## Supplemental Note

### Recombination breakpoints

Recombination is a phenomenon that occurs in the genomes of many organisms through the exchange or transfer of genomic fragments demarcated by recombination breakpoints. In the evolution of fungi, recombination is documented as one of the major forces driving diversity and adaptation [1, 2] subsequently resulting in the creation of mosaic sequences where the evolutionary history at each site may be different. With recombination, nucleotide sites in a sequence do not evolve along a single tree, but instead along a set of correlated trees [3]. Violating this tree-like assumption of evolution can lead to serious consequences when performing positive selection analysis [4]. Thus, the evolution of homologous recombinant sequences must be modelled by several phylogenies, one for each nonrecombinant fragment in the alignment [5]. The widely used likelihood methods for quantifying selection pressure on codon alignments [6] may suffer from high rates of false positives when the sequences being analyzed have undergone recombination [4, 7]. Therefore, we analyze the presence of recombination breakpoints in SCOs clusters. We used the Genetic Algorithm Recombination Detection (GARD) tool that implements the likelihood-based model selection procedure and uses the genetic algorithm to screen MSA for recombination breakpoints and quantifies the strength of support for their location [5, 8]. We implemented the Shimodaira-Hasegawa (SH) test to reject the potentially recombinant areas which might be due to substitution rate variation and not the recombination, since only a subset of recombination breakpoints convey any selective advantage, and the majority may be selectively neutral with limited biological significance [9]. We found that significant recombination events occurred in 879 single copy ortholog clusters (Additional file 2: Table S15).

We further conducted GO over-representation analysis of proteins that possibly experienced recombination. In the BP terms, the top two enriched GO terms were response to stress and purine ribonucleotide biosynthetic process, the MF terms were structural constituents of ribosome and phospholipase D (PLD) activity, and the CC terms were related to organelle and mitochondria. Here we have highlighted the role of proteins under BP and MF categories. Detailed alignments are listed in (Additional file 2: Table S5) including the low-level over-representation of recombination breakpoints. Studies have shown the positive correlation between stress and recombination activity [10, 11]. In *Drosophila melanogaster*, it has also been suggested that stress-induced recombination might be a mechanism of evolvability as

certain types of stress, for instance heat shock stress, have the capacity to stimulate evolutionary changes [12]. Several stress-related proteins of *A. fumigatus* and *A. nidulans* have previously shown to be involved in recombination [13-16]. Highly significant over-representation of the GO category, cellular response to stress (GO:0033554, FDR 1.44E-03), suggest recombination might be a general stress response in aspergilli. The increased genetic flexibility by recombination might facilitate evolutionary adaptation of fungi to stressful environments.

Purines are essential nutrients required for functions as diverse as signal transduction, energy metabolism, and DNA synthesis. They are also required by the pathogenic fungi to enable growth and dissemination in the host. Due to varying concentrations of purines in their environmental niches and the host, most of the fungal pathogens can degrade, salvage, and synthesize de novo purines through several conserved enzymatic steps [17]. The purine nucleotide biosynthesis pathway is conserved between yeast and humans and is critically important for the normal functioning of cells. Additionally, dysregulation of this pathway can result in cytotoxicity [18]. High-frequency genetic variation in two purine biosynthesis genes influences survival of bacterial pathogen *Campylobacter jejuni* under stress and promotes its success as a pathogen [19]. We found that the over-representation of the GO category, purine ribonucleotide biosynthetic process (GO:0009152, FDR 1.82E-03), suggests the recombination in these genes could be the adaptive strategy of aspergilli.

Highly transcribed genes, such as the ribosomal genes, are more susceptible to recombination [20]. In agreement with this, we also found over-representation of several ribosome-related GO terms such as ribosome biogenesis (GO:0042254, FDR 2.54E-02), ribosome (GO:0005840, FDR 2.83E-02) and structural constituent of ribosome (GO:0003735, 2.77E-02) (Additional file 1: Table S5). Other than their primary functions in protein translation, ribosomal proteins (RPs) are found to have extra-ribosomal functions that are related to regulation of apoptosis, cell cycle arrest, cell proliferation, cell migration and invasion, and DNA damage repair [21, 22]. In response to DNA damage, RPs can help to maintain genomic stability by regulating the activity of the relevant key transcription factors [23]. To support the hyphal growth, the number of ribosomes in an ungerminated spore is insufficient, therefore, ribosome production is a major synthetic process during the early minutes of germination in filamentous fungi [24]. This process results in a 10-fold increase in the number of ribosomes actively engaged in translation within the first few minutes [25-27]. The degree of transcription involved enhances the opportunity for recombination. Thus, the over-representation of ribosome related GO terms in

recombination breakpoints containing proteins is not surprising as there the transcription is strong.

