**Abstract:** D-Tagatose, a functional sweetener, is converted from D-galactose by L-arabinose isomerase, which catalyzes the conversion of L-arabinose to L-ribulose. In this study, the *araA* gene encoding L-arabinose isomerase from *Klebsiella pneumoniae* was cloned and expressed in *Escherichia coli*, and the expressed enzyme was purified and characterized. The purified L-arabinose isomerase, a soluble protein with 11.6-fold purification and a 22% final yield, displayed a specific activity of 1.8 U/mg for D-galactose and existed as a homohexamer of 336 kDa. The enzyme exhibited maximum activity at pH 8.0 and 40 °C in the presence of Mn<sup>2+</sup> and relative activity for pentoses and hexoses in the order L-arabinose > D-galactose > L-ribulose > D-xylulose > D-xylose > D-tagatose > D-glucose. The thermal stability of recombinant *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae* was higher than that of the enzyme. Thus, the reaction conditions of the recombinant cells were optimized to pH 8.0, 50 °C, and 4 g/L cell concentration using 100 g/L D-galactose with 1 mM Mn<sup>2+</sup>. Under these conditions, 33.5 g/L D-tagatose was produced from D-galactose with 33.5% molar yield and 67 g/L/h productivity. Our findings will help produce D-tagatose using whole-cell reactions, extending its industrial application.

**Keywords:** *Klebsiella pneumoniae*; L-arabinose isomerase; D-tagatose; D-galactose; recombinant *Escherichia coli*

## 1. Introduction

D-Tagatose, a ketohexose monosaccharide contained in dairy products in small amounts, is an isomer of D-galactose [1,2]. D-Tagatose tastes similar to sucrose (92% sweetness); both sugars lack laxative and cooling effects and are involved in browning reactions [3]. However, D-tagatose possesses numerous health benefits, such as preventing weight gain, improving fetal development, and alleviating symptoms of type 2 diabetes, anemia, and hemophilia [4,5]. Moreover, it is known as a low-calorie and tooth-friendly sweetener, unlike sucrose [6]. Therefore, D-tagatose has attracted significant attention in the fields of foods, beverages, health foods, and dietary supplements [2,7].

D-Tagatose can be chemically synthesized from D-galactose using a calcium catalyst; however, it is undesirable due to disadvantages such as complicated purification steps and the formation of chemical waste and byproducts [8]. Thus, the biological production of D-tagatose from D-galactose using L-arabinose isomerase has been intensively studied. L-Arabinose isomerase, an enzyme catalyzing the conversion of L-arabinose to L-ribulose,

can catalyze the conversion of D-galactose to D-tagatose because of its broad substrate specificity toward similarly configured substrates [9]. To date, D-galactose has been converted to D-tagatose using L-arabinose isomerases from various microorganisms, including *Acidothermus cellulolyticus* [10], *Alicyclobacillus acidocaldarius* [11], *Arthrobacter* sp. [12], *Anoxybacillus flavithermus* [13], *Bacillus coagulans* [14], *Bacillus halodurans* [15], *Bacillus licheniformis* [16], *Bacillus stearothermophilus* [17], *Bacillus subtilis* [18], *Bacillus thermoglucosidasius* [19], *Bifidobacterium longum* [20], *Escherichia coli* [21], *Geobacillus kaustophilus* [22], *Geobacillus stearothermophilus* [23], *Geobacillus thermodenitrificans* [24], *Lactobacillus fermentum* [25], *Lactobacillus plantarum* [26], *Lactobacillus sakei* [27], *Pediococcus pentosaceus* [28], *Shewanella* sp. [29], *Thermoanaerobacter mathranii* [30], *Thermoanaerobacterium saccharolyticum* [31], *Thermotoga maritima* [32], *Thermotoga neapolitana* [33], and *Thermus* sp. [34].

