

Evolutionary insight into the Trypanosomatidae using alignment-free phylogenomics of the kinetoplast

Alexa Kaufer ^{1,*}, Damien Stark ² and John Ellis ¹

Supplementary Materials S1 – S5

S1 – Table of all trypanosomatid species used in this study

*Sequences assembled in the study

S2 -Table of the overall nucleotide frequency and skew throughout the maxicircle genome of various trypanosomatid species.

S3 - Self dottup plot comparative analysis of the entire maxicircle genome (right panel) and divergent region (left panel) of various trypanosomatid species

S4 - Analysis of repeated sequences in the maxicircle divergent region

S5 - Determination of optimal feature/k-mer length (k) for 46 trypanosomatid species.

(A) Graph shows the determination of the minimum feature/k-mer length for DNA. The optimal lower-feature length (k) is considered the point where the most features can be found in most genomes (i.e. peak of curve). (B) Graph shows the determination of the maximum feature/k-mer length for DNA. The optimal upper-feature length (k) is considered the point where the genome curves start having zero REF or begins falling to <10% of their REF maximum values [24].

S1 – Table of all trypanosomatid species used in this study.

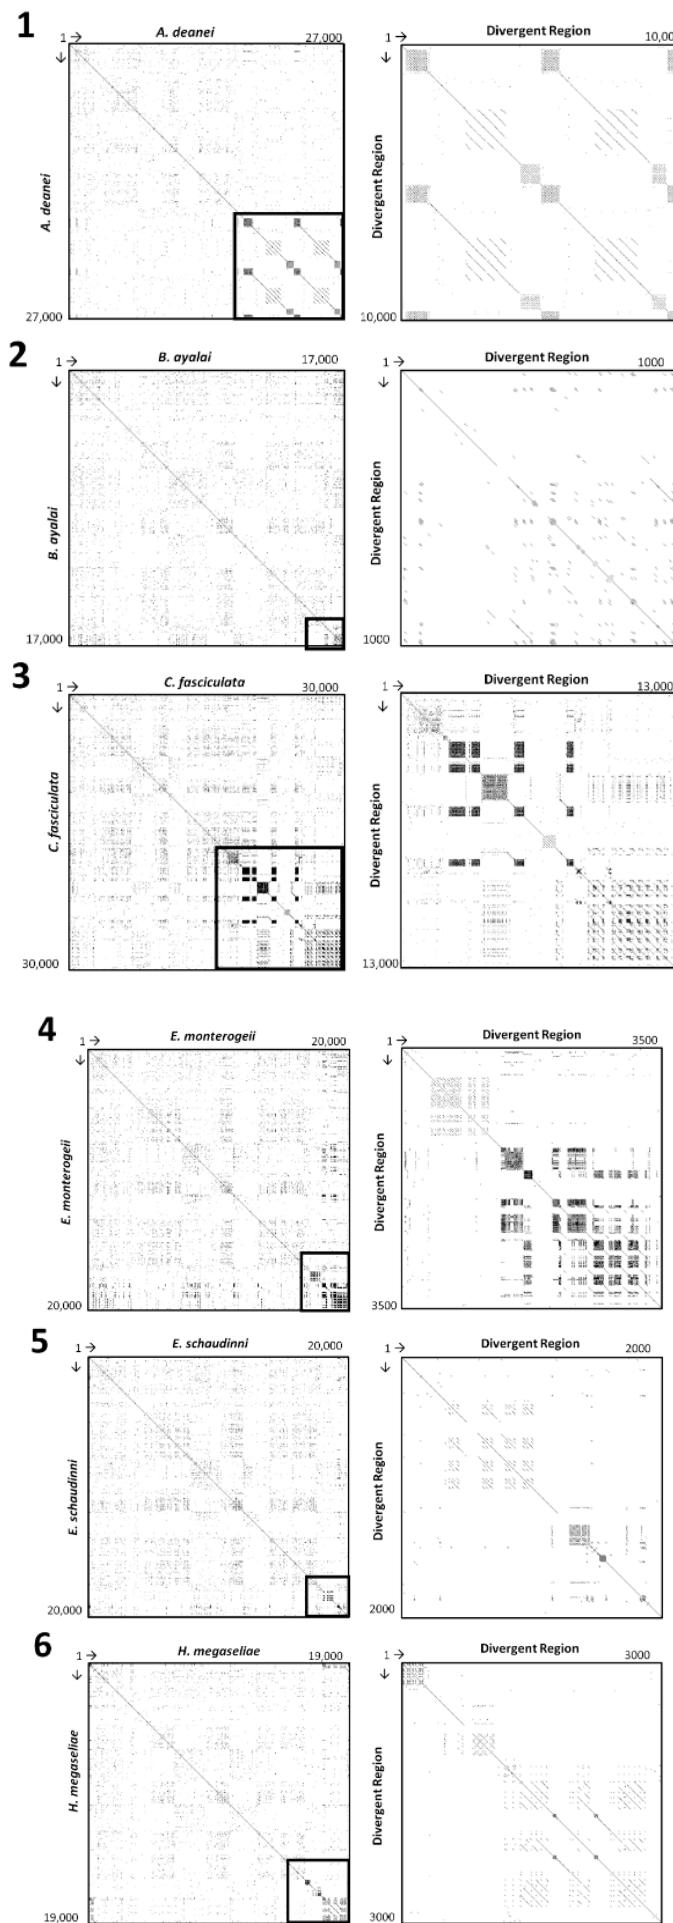

Species	Genbank/TriTryp	Species	Genbank/TriTryp