Phospholipases are ubiquitous enzymes that participate in multiple cellular functions such as vesicular trafficking, receptor signaling and signal transduction. Phospholipase D (PLD) catalyzes the hydrolysis of phosphatidylcholine into phosphatidic acid (PA). The PLD encoding gene modulates the internalization of this pathogen into epithelial cells and represents a virulence factor of *A. fumigatus* in IA under immunosuppression by corticosteroids [28]. PLD activity and its presence in the nucleus are necessary for signaling and the completion of meiosis [29, 30]. Therefore, over-representation of phospholipase D activity is not surprising.

### **Positive selection in genes classified under KOG functional categories**

#### ***Metabolism***

Inhaled resting conidia in immunocompromised individuals become metabolically active within 30 min of ingestion. Cellular energy is essential for the multiplication and stress tolerance. *Aspergillus* species have an remarkable capacity for energy generation, and high efficiency to acquire and utilize a wide range of resources and can store considerable quantities of nutrients within the cell; all traits which contribute to their energy-generating capacity and competitive ability [31]. *A. fumigatus* and some other aspergilli possess and express multiple genes for the enzymes that regulate pathways which allow fungi to adapt their primary carbon metabolism requirement in the niche they inhabit and confer a selective advantage [32]. Also, the possibilities of positive selection signatures in other metabolic genes can be expected. Our scan revealed that several genes involved in metabolic processes evolve under positive selection pressure. This also includes eleven differentially expressed metabolic genes during conidial/hyphae growth. Positive selection pressure was observed in five genes (Afua\_2g15730, Afua\_2g17080, Afua\_6g04500, Afua\_1g07220 and Afua\_3g08480) in KOG class carbohydrate transport and metabolism. Interestingly, a highly significant positive selection signal (Benjamini-Yekutieli, q-value 0) was observed in a key regulatory glycolytic enzyme 6-phosphofructo-2-kinase 1 coding gene (Afua\_1g07220) which catalyzes the conversion of fructose 6-phosphate and ATP to fructose 1,6-bisphosphate and ADP. In response to the cells energy requirements, this enzyme can increase or decrease the rate of glycolysis through allosteric inhibition.

Active fatty acid and lipid metabolism ensure the capability of *A. fumigatus* for using alternative carbon sources in the stressful host environment in infected tissue during invasive

aspergillosis [33, 34]. Additionally, also serve as the energy source for intracellular growth of *A. fumigatus* conidia [35]. Triacylglycerides (TAGs) are a class of neutral lipids that represent the most important primary storage form of energy for eukaryotic cells, which is often synthesized via multiple pathways. Phospholipid:DAG acyltransferase (PDAT) that transfer a fatty acyl moiety from a phospholipid (PL) to diacylglycerol (DAG) to form TAG represents one such acyl-CoA-independent TAG synthesis pathway. This membrane-localized enzyme coding gene Afua\_3g09950 was identified as PSG by our analysis. The artificial microRNA silencing of PDAT suggests that membrane lipid turnover and TAG synthesis mediated by PDAT is essential for vigorous growth of alga *Chlamydomonas reinhardtii* under favorable culture conditions and for membrane lipid degradation with concomitant production of TAG for survival under stress [36]. BlastP based similarity search shows *A. fumigatus* PDAT shares 43% sequence similarity with *C. reinhardtii* PDAT. Further, having similar domains and similar GO annotations of both the proteins indicate their similar functions. Five genes involved in oxidative stress response (Afua\_4g04710, Afua\_3g11330, Afua\_1g10930, Afua\_3g09950 and Afua\_2g11510) were found to be positively selected. We also found the signal of positive selection in acyl-CoA thioesterase II coding gene Afua\_1g15170 which highly downregulates during 16 h of conidia growth. The enzyme is involved in lipid metabolism [37] as mentioned in later in the manuscript however, its role in *A. fumigatus* is not yet characterized. The Afua\_5g08930 *ivdA* gene codes for the isovaleryl-CoA dehydrogenase enzyme, which participates in branched-chain amino acid leucine catabolic process and fatty acid beta-oxidation, (and) was found to be evolved under positive selection. The distant bacterial homolog *Mycobacterium tuberculosis* acyl-CoA dehydrogenase *mbtN*, which shows about 25% sequence identity to *A. fumigatus* Isovaleryl-CoA dehydrogenase and contains similar domain composition and GO annotation, is considered a virulence factor because of its involvement in the production of mycobactins and possibly vital for the iron acquisition within the macrophage [38, 39]. Another mitochondrial enzyme 3-methylcrotonyl-CoA carboxylase subunit alpha coding gene Afua\_5g08910 *mccA*, involved in leucine degradation, was evolved under positive selection. This enzyme showed differential expression during conidia growth [40], oxygen-limitation [41], and host neutrophil interaction [42]. In oxygen-limiting conditions many pathogens are able to use leucine as the sole carbon or nitrogen source through the leucine degradation pathway leading to acetyl-CoA and acetoacetate, an important end-product of energy metabolism [43].