L-arabinose isomerases from thermophilic microorganisms, such as *A. cellulolyticus*, *A. acidocaldarius*, *B. thermoglucosidasius*, *G. kaustophilus*, *G. stearothermophilus*, *G. thermodenitrificans*, *T. mathranii*, *T. saccharolyticum*, *T. maritima*, *T. neapolitana*, and *Thermus* sp., have exhibited higher activity or thermostability than those from mesophilic microorganisms. Therefore, the production of D-tagatose from D-galactose using thermostable L-arabinose isomerase from thermophilic microorganisms has been mainly studied so far. Despite having advantages, thermostable L-arabinose isomerase has limited ability in showing the highest activity in industrial processes, such as fermentation and whole-cell reaction using an intrinsic system of cells, because cells are inactivated at their optimum temperature, which is too high [35–38]. Therefore, additional studies are needed to discover and characterize L-arabinose isomerase from a mesophilic microorganism that has been neglected in recent years. In addition, the production of D-tagatose from D-galactose using whole cells expressing L-arabinose isomerase needs to be evaluated.

In this study, we cloned and expressed L-arabinose isomerase derived from *Klebsiella pneumoniae*, a lactose-fermenting mesophilic bacterium, in *E. coli*. The L-arabinose isomerase was purified and characterized, and *E. coli* cells expressing the enzyme were used for producing D-tagatose from D-galactose.

## 2. Materials and Methods

### 2.1. Microorganism, Plasmid, and Gene Cloning

The DNA template and expression vector for L-arabinose isomerase gene (GenBank accession no. CP000964) cloning and host cells of enzyme expression were *K. pneumoniae* DSM 681 (DSMZ, Braunschweig, Germany), pET-28a (+) vector (Novagen, Darmstadt, Germany), and *E. coli* ER2566 strain (New England Biolabs, Ipswich, MA, USA), respectively. The L-arabinose isomerase gene was amplified from *K. pneumoniae* genomic DNA by polymerase chain reaction (PCR) using the following primers from Bioneer (Daejeon, Korea): Forward (5'-CCCGCTAGCATGACGATTTTGATAACTATGAAGTATG-3') and reverse (5'-GGGAAGCTTTTAGCGTTTGAAGTGTAACTACACTTCATT-3'), introduced into *NheI* and *HindIII* restriction sites (underlined), respectively. The amplified DNA fragments obtained using PCR were purified and inserted into the pET-28a (+) vector digested with the same restriction enzymes. The *E. coli* ER2566 strain was transformed with the ligation mixture using an electroporator (MicroPulser; Bio-Rad Laboratories, Hercules, CA, USA), and the transformed cells were plated on Luria-Bertani (LB) agar containing 20 µg/mL kanamycin. A kanamycin-resistant colony was selected, and plasmid DNA from the transformant was isolated using a plasmid purification kit (Promega, Madison, WI, USA). DNA sequencing was performed at a Macrogen facility (Seoul, Korea).

### 2.2. Culture Conditions and Enzyme Purification

Transformed *E. coli* cells were grown in a 2000 mL flask containing 500 mL of LB medium supplemented with 20 µg/mL of kanamycin at 37 °C with shaking at 200 rpm. When the optical density of the bacterial culture suspension reached 0.5 at 600 nm, 0.1 mM isopropyl-β-D-thiogalactopyranoside was added to the culture medium and incubated at 16 °C for an additional 16 h with shaking at 150 rpm. After cell growth, the induced cells

were harvested and resuspended in 50 mM of phosphate buffer (pH 7.0) containing 300 mM NaCl, 10 mM imidazole, and 1 mg/mL lysozyme. The resuspended cells were disrupted by sonication on ice for 25 min. The unbroken cells and cell debris were removed by centrifugation at  $13,000\times g$  at 4 °C for 20 min. The cell-free supernatant was loaded on a His-Trap HP affinity chromatography column equipped with a fast protein liquid chromatography system (Bio-Rad Laboratories). The bound protein was eluted at 1 mL/min using 50 mM phosphate buffer (pH 7.0) containing 250 mM imidazole at 4 °C. The eluted active fractions were dialyzed against 50 mM phosphate buffer (pH 7.0) without other components at 4 °C for 16 h. The obtained protein was used as purified L-arabinose isomerase.

