Abstract: Existing research on integrated innovation primarily focuses on the integration of product functions or technologies in the engineering field, with limited exploration of cross-domain integration of biological knowledge. Various organisms exhibit various advantageous biological characteristics, and the multi-biological knowledge embedded within these characteristics can inspire designers to implement product integrated innovation. Biologically Inspired Design (BID) is a method that seeks inspiration from nature to achieve innovation in the engineering field. However, existing BID processes mainly apply the features of a single biological prototype. Against this background, this paper emphasizes how to achieve cross-domain integrated innovation through multi-biological knowledge. First, a method for generating integrated innovation ideas is proposed, achieved through obtaining biological prototypes and analyzing biological performance. Second, by obtaining the principal solution through the three mapping methods of biological effects, behaviors, and structures, a method for building the conceptual structure of integrated innovation is proposed. Finally, in conjunction with the Theory of Inventive Problem Solving (TRIZ), a product-integrated innovation design process model based on biological inspiration is constructed. The method is validated with an example of a six-legged firefighting robot.

Keywords: integrated innovation; biologically inspired design; conceptual design; TRIZ

1. Introduction

With the shortening of product life cycles and the increase in market uncertainty, rapid identification and resolution of product problems can help companies gain advantageous positions in the market. Integrated innovation is the process of effectively integrating various elements in the product design process based on existing resources and developing new products that meet the needs of users [1]. Current research on integrated innovation mainly focuses on the integration of functions or technologies of products in the engineering field. Knowledge in the biological field can provide designers with innovation inspiration. By fully leveraging advantageous biological characteristics and integrating the biological knowledge embedded in these characteristics into products, it is possible to create new products that satisfy user needs. However, there is currently less research on applying biological knowledge to achieve the cross-domain integrated innovation of products.

Biologically Inspired Design (BID) is a method that applies biological knowledge to achieve innovation [2]. This method advocates seeking inspiration and potential solutions from the biological field to solve design problems in the engineering field [3–5]. In the process of BID, some scholars have employed bio-inspired topology optimization methods to achieve specific functionalities and enhance system compactness and structural compliance of robots, aiming for optimal designs [6,7]. In nature, the multi-biological knowledge possessed by different organisms can provide inspiration for designers to carry out product-integrated innovation. However, the current BID process focuses on applying

the feature of a single biological prototype, and there is a need to seek an innovative design approach that integrates multi-biological features to solve the design problem of a product.

In summary, this paper draws on biological coupling theory to study the mechanism of product-integrated innovation based on biological inspiration. The study uses the Asknature biological knowledge base to search and perform a similarity analysis to obtain similar biological prototypes. Through the evaluation of the advantageous performance of biological prototypes and the judgment of the contribution degree of biological features, an integrated innovation idea generation method based on biological inspiration is proposed. By obtaining principal solutions through three mapping methods of biological effects, biological behaviors, and biological structures, an integrated innovation conceptual structure construction method based on biological feature mapping is proposed. Subsequently, a product-integrated innovation design method based on biological inspiration is generated.

The rest of this paper is arranged as follows. Section 2 introduces the development status of BID and integrated innovation. Section 3 introduces the proposed method and product-integrated innovation design process, including the generation of innovative ideas and the construction of product concept structures. Section 4 uses a six-legged firefighting robot as an example to validate the proposed method.

2. Related Research

2.1. Integrated Innovation

The concept of Integrated Innovation originates from the innovation theory proposed by Schumpeter [8]. Schumpeter proposed that innovation involves the “establishment of a new production function”, essentially implying a novel combination of factors and conditions of production. Integrated innovation during the product design process can effectively amalgamate various innovative elements to optimize the product. Researchers have studied integrated innovation from different perspectives.

From the perspective of product technology, Liu et al. [9] defined technology hybridization as the process of recombining technological bases to achieve integration between product technology properties. They validated this using an example of a traditional Chinese medicine dropping pills defatting machine. Zhang [10] divided the product innovation of technology integration into three stages: technology development, technology integration, and productization. This work suggests that the process of achieving product innovation through technology integration is a dynamic and cyclical evolution.

