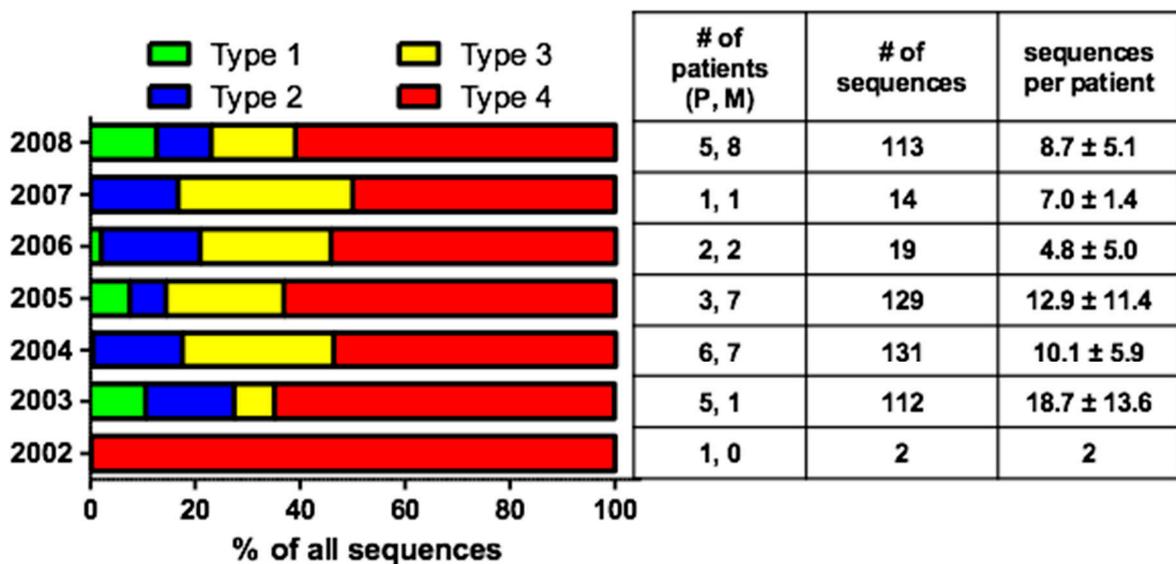

Figure S4. DBL3X sequence types are consistently found independently of time and location of patient recruitment. The graph depicts proportional distribution of sequence types by year of patient recruitment. The table at right summarizes number of patients recruited each year (stratified by gravidity group), number of unique sequences contributed by those patients, and the mean number of unique sequences per patient.