### 2.3. Sodium Dodecyl Sulfate-Polyacrylamide Gel Electrophoresis (SDS-PAGE) Analysis and Gel Filtration

The subunit molecular mass of L-arabinose isomerase was determined by SDS-PAGE using a prestained ladder (MBI Fermentas, Glen Burnie, MD, USA) as a reference. Coomassie brilliant blue was used to stain protein bands for visualization. The molecular mass of the native L-arabinose isomerase from *K. pneumoniae* was determined by gel filtration chromatography using a Sephacryl S-300 HR 16/60 column (GE Healthcare, Piscataway, NJ, USA). Purified L-arabinose isomerase was applied to the column and eluted at 1 mL/min with 50 mM phosphate buffer (pH 7.0) containing 150 mM NaCl. The column was calibrated using conalbumin (75 kDa), aldolase (158 kDa), ferritin (400 kDa), and thyroglobulin (669 kDa) as reference proteins (GE Healthcare), and the molecular mass of the native enzyme was calculated by comparing its retention time with that of the reference proteins.

### 2.4. Enzyme Assay

The activity of L-arabinose isomerase was determined by measuring D-tagatose converted from D-galactose as a substrate. The reaction was performed with 50 mM D-galactose at 40 °C in 50 mM phosphate buffer (pH 8.0) for 10 min. Then, the enzyme solution was centrifuged, filtered, and used for analyzing the substrate and product. One unit of the activity was defined as the amount of enzyme producing 1  $\mu$ mol of D-tagatose per minute at 40 °C and pH 8.0. To measure the specific activity, the enzyme reactions were performed in 50 mM phosphate buffer (pH 8.0) containing 50 mM sugar and 0.8 U/mL (0.4 mg/mL) of enzyme at 40 °C for 10 min.

### 2.5. Effects of pH, Temperature, and Metal Ions

To examine the effects of pH and temperature on L-arabinose isomerase activity, the pH values were varied from 4.0 to 10.0 using 50 mM citrate buffer (pH 4.0–6.0), phosphate buffer (pH 6.0–8.0), and Tris-HCl buffer (pH 8.0–9.0) at a constant temperature of 35 °C, and temperatures were varied from 30 to 60 °C in 50 mM phosphate buffer at a constant pH of 8.0. The reactions were performed using 50 mM D-galactose and 0.8 U/mL enzymes for 10 min. The effect of temperature on the stability of the enzyme and *E. coli* cells expressing the enzyme was monitored as a function of incubation time by incubating the reaction solutions of the enzyme and cells at 40 °C and 50 °C, respectively, in 50 mM phosphate buffer (pH 8.0) containing 50 mM and 20 g/L D-galactose.

The purified enzyme was treated with 10 mM ethylenediaminetetraacetic acid (EDTA) and dialyzed against 50 mM phosphate buffer (pH 8.0) to prepare an EDTA-treated enzyme. To investigate the effect of metal ions on L-arabinose isomerase activity, the reactions were performed at 40 °C in 50 mM phosphate buffer (pH 8.0) containing 50 mM D-galactose, 0.8 U/mL EDTA-treated enzymes, and 1 mM of various metal ions such as Ba<sup>2+</sup>, Ca<sup>2+</sup>, Co<sup>2+</sup>, Cu<sup>2+</sup>, Fe<sup>2+</sup>, Mg<sup>2+</sup>, and Mn<sup>2+</sup>.

### 2.6. Optimization of Reaction Conditions Using *E. coli* Cells Expressing L-Arabinose Isomerase

Unless otherwise stated, the reaction using transformed *E. coli* cells expressing L-arabinose isomerase was performed with 20 g/L of D-galactose and 1 g/L of cell at 50 °C in 50 mM phosphate buffer (pH 8.0) for 10 min. The effects of pH and temperature

were investigated to optimize the production of D-tagatose from D-galactose using *E. coli* cells expressing L-arabinose isomerase as in the above enzymatic methods. To determine the optimal concentration of *E. coli* cells expressing L-arabinose isomerase, the reactions were performed by varying *E. coli* cell concentration from 0.5 to 5 g/L supplemented with 100 g/L D-galactose. The reactions were performed in 50 mM phosphate buffer (pH 8.0) at 50 °C for 30 min. The production of D-tagatose was performed in 50 mM phosphate buffer (pH 8.0) containing 4 g/L cells and 100 g/L D-galactose at 50 °C for 45 min.