In fact, metabolism cannot proceed without energy, and thus adaptive evolution is expected in genes involved in the energy production and conversion subcategory, if the host encounters

pathogen adaptation. *A. fumigatus* generate energy in vivo during fungal pathogenesis to drive the metabolic pathways required for fungal growth, host tissue invasion, and disease development using different mechanisms [44]. Mitochondrial respiration is active in hypoxia and critical for fungal pathogenesis [45, 46]. Interruption of mitochondrial respiration in *A. fumigatus* significantly impaired growth in normoxia and hypoxia, conidial germination, and displayed attenuated virulence [47]. Positive selection was observed for electron transfer flavoprotein-ubiquinone oxidoreductase (ETF:QO) coding gene Afua\_3g10110, which is critical for linking central metabolism with the respiratory chain [48]. The Afua\_3g08770 *grim-19* gene codes for the component of mitochondrial respiratory chain NADH:ubiquinone oxidoreductase complex (complex I), which catalyzes the first step of electron transfer in the oxidative phosphorylation system (OXPHOS), was positively selected. Elimination of *grim-19* destroys the assembly and electron transfer activity of complex I and influences the other complexes in the mitochondrial respiratory chain [49, 50]. It also influences the Warburg effect, favors cell protection and/or prevent aberrant cell growth, apoptosis and also appears to regulate innate and acquired immune responses in mouse models [50-52]. The subunit of mitochondrial matrix pyruvate dehydrogenase (PDH) complex, E1 component subunit alpha coding gene Afua\_1g06960, was found to be rapidly evolved. The PDH complex catalyzes the overall conversion of pyruvate into acetyl-CoA and CO<sub>2</sub>, and thereby provides the primary link between the glycolytic pathway to the tricarboxylic acid (TCA) cycle. The product of PSG acetate kinase Afua\_3g10750 *ack* gene converts acetyl phosphate to acetate along with the phosphorylation of ADP and is one of the most prominent ATP-generating reactions in anaerobic respiration. Therefore, *ack* is involved in glucose fermentation to acetate. The growth of a bacterial mutant lacking *ack* has been shown to be inhibited by glucose, suggesting that *ack* is involved in excretion of excess carbohydrate [53]. Positive selection of *A. fumigatus* *Ack* may therefore be the pathogens strategy to escape with the host interference during anaerobic respiration.

The amino acid asparagine is required for the synthesis of many important cellular proteins in normal cells. Differential expression of asparagine synthetase Afua\_4g06900 *asn2* has been observed during early developmental stages of *A. fumigatus* conidia [40]. *asn2* and an another asparaginase family protein Afua\_5g11570 showed the signature of positive selection. The positive selection was seen for the gene Afua\_5g11450 which encodes for the regulatory protein of arginine metabolism. Arginine can be used as a nitrogen compound to repress the secretion of the alkaline protease that *A. fumigatus* uses to degrade and destroy the host complement system ability to make fungal hyphae susceptible to phagocytosis [54]. The

biosynthesis of arginine is important for pathogenicity, hyphal growth, and siderophore biosynthesis, which is coordinated by the supply of ornithine that is produced either by mitochondrial glutamate or in the cytosol by hydrolysis of arginine [55].