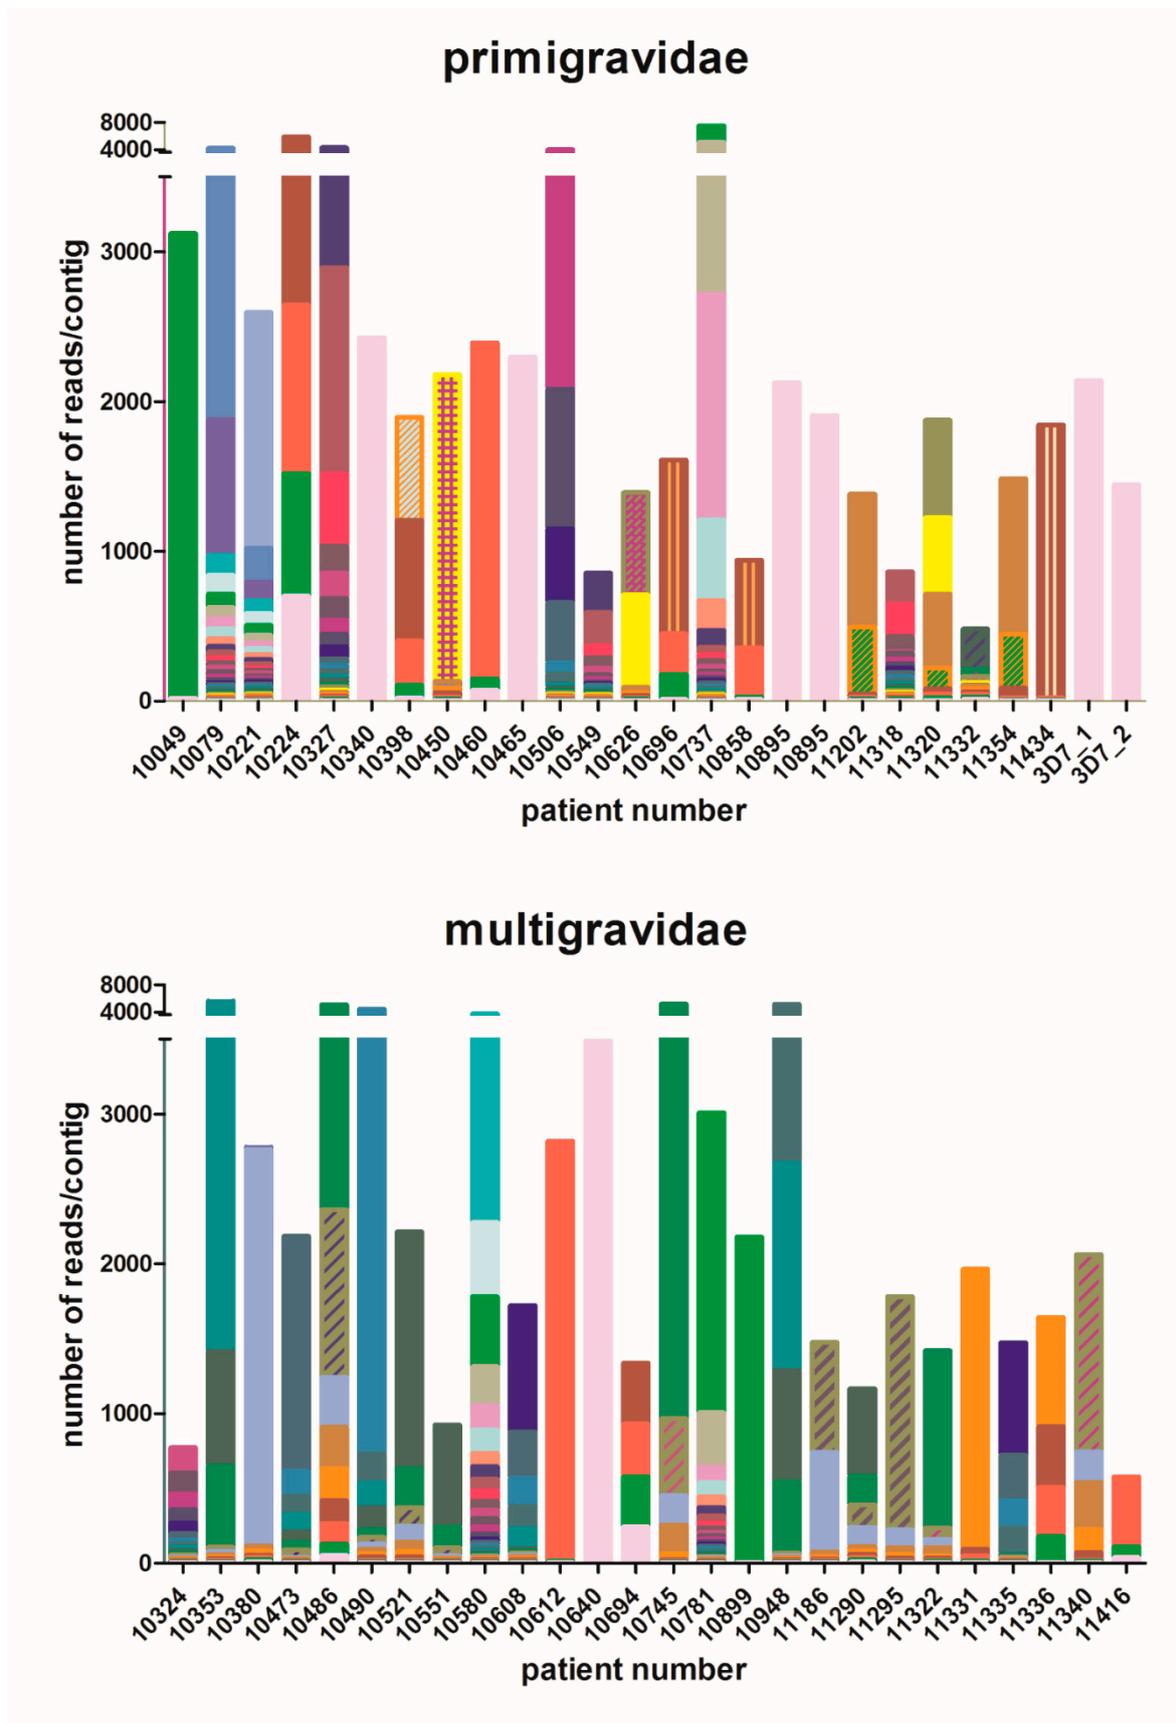

Figure S5. Unique DBL3X sequences are not proportionally represented at the individual patient level. The graphs depict the number of unique contigs within each patient. Notably, most patients have a single dominant contig. Patient 895 is depicted twice, representing two separate deep sequencing runs. This patient was previously identified (REF) as having a single unique sequence. DNA from the clonal laboratory isolate, 3D7, was also included as a control, and shows, in two

separate runs, a single contig. Similar colors across individual patients do *not* imply sequence similarity.

Next Generation Sequencing: Method(s)