### 2.7. Analytical Methods

The concentrations of protein and cells were determined using the Bradford method with bovine serum albumin as the protein standard and a calibration curve derived from the correlation between dry cell weight and optical density at 600 nm. The concentrations of monosaccharides were determined using a Bio-LC system (Dionex ICS-3000, Sunnyvale, CA, USA) equipped with an electrochemical detector and a CarboPac PA1 column, which was eluted at 30 °C with 200 mM sodium hydroxide at a flow rate of 1 mL/min.

## 3. Results and Discussion

### 3.1. Gene Cloning, Purification, and Molecular Mass Determination of L-Arabinose Isomerase from *K. pneumoniae*

The 1503 bp of *araA* gene from *K. pneumoniae* DSM 681 with the same sequence in GenBank (Accession No., ABR75521) was cloned and expressed in *E. coli* ER2566. The amino acid sequence of the expressed enzyme showed 91.4%, 59.5%, 59.4%, 59.2%, 52.0%, and 49.0% identities with those of L-arabinose isomerase from *E. coli* (AAA23463) [39], *A. acidocaldarius* (AAY68209) [11], *G. kaustophilus* (BAD76189) [22], *G. stearothermophilus* (AAD45718) [40], *B. subtilis* (CAA61585) [18], and *Arthrobacter* sp. (ABK01625) [12], respectively.

L-Arabinose isomerase from *K. pneumoniae* was purified using His-Trap affinity chromatography into a soluble protein with an 11.6-fold purification, a final yield of 22%, and a specific activity of 1.8 U/mg for D-galactose. The molecular mass of the purified enzyme was approximately 56 kDa on SDS-PAGE (Figure 1a), which was consistent with the calculated value of 57,131 Da based on 493 amino acids combined with six histidine residues. The native enzyme was determined to be a homohexamer with a molecular mass of 336 kDa by gel filtration chromatography (Figure 1b). L-Arabinose isomerases from *E. coli* [39], *G. kaustophilus* [22], *L. plantarum* [26], and *L. fermentum* [41] with 91.4%, 59.4%, 43.6%, and 42.0% sequence identities to L-arabinose isomerase from *K. pneumoniae*, respectively, were hexamers. In contrast, L-arabinose isomerases from *B. licheniformis* [16] and *B. subtilis* [18] with 48.0% and 52.0% sequence identities, respectively, were dimers, and L-arabinose isomerases from *A. acidocaldarius* [11] and *E. faecium* [42] with 59.5% and 47.4% sequence identities, respectively, were tetramers. These results indicate that the level of sequence identity within L-arabinose isomerases does not correlate with determining the association form.