From the perspective of product function, Teng [11] studied the method of functional integration and analyzed the fire rescue drone, proposing the design process of an intelligent fire rescue drone based on function integration. Through functional analysis and the integration of functional elements, the fire rescue drone achieved functions such as automatic startup, quick charging, and smart capabilities. Chen [12] researched the theory and characteristics of integrated innovation and designed the urban main battle fire truck with integrated innovation, which realized the innovation in the whole vehicle shape, control system, and human–machine interaction. Klaiber et al. [13] described four generic strategies of functional integration derived gradually from differential designs. This study used different strategies to generate solutions in a systematic way. Moreover, these strategies were proposed to save weight, cost, and time for assembly and gain more installation space. Furthermore, scholars have investigated functional integration from several aspects including function fusion, function sharing, and function combination. In the aspect of function fusion, Ding [14] executed a design of function fusion for the fan mechanism and the body structure of a street sweeper truck. After optimization, finite element analysis and modal analysis were performed on the updated structure. The result was a lighter overall vehicle weight, while the performance requirements were still satisfied. Based on the function-oriented search for obtaining knowledge from multiple domains, Liu [15] established a functional design model rooted in the fusion of multi-domain knowledge, which was then employed for function fusion design and structure fusion design. Further, leveraging multi-domain knowledge fusion, Liu proposed a global

idealized design method. When this method was applied to the design of an emergency cup that could desalinate seawater, a highly idealized product solution was achieved. In relation to function sharing, Kalyanasundaram et al. [16] proposed a function-based product integration approach. A function-sharing matrix and a component-sharing matrix were created based on the reconfigurable principle to identify the shared functions and components of two products. After that, a new product was obtained by combining the functional structure of the integrated product. The approach focused on assessing the feasibility of integrating two existing single-state products to produce a new reconfigurable or multifunctional product. Frohlic et al. [17] proposed a design method for multi-functional products, which can achieve different functions through a single structure. In terms of function combination, Liu et al. [18] analyzed the evolution process of product functional systems and proposed that implementing function combination must satisfy two principles: function complementarity and technology sharing. They established a model for the product-integrated innovation design process based on function combination and the Theory of Inventive Problem Solving (TRIZ). The feasibility of this model was verified through an innovative design instance that integrated straighteners and curlers into one product. Jiang et al. [19] presented the establishment of a functional combination matrix to innovatively form various products and enrich the product system through the combination and collocation of functions. Cao et al. [20] proposed a design process for function combination. They analyzed the combination relationship between each sub-function by decomposing the function of the product technology system and selected a function combination solution according to the market demand. Lu et al. [21] proposed a method for product function combination based on the functional structure and design matrix. This approach integrates multiple product functions into a single product.

From a biological perspective, Hou et al. [22] summarized different function combination patterns including, chain-like, tree-like, and cyclic based on multi-biological effects, and proposed a product design method based on function combination. This method was used to design a tent that could collect fresh water. Liu et al. [23] drew on the concept of biological gene recombination to research a product gene model suitable for product function hybridization, as well as a product gene recombination method, and then established a product functional hybridization design process model.

Most existing research on integrated innovation primarily generates integrated ideas by leveraging knowledge from the engineering field, with a focus on the integration of functions or technologies within products. Organisms have excellent biological features after hundreds of millions of years of evolutionary history. By introducing these biological features into product design and integrating them with the product, this approach has the potential to improve existing systems to form new products. It also provides new ideas and directions for solving complex design problems. However, fewer studies are available on the application of biological knowledge to achieve the cross-domain integration of products.

2.2. Biologically Inspired Design

An analogy, a cognitive process rooted in the similarity between two objects, facilitates the transfer of knowledge from the source to the target, thereby effectively guiding and nurturing creative potential [24]. Analogical design is a method that applies analogical thinking to product design. Moreno [25] argued that analogical design is a process that assists designers in identifying relevant cases, scenarios, and experiences to solve problems. Liu [26] suggested that research on analogical design has mainly focused on three aspects: the representation of analogical knowledge, retrieval of design analogies, and the transfer of analogical knowledge. Broadly speaking, analogical design can be divided into intra-domain analogical design and cross-domain analogical design [27]. In cross-domain analogical design, where the source of the analogy and the design target originate from different fields, innovation efficiency can be significantly enhanced, and the level of innovation elevated [28,29].

BID represents a method of cross-domain analogical design, stressing the emphasis on innovative design over mere imitation and replication of biological phenomena [30]. Existing research categorizes BID into two types: single-source analogy and multi-source compound analogy. Single-source analogy generates solutions based on a single biological prototype, while multi-source composite analogy generates solutions based on multiple biological prototypes.

