Screening of the filarial nematodes in ant cricket

To rule out the possibility that the detected *Wolbachia* were derived from parasitic filarial nematodes frequently found inside insects [1], we screened for the presence of filarial nematodes using two polymerase chain reaction (PCR) assays involving two nematode universal primer pairs (5.8s-1/KK-28S-22 [2]; SSU18/SSU26R [3]) that amplify the ITS2 region and 18S RNA gene of nematodes, respectively. A PCR mixture was set up in a reaction volume of 25 µl using Takara EmeraldAmp Max PCR Master Mix (Takara, Japan). PCRs were carried out following the procedures described in main text with slight modifications (56 °C as annealing temperature for ITS2 region; 50 °C for 18S RNA gene). We detected no signs of filarial nematodes in any ant cricket samples in this study.

Wolbachia strain verification in *Myrmecophilus americanus* using Illumina sequence data

The *Wolbachia* MLST gene sequences of *M. americanus* were characterized using genome sequences generated by the high-throughput sequencing method. DNA libraries were prepared from genomic DNA of three *M. americanus* collected from Taiwan using the Truseq Nano DNA HT Sample Prep Kit (Illumina, USA) for 350 bp inserts, and each DNA library was sequenced on the Illumina Hiseq 4000 platform by Genomics BioSci and Tech Corp (Taipei, Taiwan), generating 150 bp paired-end reads. Trimmomatic 0.36 [4] was employed to remove adaptor sequences and trim bases with quality lower than 20 (QV20). We detected four types of *Wolbachia* infection in *M. americanus* by sequencing *wsp* gene from a number of clones. One type of *wsp* sequence, namely *wMame2*, differed from all known *Wolbachia* strains. Three of the four types of *wsp* sequence in *M. americanus* were identical to *Wolbachia* strains *wMsp4* and *wMsp5* from ant crickets, and *wLonF* from longhorn crazy ant, *Paratrechina longicornis* (Fig. 1b, Table 2), respectively. To confirm *Wolbachia* strain identity detected in *M. americanus*, we mapped the sequencing reads of *M. americanus* onto the MLST reference sequences from *wMsp4*, *wMsp5* and *wLonF* using bowtie2 v2.3.3 [5] in the local alignment

mode. The bowtie outputs (BAM files) were deposited in Zendo (doi: 10.5281/zenodo.3653448). *Wolbachia* type *wMame2* was excluded from the analysis because reference sequences of *wMame2*-like *Wolbachia* were not available. Integrative Genomics Viewer (IGV version 2.5.3) was used to visualize the mapping [6]. Multiple reads matched with the entire reference sequences perfectly, with one exception: the reference sequence *fbpA* of *wLonF* was only partially aligned (Figure S1E). Therefore, a primer pair, [FbpwLonF-F (5'-GCTCCAATTCTTGCATTCAA-3') and FbpwLonF-R (5'-CCAATTCGTTGGATAACGAT-3')], was designed to amplify the *fbpA* sequence unique to *wLonF* in *M. americanus* samples. The PCR conditions included an initial denaturation step at 95°C (3 min) followed by 35 cycles of 94°C (30 s), 55°C (30 s), 72°C (1 min) and a final extension phase at 72°C (7 min). The PCR amplicons were purified and sequenced. A total of five *M. americanus* infected with *wMame1* were sequenced in both directions by using the specific primers. The results indicated that the sequences obtained from *M. americanus* were identical to the *fbpA* sequence of *wLonF*. Summing up, we conclude that the *Wolbachia* in *M. americanus* were identical to *wMsp4*, *wMsp5* and *wLonF* at both *wsp* and MLST loci, assuming no sequence recombination among strains.

Determination of *Wolbachia* MLST alleles in *Camponotus* sp. triple infection samples

Results of *wsp* sequencing indicated that the ant samples from *Camponotus* sp. colony were infected with three types of *Wolbachia*, *wCamA1*, *wCamA2* and *wCamA3*. The *wsp* sequences of *wCamA1*, and *wCamA3* were identical to *wMsp6* and *wMsp4*, while *wCamA2* was identical to *Wolbachia* strains previously reported from ants *Rhytidoponera metallica* (Strain: Rmet_A; PubMLST id: #122) and *Pheidole* sp. (Phe_A_19-04; PubMLST id: #127). We utilized both nanopore-based sequencing and Sanger sequencing to characterize *Wolbachia* MLST allele profiles for these three *Wolbachia* strains. The PCR amplicons of *Wolbachia* MLST genes were purified by using the Gel/PCR Extraction Kit (Nippon Gene, Japan) and 1 mg of purified DNA (200 ng for each gene) was used to construct nanopore sequencing library using the Oxford Nanopore Technologies SQK-LSK109 kit following the manufacturer's instructions. Sequencing was performed on an Oxford Nanopore Technologies (Oxford, UK) MinION (MIN-101B) with FLO-MINSP6 flow cell. The sequencing run was terminated after 2 h and generated 449,808 reads. Reads with an average Q-score lower than 10 or of a length