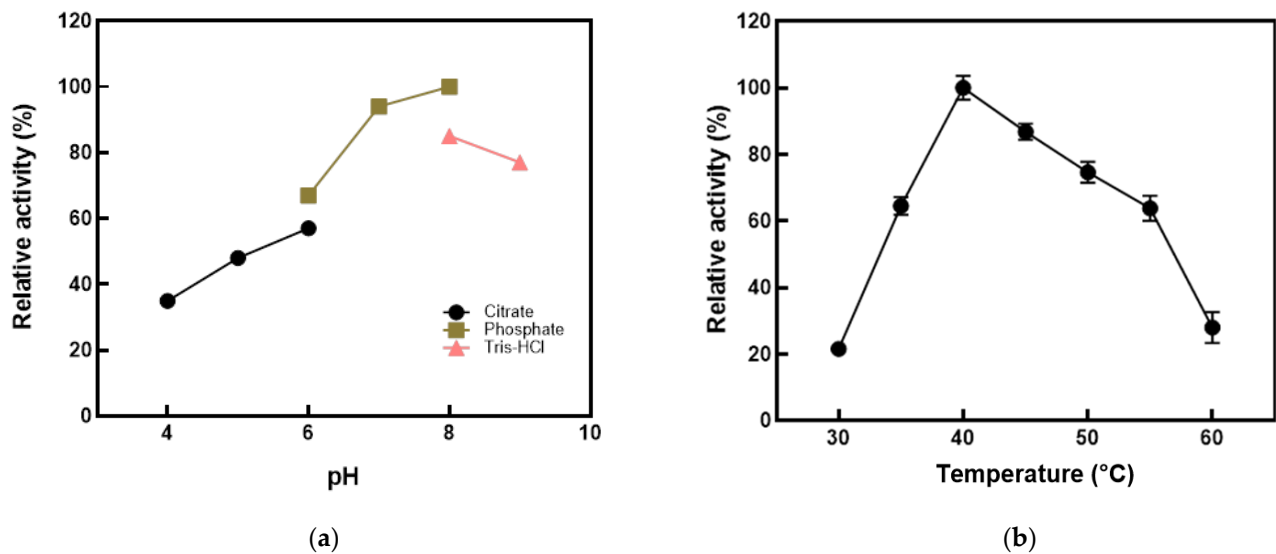

**Figure 1.** SDS-PAGE and gel filtration analyses of L-arabinose isomerase from *K. pneumoniae*. (a) SDS-PAGE of L-arabinose isomerase from *K. pneumoniae*. M, molecular weight size marker proteins; lane 1, pellet; lane 2, crude enzyme extract; and lane 3, purified L-arabinose isomerase from *K. pneumoniae*. (b) Gel filtration chromatography of L-arabinose isomerase from *K. pneumoniae*. The solution of purified L-arabinose isomerase from *K. pneumoniae* (filled square) was applied to a Sephacryl column. The column was calibrated using the reference proteins (empty circle) conalbumin, aldolase, ferritin, and thyroglobulin, corresponding to 75, 158, 400, and 669 kDa, respectively.

### 3.2. Effects of Environmental Factors on the Activity of L-Arabinose Isomerase from *K. pneumoniae*

The effects of pH and temperature on L-arabinose isomerase activity were investigated using varying pH (4.0–9.0) at a constant temperature of 35 °C and varying temperatures (30–60 °C) at a constant pH value of 8.0, respectively. The maximum activity was observed at pH 8.0 and 40 °C (Figure 2). The thermal stability of L-arabinose isomerase from *K. pneumoniae* was evaluated by measuring the residual activity after incubating for 1, 2, 3, 4, and 5 h at 40 °C (Figure 3). The enzyme activity decreased as the time increased. The activity decreased to less than 50% of the initial activity between 3 and 4 h and dropped to less than 20% at 5 h. L-Arabinose isomerase from *K. pneumoniae* showed lower thermostability than other mesophilic L-arabinose isomerases from *B. thermoglucosidasius* [19] and *L. sakei* [27], which displayed residual activities of 80% and 95% for 2 h at 40 °C, respectively, and than from *B. longum* [20], which had a half-life of 52 h at 45 °C. However, the activity of the recombinant *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae* was more than 60% after incubation for 5 h at 50 °C (Figure 3), which indicated that the recombinant cells were more stable in producing D-tagatose from D-galactose than the enzyme.

The effects of metal ions on L-arabinose isomerase activity were evaluated at a concentration of 1 mM (Table 1).  $Mg^{2+}$  and  $Mn^{2+}$  enhanced the activity by 15% and 28%, respectively, and  $Ca^{2+}$  and  $Co^{2+}$  showed similar activity to the negative control (not treated with EDTA), whereas  $Ba^{2+}$ ,  $Cu^{2+}$ , and  $Fe^{2+}$  inhibited D-galactose isomerization. Enzyme activity was the highest when  $Mn^{2+}$  was used, similar to most enzymes, including L-arabinose isomerases from *T. neapolitana* [33], *T. maritima* [43], *T. saccharolyticum* [31], *T. mathranii* [44], *L. fermentum* [25], *L. sakei* [27], and *G. thermodenitrificans* [24].