In terms of single-source analogy, Wang [31] combined bionics with reconfiguration design and established a product innovation design process model. The biological prototype with the highest similarity was selected, and through a transformation model, the features of the biological prototype (including function, strategy, behavior, and structure) were transferred layer by layer to the product technology system. This process enhances the practicality and applicability of the design method. Liu [32] proposed a biological coupled function extension tree model, leveraging extenics and coupled bionics. The biological coupling elements were transferred by calculating their contribution, and the cicada wing with the highest similarity was used as a bionic example to solve some problems with the radiation well horizontal drilling machine. This underscores the practical effectiveness of applying biological prototypes to engineering problem-solving. Ji [33] mapped from the functional level to transfer the biological problem solution to the engineering field, and the problem of the poor portability of helmets was solved using an armadillo shell structure as an example. This method highlights the process of transforming biological features into practical product advantages. Liu [34] used bionics, extenics, and BioTRIZ for product innovation design, creating an extension model for the product and the biological prototype with the greatest similarity to the product. The transfer of coupled elements was carried out through conflict matrix resolution and the importance judgement of biological coupled elements. This approach emphasizes the importance of integrating multidisciplinary methods in product innovation. Chen et al. [35] selected the biological prototype with the highest similarity to the product as the biomimetic object. Utilizing the biological system database, the product system database, and the collaborative middleware database, they mapped the technology system from four levels of the biological system (function, principle, action, and structure). By integrating the inherent relationships across various levels of the technology system, they were able to derive product solutions. This study highlights the inspiration of integrating information from multiple sources in the design process. Liu et al. [36] utilized multi-biological effects for functional problem-solving. Through the effect transformation method of biological prototypes, they rapidly converted the biological prototype with the highest similarity into a product that met market demand, highlighting the potential of single-source analogy in enhancing product functionality.

In terms of multi-source compound analogy, Goel [37] provided a process description for compound analogy design, utilizing the analysis of various BID process instances. In the process of problem-solving, if the problem can be decomposed, the problem can be divided into sub-problems. Assuming the problem decomposes along the function, the designers identified similar biological instances by searching for each sub-function, thereby obtaining a solution for each sub-function. These solutions were then combined to generate an overall engineering solution. When the problem is not decomposable, a solution is directly formulated by searching for biological instances that resemble the problem itself. Liu et al. [38] performed feature clustering for the main functions of the target product. The corresponding multi-biological effects were obtained by retrieving each feature term, and the optimal biological effect was selected for the solution of the product problem to obtain the technical solution. Hou [39] proposed a breakthrough innovation design approach based on multi-biological effects. The general function of the product was decomposed to the functional element, and the functional elements were searched in the multi-biological effect knowledge base to obtain corresponding biological prototypes and multi-biological effect principal diagrams. Finally, the principal solution of the product was obtained through screening and combination. This approach utilizes multiple biological effects to deconstruct product functions, search for biological prototypes,

and combine them to drive breakthrough innovation in product design. Liu et al. [40] proposed a bionic design strategy based on the function combination. They combined the new functions generated by various bionic design methods with each other to enhance the quality of the product. This highlights the substantial influence of multi-source compound analogies on function innovation. Bhasin et al. [41] introduced a tool for BID, termed as the Reduced Function-Means (RF-M) tree. The RF-M tree could illustrate the interactions among functions, behaviors, and structures in biological systems. They also proposed a problem-driven BID method. This method combined RF-M trees from multiple biological prototypes to achieve function sharing. This study provides a robust method for supporting problem-driven biomimetic design.

BID introduces novel solutions to product design by leveraging cross-domain knowledge analogies. In the BID process, most designers use a single biological prototype feature with the highest similarity for analogical transfer when solving sub-functions or functional elements. However, reliance on a single biological prototype may fail to fully exploit the diversity of organisms, which could lead to unresolved design issues, or the solution put forth by the single biological prototype might not represent the optimal choice.

2.3. Summary of the Literature Review

In summary, BID applies biological knowledge to address engineering challenges, whereas integrated innovation amalgamates solutions from various fields to foster innovation. By intertwining BID with integrated innovation, cross-domain knowledge can be utilized to rectify product issues, consequently enhancing product performance. Additionally, this amalgamation can further optimize resource utilization, fostering the development of more innovative products. The focal point of this article lies in implementing cross-domain integrated innovation through the application of multi-biological knowledge. Specifically, the generation of integrated innovative concepts and the establishment of an integrated innovation conceptual framework are paramount to the entire innovation design process.