smaller than 360 bp were filtered out through NanoFilt v 2.6.0 [7], resulting in 24,674 remaining sequences. We mapped all the filtered sequencing reads onto the MLST reference sequences from *wMsp6* using bowtie2 v2.3.3 [5] in the local alignment mode. The bowtie outputs (BAM files) were deposited in Zendo (doi: 10.5281/zenodo.3653448). Integrative Genomics Viewer (IGV version 2.5.3) was used to visualize the mapping results and recover MLST haplotypes with SNPs that are identified in the mapping results [6]. All the SNPs detected by mapping were validated by bi-directional Sanger sequencing of the five MLST loci. The mapping result indicated that the five MLST loci were represented by three alleles each, and allele types were identical or nearly identical to MLST alleles found in one of the following *wMsp4*, *wMsp6* or Phe_A_19-04 (1 bp difference from *wMsp4* at *fbpA*; 1 bp difference from Phe_A_19-04 at *gatB* and *fbpA*). The MLST allele profile of *wCamA1*, *wCamA2* and *wCamA3* was constructed based on the strain information of *wMsp4*, *wMsp6* or Phe_A_19-04, assuming no sequence recombination among strains.

Reconstruction of *wsp* gene tree

We estimated the *wsp* gene tree using a maximum-likelihood (ML) method with RAxML Blackbox web-servers [8]. All available *Wolbachia* sequences from orthopteran insects and ants were downloaded from GenBank and *Wolbachia* PubMLST database and included in the analysis after excluding redundant sequences. Alignment of *wsp* dataset was constructed on the GUIDANCE2 Server [9] based on codons using the MAFFT algorithm [10], and ambiguous alignments with the confidence score below 0.7 were excluded (426 bp remained). The nucleotide substitution models and best partitioning schemes were estimated with PartitionFinder version 2.1.1 [11] using the Akaike information criterion and a heuristic search algorithm. The best partitioning scheme selected by PartitionFinder for *wsp* gene were data partitioned by codon positions under the GTR+I+G model of rate substitution.

Table S1 Behavioral differences between non-integrated and integrated ant crickets based on Ooi (2019) [12]

	Non-integrated ant crickets	Integrated ant crickets
Preferred location in ant nest	Peripheral	Within nest
Feeding	Feed on food without the aid of host ants	Feed via mouth-to-mouth trophallaxis by ant worker
Trophallaxis	Unable to initiate the trophallaxis with host ants, but sometimes interrupt trophallaxis by two ant workers to take the food being transferred	Able to initiate trophallaxis with host ants
Consume ant brood	Often	Rare
Interaction with ant host	Avoid contact with ant and escape rapidly by running and jumping	Come into contact with an ant worker and groom it, licking the body of the ant
Level of host dependence	Medium to low, able to survive more than 2 months without host ants	High, unable to survive more than 1 month without host ants

Table S2 Recorded host ants of the tested ant cricket species

Recorded hosts	List of host ant species	References
<i>Myrmecophilus albicinctus</i>	<i>Anoplolepis gracilipes</i> (major), <i>Pheidole</i> sp. (one record)	[13, 14]
<i>Myrmecophilus americanus</i>	<i>Paratrechina longicornis</i> (major), <i>Camponotus</i> sp. (one record)	[15]
<i>Myrmecophilus antilucanus</i>	<i>Anoplolepis gracilipes</i>	[16]
<i>Myrmecophilus dubius</i>	<i>Anoplolepis gracilipes</i> (major)	[16, 17]
<i>Myrmecophilus hebardi</i>	<i>Paratrechina longicornis</i> (major), <i>Camponotus</i> sp. (one record)	[16, 18, 19]
<i>Myrmecophilus quadrispina</i>	<i>Anoplolepis gracilipes</i> , <i>Paratrechina longicornis</i> , <i>Solenopsis invicta</i> , <i>Solenopsis geminata</i> , <i>Pheidole megacephala</i> , <i>Carebara diversus</i> , <i>Polyrhachis dives</i> , <i>Nylanderia amia</i> , <i>Camponotus kaguya</i> , <i>Pheidole noda</i> , <i>Pheidole parva</i> , <i>Pheidole</i> sp., <i>Diacamma</i> sp., <i>Brachyponera chinensis</i>	[16, 13, 20, 21]

Figure legends

Figure S1. Alignment of Illumina paired-end sequence reads to the reference MLST sequences (A) *hcpA*, (B) *ftsZ*, (C) *gatB*, (D) *coxA* and (E) *fbpA* of *wLonF* (top), *wMsp4* (middle), and *wMsp5* (bottom). Note only those reads perfectly matching the reference sequences were shown.

Figure S2 Genealogical relationships of *Wolbachia* strains. (a) Maximum Likelihood (ML) tree and (b) subtrees for *Wolbachia* strains based on *wsp* gene. Black circles indicate sequences data generated in this study. Strains are represented by the infected arthropod host species with which they are associated. *Wolbachia* from ant crickets, ants, and orthoptera are colored yellow, blue, and pink respectively.