**Figure 2.** Effects of pH and temperature on the activity of L-arabinose isomerase from *K. pneumoniae*. (a) Effect of pH. The reactions were performed in 50 mM citrate (pH 4.0–6.0), phosphate (pH 6.0–8.0), and Tris-HCl (pH 8.0–9.0) buffers containing 50 mM D-galactose and 0.8 U/mL enzyme at 35 °C for 10 min. (b) Effect of temperature. The reactions were performed in 50 mM phosphate buffer (pH 8.0) containing 50 mM D-galactose and 0.8 U/mL enzyme at different temperatures, ranging from 30 °C to 60 °C for 10 min. Data represent the mean of values from three experiments, and error bars represent standard deviation.

**Figure 3.** Thermal inactivation of L-arabinose isomerase from *K. pneumoniae* (closed square) and *E. coli* cells expressing the enzyme (closed circle). L-Arabinose isomerase or *E. coli* cells were incubated at 40 °C or 50 °C, respectively, withdrawn at each time point, and assayed in 50 mM phosphate buffer (pH 8.0) containing 0.8 U/mL enzyme or 1 g/L cells and 50 mM or 20 g/L D-galactose at 40 °C or 50 °C, respectively, for 10 min. Data represent the mean of values from three experiments, and error bars represent standard deviation.

**Table 1.** Effects of metal ions on the activity of L-arabinose isomerase from *K. pneumoniae*.

Metal Ion	Relative Activity (%)
Ba <sup>2+</sup>	82
Ca <sup>2+</sup>	101
Co <sup>2+</sup>	105
Cu <sup>2+</sup>	56
Fe <sup>2+</sup>	94
Mg <sup>2+</sup>	115
Mn <sup>2+</sup>	128
EDTA	6
Negative control	100

### 3.3. Substrate Specificity of L-Arabinose Isomerase from *K. pneumoniae*

The substrate specificity of L-arabinose isomerase from *K. pneumoniae* was investigated using various pentoses such as L-arabinose, D-xylose, L-ribulose, and D-xylulose and hexoses such as D-galactose, D-glucose, D-tagatose, and D-fructose (Table 2). The enzyme activity was the highest for L-arabinose, followed by D-galactose, L-ribulose, D-xylulose, D-xylose, D-tagatose, and D-glucose. The activity was generally higher for pentose than hexose except for D-galactose; the activity for L-arabinose was 3.15 times higher than that for D-galactose. However, the activity against D-tagatose, a product of D-galactose, was only 4.3% of that of D-galactose.

**Table 2.** Substrate specificity of L-arabinose isomerase from *K. pneumoniae*.

	Substrate	Product	Relative Activity (%)
Pentose	L-Arabinose	L-Ribulose	315.6
	D-Xylose	D-Xylulose	10.2
	L-Ribulose	L-Arabinose	30.2
	D-Xylulose	D-Xylose	27.6
Hexose	D-Galactose	D-Tagatose	100.0
	D-Glucose	D-Fructose	2.4
	D-Tagatose	D-Galactose	4.3
	D-Fructose	D-Glucose	ND