3. Proposed Methods

3.1. Integrated Innovation Mechanism Based on Biological Inspiration

3.1.1. Acquire Problem Performance of Products Based on Root Cause Analysis

A product, as a technological system, exhibits specific performance. Performance is characterized by the technical attributes of the system during function implementation [42,43], stemming from functional objects, functional carriers, or their interactions. The performance of the product influences customer satisfaction. In this study, the term ‘problem performance’ is used to describe the aspect of a product’s performance that fails to meet user needs.

Using the problem performance of a product as a bridge for analogical design, it is essential to seek biological prototypes in the biological field that have advantageous performance opposite to the problem performance. The advantageous features inherent to the biological prototype are transferred to the engineering domain to solve problem functional elements. Identifying the problem performance of the product allows designers to gain a precise understanding of the issue, serving as the foundation for obtaining the appropriate biological prototype.

In this study, root cause analysis tools were employed to identify the components causing the issue and their corresponding problem attributes, thus leading to the identification of the problem performance of the product. Problem attributes comprise the intrinsic attributes and the variable characteristics of components or supersystems [44]. The process of identifying the problem performance of the product is illustrated in Figure 1.

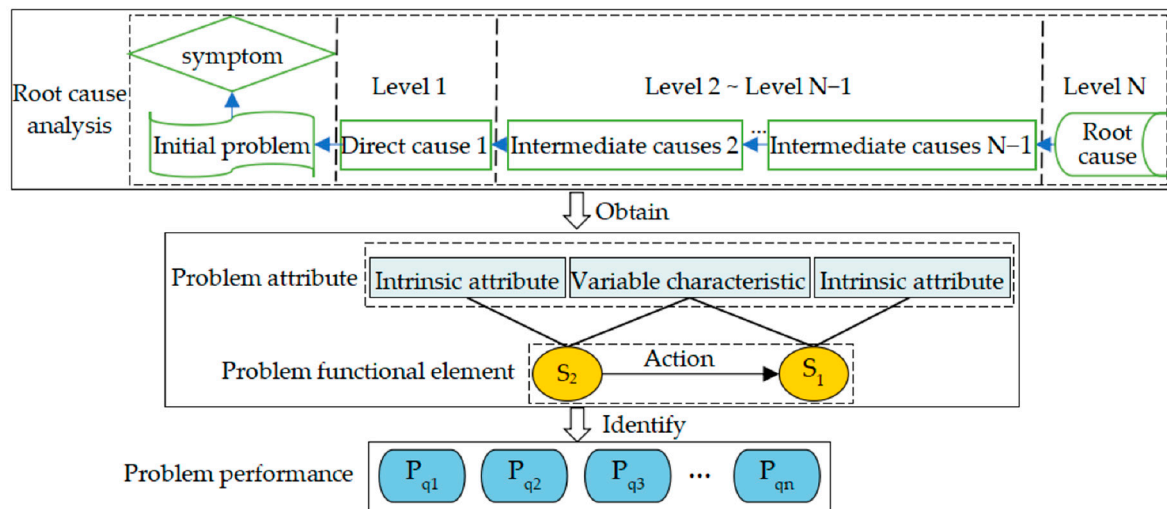

Figure 1. The process of identifying product problem performance.

3.1.2. Biological Coupling Analysis

Through extended evolutionary processes, organisms have refined their capacity to adapt to environmental changes. They exhibit outstanding biological characteristics that enable the achievement of functional elements akin to those of the product, thus displaying advantageous performance [45]. The advantageous performance exhibited by biological prototypes is a result of their unique biological features. For example, black thick-tail scorpions live in desert environments and have evolved unique biological features enabling them to resist erosion from wind-blown sand [46], thereby exhibiting advantageous anti-erosion performance. Different biological prototypes display varying degrees of advantageous performance while accomplishing the same function. Additionally, the impact of the biological features on actualizing the advantageous performance of the biological prototype varies. The extent of this impact depends on the degree of contribution of the biological features toward achieving that function.