### **Cellular processes and signaling**

A high number of PSGs annotated are involved in cellular processes and signaling (Additional file 2: Table S8). Majorly involved functional subcategories were signal transduction mechanisms; intracellular trafficking, secretion, and vesicular transport, posttranslational modification, protein turnover, chaperones, and others (Fig. 6). During the conidial growth, like other filamentous fungi, a germ tube apical extension of *A. fumigatus*, a mode of growth that involves the establishment of a stable axis of polarity, followed by the maintenance of growth in the same direction, is regulated by several polarity maintenance genes [56]. The ability to sustain polarization requires a constant stream of new cell wall and plasma membrane material to the hyphal apex [57]. The Centrin-binding protein coding gene Afua\_1g13700 *sfi1*, essential for the initiation of spindle pole body duplication [58] and critical in the cell division cycle, was found to be positively selected. PSG Afua\_3g14340 *mad2* which codes for the evolutionarily conserved central component of the mitotic checkpoint complex, is essential for the spindle assembly checkpoint mechanism [59]. PSG Afua\_2g06110 *arp4* codes for a cytoskeletal protein involved in histone acetylation, histone exchange, and regulation of nucleosome density. In *C. albicans*, a mutant phenotype of *arp4* resulted in a decrease of cell size [60]. Several genes related to vesicles were positively selected (KOG class - 'U', Additional file 2: Table S8). Membrane-enclosed vesicles of the secretory system transport here components. The latter are required for membrane and cell wall biogenesis to the growing tip cell [61]. Besides involvement in growth, vesicles participate in importing nutrients from the host and exporting virulence factors to extracellular space. Differentially expressed PSGs during the conidia growth include the clathrin heavy chain, mitochondrial import receptor subunit Afua\_1g11860 *tom22*, and Rab small monomeric GTPase Afua\_5g12130 *rab7*. The clathrin heavy chain is involved in the formation of coated vesicles and clathrin-dependent endocytosis. *tom22* mediates protein import into the mitochondrial matrix and mitochondrial outer membrane [62]. *rab7* plays a central role in the transport steps connecting late endosomes to upstream and downstream endocytic compartments and possibly to the phagocytic route [63]. The components of the cytoplasmic dynein complex, dynein family protein coding gene Afua\_5g08510 *nudN*, showed the signature of positive selection. The cytoplasmic dynein complex play roles in mitotic regulation and intracellular transport of vesicles and organelles

[64]. Selection pressure was also observed on several genes involved in signal transduction mechanisms (KOG class - 'T', Additional file 2: Table S8). For instance, Afua\_4g04710 *pyp1*, which has an ortholog in *Schizosaccharomyces pombe*, is involved in MAP kinase tyrosine phosphatase activity, negative regulation of G2/M transition of mitotic cell cycle, stress response, and osmo-sensory signaling pathway [65] and was found to be evolved under positive selection. Since *pyp1* is annotated as negative regulator of stress-activated MAPK cascade, it probably can control the functional consequence of MAPK activity in *A. fumigatus*, such as cell wall integrity, fungal morphology, and oxidative stress [66]. Protein phosphatase 2C (Afua\_1g15800) mutants of *A. fumigatus* grow better than wild type in iron excess conditions [67]. Besides serine/threonine phosphatase activity, protein phosphatase 2C orthologs in fungi are involved in diverse functions (reviewed in [68]), including the virulence [69] in human fungal pathogen *Candida albicans*. Another important gene that evolved under adaptive evolution includes Afua\_4g08050 *sac1*, which is required for virulence of *C. albicans* and its mutants. This gene also has induces attenuated filamentous growth and biofilm formation, hypersensitivity to cell wall stresses, and changed content and distribution of chitin [70]. Furthermore, several genes coding for proteins involved in posttranslational modification, protein turnover, and chaperone activity were positively selected (KOG class - 'O', Additional file 1: Table S8). This subcategory also includes Afua\_3g12290 *dim1*, which is an essential gene for the viability of *A. fumigatus* [71]. The ortholog of *dim1* is involved in mRNA splicing, regulation of DNA methylation, mitotic spindle formation, and chromosome segregation [72].