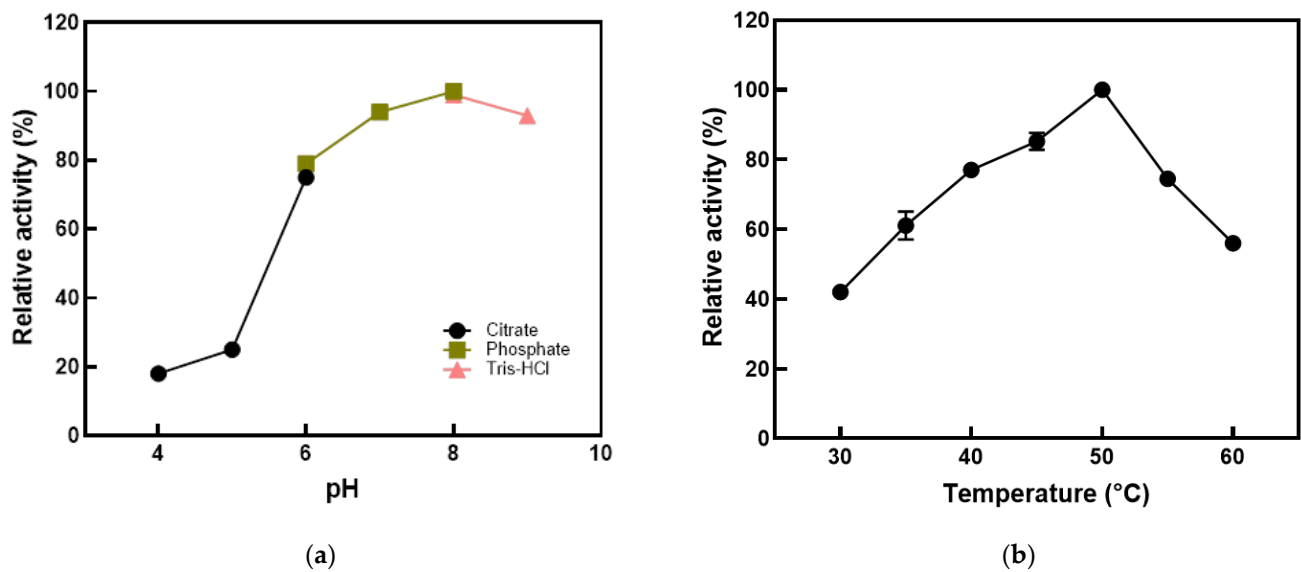

ND, not detected.

### 3.4. Optimization of Reaction Conditions Using *E. coli* Cells Expressing L-Arabinose Isomerase from *K. pneumoniae*

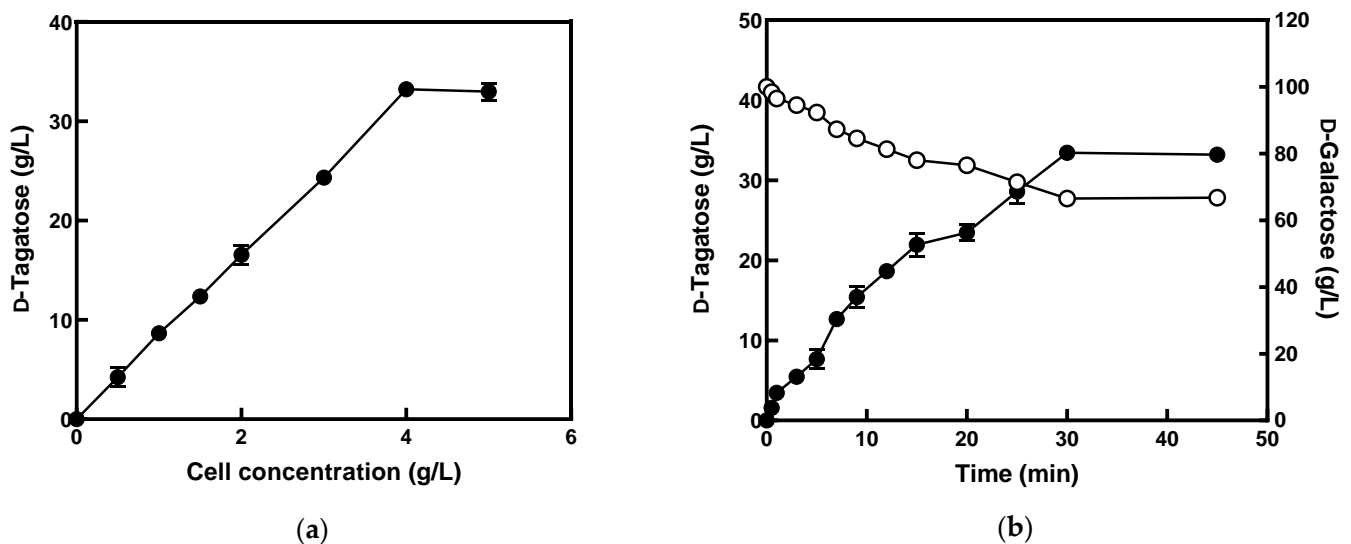

To produce D-tagatose from D-galactose, reaction conditions such as pH, temperature, and cell concentration were optimized using recombinant *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae*. The maximum activity of the recombinant *E. coli* cells was observed at pH 8.0, the same as the enzyme, and 50 °C (Figure 4), 10 °C higher than that of the enzyme (Figure 2).