The realization of biological functions is seldom accomplished by a single part of an organism or a single factor but is the result of the synergistic interaction of two or more different parts of an organism or the coupling of different factors, and this coupling phenomenon is prevalent in biology [47], as shown in Figure 2. Biological coupling elements are various factors that contribute to biological functions and are the basic units that constitute biological coupling [48]. This study employs the biological coupling analysis method to examine the biological features inherent in biological prototypes that display advantageous performance and assess the degree of contribution of biological features. These biological features encompass biological effects, behaviors, and structures (including structural distribution, morphology, constituent materials, and inter-structural relationships).

Figure 2. Realization model of biological function.

3.1.3. Integrated Innovation Mechanism Based on Multi-Biological Knowledge Inspiration

The integrated innovation mechanism inspired by multi-biological knowledge is an innovation process that integrates multi-biological features with products. This process commences with the existing issues of the product, selects advantageous biological features via acquiring biological prototypes and analyzing biological performance, and then

integrates the selected multi-biological features into the product to form a new product. Its implementation principle is shown in Figure 3, and the specific process is as follows.

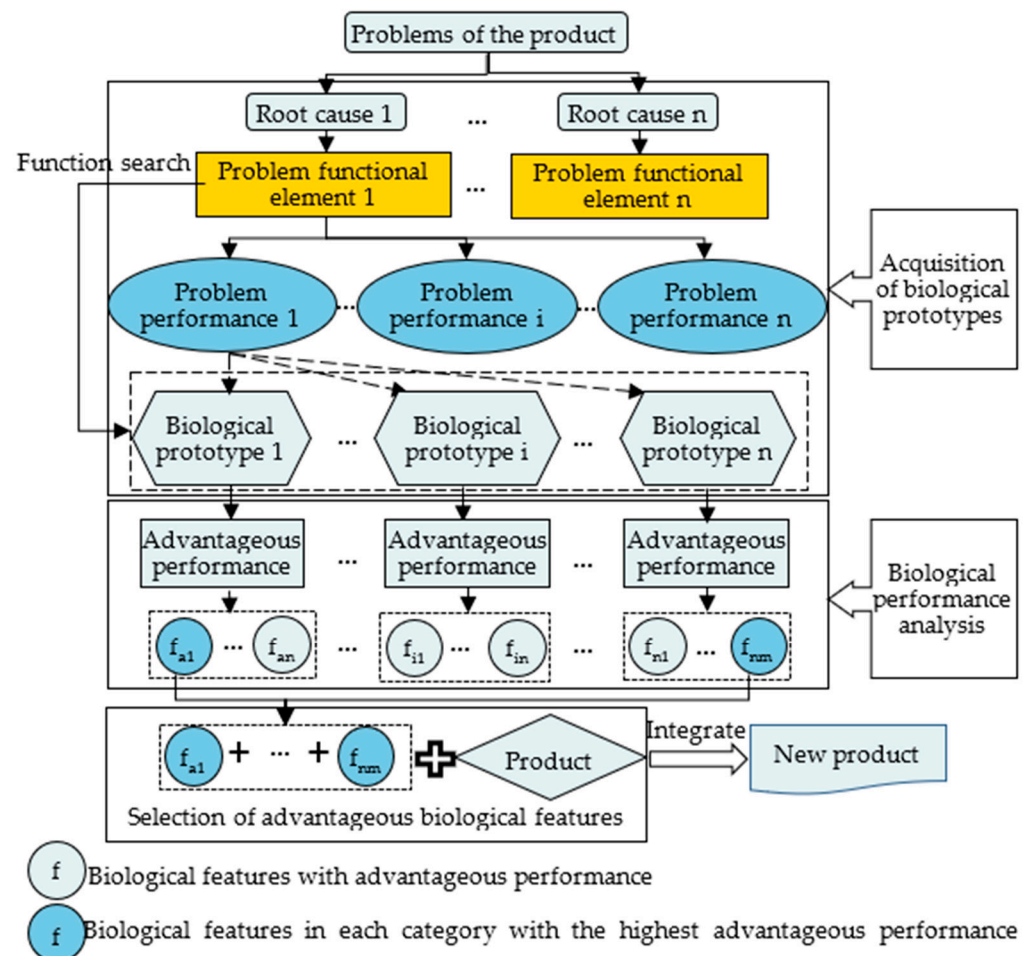

Figure 3. Realization model of biological function.