### **Information storage and processing**

In this category 33 PSGs were identified and among them most participate in transcription and related processes (Additional file 1: Table S8). PSG Afua\_3g10240 *not1* codes a scaffold protein which is a critical component of Ccr4-Not complex regulating gene expression, mRNA turnover, translational repression, and transcription [73]. Not protein subunits have been found to repress transcription of promoters without a canonical TATA sequence and among the different components of Ccr4-Not complex, only *not1* is known to be essential for yeast viability [73] and growth [74]. The complex in general is regulatory and it regulates cellular processes upon sensing the nutrient levels and other signals and it is thought to be required to keep cells in the appropriate state and to respond to extracellular signals [75]. The ortholog of Afua\_2g05020 *dopA* codes a regulatory protein which has been discovered to play a role in several processes, including transport from Golgi to endosome, hyphal growth, cell morphogenesis, spatiotemporal organization of multicellular structures, conidium formation

and endoplasmic reticulum organization and viability [76]. PSG Afua\_5g04200 *rpc82* codes for the RNA polymerase C subunit protein, which has been identified to be essential for yeast cell viability [77]. Additionally, this protein was also annotated with the GO term ‘pathogenesis’ (GO:0009405). The ortholog of C6 transcription factor (Afua\_6g11110) regulates cell wall architecture, hyphal morphogenesis, virulence, and drug sensitivity in *C. albicans* [78]. In yeast, this protein participates in the regulation of glucose metabolism and fermentation [79]. Afua\_5g12190 *taf30* codes a hub protein in the *A. fumigatus* interactome [80], which interacts with many complexes, such as general transcription factors that make up the RNA polymerase II preinitiation complex, chromatin remodeling complexes, and the histone modification enzymes. The highly conserved domain “Yeats” containing the *taf30* ortholog of yeast was found to affect the cell growth in a negative way, in which cells grow better than wild-type in stress conditions when this domain is absent [81]. Some genes involved in the initiation of transcription for instance, Afua\_8g04950 *tsm1* and Afua\_8g04350, were also found to be evolved under positive selection. Moreover, positive selected genes are involved in DNA replication, recombination, and repair. For instance, gene Afua\_2g10140 *mcm7* that codes a part of MCM complex, which plays a role in initiation and regulation of DNA replication, was found to be positively selected. Higher amounts of evolutionarily conserved MCM proteins has been observed in proliferating cells [82]. Afua\_5g03320 *ssl2* provides DNA helicase functions and participates in transcription and DNA repair. Furthermore, the ortholog of *ssl2* leads to growth defects when mutated in yeast [83] and is also essential for cell viability [84]. Under the subcategory RNA processing and modification, Afua\_1g14310 *pan3*, the required subunit of the PAN enzyme the function of which is to shorten mRNA poly(A) tails [85] and regulate the activity of post replication repair complexes [86], was identified.

## Supplementary figures

**Figure S1: Proteins-protein interactions (PPIs) map.** PPIs between *A. fumigatus* proteins coded by positively selected genes (PSGs) and human proteins. Orange - *A. fumigatus* proteins and blue - human proteins.

**Figure S2: Gene Ontology (GO) overrepresentation analysis.** Biological process (GO) significantly overrepresented in human proteins targeted by *A. fumigatus* virulence related proteins coded by multi-copy category positively selected genes (PSGs).

**Figure S3: *A. fumigatus* and *A. fischeri* genome synteny map.** Image was generated using the Mauve genome alignment tool. Upper and lower lines of the genomes correspond to *A. fumigatus* and *A. fischeri* respectively. Red vertical bars indicate concatenated chromosomal boundaries. Color-coded syntenic blocks indicate conserved segments (LCBs; Locally Collinear Blocks) identified by Mauve (minimum LCB weight = 999). Plots of sequence similarity are shown within each syntenic block. Regions with no color indicate no detectable homology between the two genomes with the settings used in Mauve. Unmatched regions (white area) within an LCBs indicate the presence of strain-specific sequence. The connecting lines between blocks indicate the location of each block in two genomes. Homologous regions with possible rearrangements are shown in first row.
