

**Table S1.** Result of the Principal Component Analysis (PCA) and the two uncorrelated factors obtained.

| Variable                                | PC1- closed habitats | PC2-watercourse habitats |
|---|----------------------|--------------------------|
| Herbaceous grassland                    | -0.856               | -0.507                   |
| Bare land                               | 0.259                | -0.098                   |
| Watercourse vegetation                  | -0.096               | 0.991                    |
| Woodland, dense and low-clear shrubland | 0.866                | -0.362                   |
| Standard deviation                      | 1.56                 | 1.38                     |
| Explained variance                      | 38.96                | 34.48                    |
| Cumulative variance                     | 38.96                | 73.44                    |

**Table S2.** Summary of the stepwise model selection procedure, based on the corrected Akaike's information criterion (cAIC), used to explain the serological status against HEV. Full model comprises the age class, sex, straight-line distance to the nearest: ecotone (DE), water point (DWAT), small human settlements (DHS), the marshland (DMARSH), stagnant water source (DSW), and the Guadalquivir river (DRIVER), rainfall (rainfall) and temperature (temperature) of the previous sampling period, cover of closed habitats (closed\_ha), coverage of watercourse habitats (water\_ha), annual density of fallow deer (FD\_den) and cattle (cattle\_den), relative abundance of red deer (RD\_KAI) and wild boar (WB\_KAI), intra-specific seroprevalence of HEV (seroprev\_intrasp), and some interaction among them (\*). In bold type is shown the variable which was remove between steps.