First, the process starts with the problems of the product. Problem functional elements and their attributes are identified through root cause analysis, culminating in the discernment of the product's problem performance. Utilizing the biological knowledge base to search for the problem function element, multiple biological prototypes are obtained. Subsequently, the degree of advantageous performance displayed by these biological prototypes is assessed. The biological features inherent to the prototypes that display advantageous performance, along with the contribution of these features, are analyzed using the biological coupling analysis method. Furthermore, the extent to which the biological features influence the advantageous performance is analyzed. If the features possessed by different biological prototypes exhibiting advantageous performance belong to the same category—for example, if they all belong to the morphological category—then the value of the degree of influence of this feature on the advantageous performance of these biological prototypes, i.e., the advantageous performance impact value, is not necessarily the same. The higher the value of the biological feature, the more effective it is for solving the problems of the product and has the potential to further improve the performance of the product. Ultimately, the biological feature in each category with the highest advantageous performance impact value is selected and integrated with the product to solve the problem functional element.

3.2. Method of Generating Integrated Innovation Ideas Based on Biological Inspiration

3.2.1. Acquire Similar Biological Prototypes

Functional similarities exist between the biological prototype and the product. Upon identifying the problem functional element through root cause analysis, this paper utilized the Asknature biological knowledge base to search for related functions and thus acquire biological prototypes. Based on this, a similarity analysis was conducted for the biological prototypes. The similarity between the biological prototypes and the product was categorized into three levels: level I, level II, and level III, where level I represents the highest level of similarity, as shown in Table 1. The impact on the product varies when integrating the biological features, depending on the level of similarity.

Table 1. Similarity classification.

Similarity Level	Specific Interpretation
Level I	Similar function, different effects, behaviors, and structures
Level II	Similar function, same effect, different behaviors and structures
Level III	Similar function, same effect, similar behavior, different structures

The similarity of the functional elements and the similarity of the behavioral elements were evaluated by calculating the similarity values of the similar elements. Here, the similar element is represented as u_i , and the similarity value is determined by calculating $Sim(u_i)$, as shown in Equation (1), where ω_j denotes the weight of the evaluation index, and $Gra(k_j)$ is the similarity value between two similar indexes. The calculation formula for $Gra(k_j)$ is shown in Equation (2), where $v \in \{0.1, 0.2, \dots, 0.9\}$. Elements are considered similar if $Sim(u_i) \geq 0.6$.

$$Sim(u_i) = \sum_{j=1}^9 \omega_j Gra(k_j) (i = 1 \sim l) \quad (1)$$

$$Gra(k_j) = \begin{cases} 1 & \text{The content of similar indicators is same} \\ v & \text{The content of similar indicators is similar } (j = 1 \sim 9) \\ 0 & \text{The content of similar indicators is different} \end{cases} \quad (2)$$

The similar functional element is represented as $u_i(F_p, F_{bi})$, evaluated through 10 indicators: functional carrier, action, functional object, input energy, input substance, input signal, output energy, output substance, output signal, and environment. The weight attributed to each indicator is represented by ω_A , where, $\omega_A = \{\omega_1, \dots, \omega_i, \dots, \omega_{10}\}$. The similar behavior element is represented as $u_i(B_p, B_{bi})$, evaluated through 8 indicators: dominant object, actuated object, action, accepting object, pre-dominance state and post-dominance state of the dominant object, and pre-acceptance state and post-acceptance state of the accepting object. The weight assigned to each of these indicators is represented by ω_B , where $\omega_B = \{\omega_1, \dots, \omega_i, \dots, \omega_8\}$.

In order to better integrate this method into industrial design, this paper provided the fundamental factors for evaluating the similarity values of functional similarity indicators, as shown in Table 2, as well as the fundamental factors for evaluating the similarity values of behavioral similarity indicators, as shown in Table 3. When applying this method to industrial design, it is crucial to ensure that the data are standardized and normalized initially. This enhances comparability among different data sets, making weight calculations more accurate and rational. Furthermore, during the early stages of design, models or simulations can be employed to validate the results of similarity assessments. By fabricating design prototypes or testing them within virtual environments, the accuracy of evaluation data can be verified, and necessary adjustments made. Additionally, close collaboration with domain experts is essential to ensure the validity and practical applicability of assessment data.

Table 2. Fundamental factors for evaluating the similarity values of functional similarity indicators.