After incubation for 5 h at 50 °C, the activity of the recombinant *E. coli* cells was more than 60%, which was approximately three-fold higher than that of the enzyme after 5 h at 40 °C (Figure 3). Therefore, the optimal temperature for producing D-tagatose from D-galactose using recombinant *E. coli* cells was determined to be 50 °C.

The production of D-tagatose from D-galactose was further optimized by varying the concentration of the recombinant cells (Figure 5a). The production increased with an increase in the concentration of cells up to 4 g/L and reached a plateau above that concentration, indicating that the optimum concentration for the recombinant *E. coli* cells was 4 g/L.

**Figure 4.** Investigation of pH and temperature to optimize the production of D-tagatose from D-galactose by *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae*. (a) Investigation of pH. The reactions were performed in 50 mM citrate (pH 4.0–6.0), phosphate (pH 6.0–8.0), and Tris-HCl (pH 8.0–9.0) buffers containing 20 g/L D-galactose and 1 g/L cells at 40 °C for 10 min. (b) Investigation of temperature. The reactions were performed in 50 mM phosphate buffer (pH 8.0) containing 20 g/L D-galactose and 1 g/L cells at different temperatures, ranging from 30 °C to 60 °C for 10 min. Data represent the mean of values from three experiments, and error bars represent standard deviation.

**Figure 5.** Production of D-tagatose from D-galactose by *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae*. (a) Effect of the concentration of *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae* on D-tagatose production. The reactions were performed in 50 mM phosphate buffer (pH 8.0) containing 100 g/L D-galactose at 50 °C with varying concentrations of cells from 0.5 to 5 g/L. (b) Time-course reactions for the production of D-tagatose (black circle) from D-galactose (white circle) by *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae*. The reactions were performed in 50 mM phosphate buffer (pH 8.0) containing 100 g/L D-galactose and 5 g/L cells at 50 °C. Data represent the mean of values from three experiments, and error bars represent standard deviation.

### 3.5. Production of D-Tagatose from D-Galactose Using *E. coli* Cells Expressing L-Arabinose Isomerase from *K. pneumoniae*

The optimal reaction conditions for producing D-tagatose from D-galactose were pH 8.0, 50 °C, and 60 g/L recombinant *E. coli* cells using 100 g/L D-galactose with 1 mM  $Mn^{2+}$ . Under these conditions, the time-course reaction for producing D-tagatose from D-galactose was performed by *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae* (Figure 5b). The recombinant *E. coli* cells produced 33.5 g/L D-tagatose for 30 min with a molar yield of 33.5% and a productivity of 67 g/L/h.

L-Arabinose isomerases from *G. stearothermophilus* and *T. neapolitana* have been applied to recombinant *E. coli* cells and immobilized for better D-tagatose production [45,46]. In addition, D-tagatose has been produced from milk whey powder using recombinant *E. coli* cells expressing L-arabinose isomerase from *Lactobacillus plantarum* [47] and from maltodextrin by multienzyme coexpression system of *E. coli* cells containing L-arabinose isomerase [48]. Therefore, further studies on applying immobilization and multienzyme system to *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae* will enhance its industrial applicability.

## 4. Conclusions

In this study, we cloned and characterized L-arabinose isomerase from *K. pneumoniae* as a purified enzyme, which existed as a homohexamer of 336 kDa and exhibited a specific activity of 1.8 U/mg for D-galactose and maximal activity at pH 8.0 and 40 °C with 1.0 mM  $Mn^{2+}$ . Recombinant *E. coli* cells expressing L-arabinose isomerase from *K. pneumoniae*, displaying higher stability than the enzyme, were used to produce D-tagatose from D-galactose; they produced 33.5 g/L D-tagatose with a molar yield of 33.5% and a productivity of 67 g/L/h under the optimal conditions. These findings will be helpful for the industrial production of D-tagatose using a whole-cell reaction.