Similarity Indicator	Fundamental Factor
Functional carrier	Carrier shape, carrier structure, carrier material, carrier physical characteristics, etc.
Action	Types of action, effectiveness of action, efficiency in generating action, precision of action, etc.
Functional object	Characteristics of the functional object, scope of applicability, etc.
Input energy	Types of energy requirements, energy consumption analysis, etc.
Input substance	Comparison of substance requirements, types of substances, proportion of substance composition, etc.
Input signal	Signal control method, signal compatibility, signal input mode, signal control characteristics, etc.
Output energy	Types of energy output, energy output efficiency, energy output level, etc.
Output substance	Types of products, composition of products, characteristics of products, etc.
Output signal	Types of signals, signal strength, signal matching degree, etc.
Environment	Temperature, humidity, air composition, geological characteristics, etc.

Table 3. Fundamental factors for evaluating the similarity values of behavioral similarity indicators.

Similarity Indicator	Fundamental Factor
Dominant object	The types and characteristics of objects (shape, size, etc.), the ability and features to control or perform tasks, and the similarity of control methods (utilizing muscles, electronic components, etc.).
Actuated object	The types and characteristics of objects, the initiation method of behavior (muscle contraction, electronic signals, etc.), and the relative position and relationship of the acting objects.
Action	The types of actions (movement, deformation, transmission, etc.), the speed, precision, and fluidity of actions, and the complexity and adaptability of actions.
Accepting object	The types and characteristics of the accepting object, the sensitivity of the accepting object to external influences, and the position and relationship of the accepting object.
Pre-dominance state of dominant object	The state characteristics of the dominant object (position, shape, etc.), the preparatory state and conditions before behavior execution.
Post-dominance state of dominant object	The state characteristics of the dominant object (position, shape, etc.), changes and effects after behavior execution.
Pre-acceptance state of accepting object	The state characteristics of the accepting object (position, shape, etc.), the state and conditions before behavior execution.
Post-acceptance state of accepting object	The state characteristics of the accepting object (position, shape, etc.), changes and effects after behavior execution.

3.2.2. Method of Generating Integrated Innovation Ideas Based on Biological Performance Analysis

1. Evaluate advantageous performance of biological prototypes

Various biological prototypes exhibit different degrees of advantageous performance in performing the same function. The advantageous performance of a biological prototype is influenced by the intrinsic attributes of the functional carrier, action, and functional object. An advantageous performance value evaluation index based on these attributes was established, as shown in Table 4. Performance values have been categorized into five ascending levels: 1, 3, 5, 7, and 9.

Table 4. Advantageous performance value evaluation index based on attributes.

Influence Factor	Advantageous Performance Evaluation Indicator	Performance Value
Functional carrier	Intrinsic attributes of functional carrier (diameter, number, etc.)	5 grades
	Intrinsic attributes of functional object (diameter, number, etc.)	
Action	Environmental attributes (humidity, temperature, pressure, etc.)	5 grades
	Variable characteristics of functional carrier (adsorption, pressure, state, etc.)	
	Variable characteristics of functional object (adsorption, pressure, state, etc.)	
	Behavioral attributes (behavioral state, speed, time, etc.)	
Functional object	Intrinsic attributes of functional object (diameter, number, etc.)	5 grades

2. Judge the contribution degree of biological features

The advantageous performance exhibited by an organism when carrying out a function is the result of multi-biological features working in concert. However, the contribution of each biological feature toward realizing that function varies. Determining the contribution degree of biological features is a prerequisite for calculating the advantageous performance impact value. In this study, the analytic hierarchy process (AHP) [49,50] was employed to determine the contribution degree of biological features, and the steps are as follows:

Step 1: Establish the set $X = \{x_1, x_2, \dots, x_n\}$ of each biological feature that contributes to the realization of the function of the biological prototype, where n denotes the number of biological features.

Step 2: Analyze the biological features and list the judgment matrix A . The element x_{ij} in matrix A indicates the importance degree of biological feature x_i ($1 \leq i \leq n$) relative to biological feature x_j ($1 \leq j \leq n$). Its value ranges from 1 to 9. x_{ij} is assigned a value depending on the varying degrees of importance, with the value increasing as the importance difference between two biological features grows. Here, 1 indicates that two biological features share equal importance, while 9 signifies that one biological feature is of extreme importance relative to the other. If the biological feature x_i is compared with x_j to get x_{ij} , then the biological feature x_j is compared with x_i to obtain $x_{ji} = 1/x_{ij}$.

Step 3: Compute the maximum eigenvalue λ_{max} of matrix A and its corresponding eigenvector G and perform a consistency check. Normalize the eigenvector to obtain the contribution value of the biological features. The steps for consistency check are as follows:

1. Calculate the consistency index (CI), as shown in Equation (3).

$$CI = \frac{\lambda_{max} - n}{n - 1} \quad (3)$$

where λ_{max} is the maximum eigenvalue of the judgment matrix and n is the order of the judgment matrix.

2. The mean random consistency index (RI) is obtained by looking up the table. The values of the 1~10 order judgment matrices are shown in Table 5.

Table 5. Mean random consistency index.

n	1	2	3	4	5	6	7	8	9	10
RI	0.00	0.00	0.52	0.89	1.12	1.24	1.36	1.41	1.46	1.49

3. Calculate the consistency ratio (CR), as shown in Equation (4).

$$CR = \frac{CI}{RI} \quad (4)$$

When $CR < 0.1$, it is generally believed that the consistency of the judgment matrix is acceptable; otherwise, the judgment matrix should be appropriately corrected.

3. Generate integrated ideas

After assessing the advantageous performance of the biological prototype and appraising the contribution degree of its features, the advantageous performance impact value of the biological features was calculated. This study then integrated the biological features from different prototypes, which possess the highest advantageous performance impact value in each type of feature, to form the integration idea. The specific steps are as follows:

Step 1: Utilizing the root cause analysis tool, the current product issues were analyzed to determine the root causes. After identifying the root causes, this study analyzed the problem performance when the product accomplishes its functional elements. The problem performance may be caused by a functional carrier, action, or functional object.

Step 2: Assess the advantageous performance of the biological prototype. Each biological prototype exhibits advantageous performance in achieving similar functions as opposed to problem performance, and the degree of advantageous performance differs among prototypes. The advantageous performance caused by the functional carrier, action or functional object of the biological prototype, was scored according to Table 2.

Step 3: Analyze the biological features that the biological prototype possesses when exhibiting advantageous performance in implementing similar functions. Make judgments on the contribution degree of these features and establish a score table for the contribution degree of biological features.

Step 4: Establish a score table for the advantageous performance impact value of the biological features. The advantageous performance impact value of the biological feature is denoted as V_i , the advantageous performance value of the biological prototype is denoted as V_p , and the contribution degree of the biological feature is denoted as D_c . Calculate the V_i , as shown in Equation (5).

$$V_i = V_p \times D_c \quad (5)$$

Step 5: Generate integration ideas. For a single problem functional element, the integratable biological features from biological prototypes exhibit variability across different similarity levels. The difference between similarity level I and the other two levels resides in the effect. Therefore, the obtained biological prototypes are classified based on their effect. Within prototypes with the same effect, the features with the highest advantageous performance impact value are chosen from each feature category to be integrated with the product. If the highest level of similarity is I, multiple integrated ideas with different effects can be generated. If the highest level of similarity is II, multiple integrated ideas with different behaviors can be generated. If the highest level of similarity is III, multiple integrated ideas with different structures can be generated. If the root cause corresponds to multiple problem functional elements, establish a morphological matrix corresponding to the integrated ideas.

4. Select integrated idea

The practical degree parameter (P_{di}) is used to select the integration idea, as shown in Equation (6). When solving product problems, the higher the overall performance (P_{oi}) of the product and the smaller the degree of change (C_{di}) of the product, the larger the parameter value and thus the greater the practical degree. In the morphological matrix corresponding to multiple problem function elements, the integration idea with the highest value of practical degree parameter in each problem function element is selected to solve the problem.

$$P_{di} = \frac{P_{oi}}{C_{di}} \quad (6)$$

The calculation of the overall performance value of the product is based on the assumption that the integrated idea can be realized. It is the total score obtained by adding the advantageous performance impact values of each biological feature in the integrated idea.

The degree of change of the product is evaluated under the assumption that the integrated idea can be implemented. It can be divided into five categories: relatively small,

small, moderate, relatively large, and large, as shown in Table 6. Scores can be assigned considering three aspects: structure (form, material, and distribution), behavior (direction of movement), and effect. The greater the degree of change, the higher the score.

Table 6. Scoring table of degree of change.

Degree of Change	Level	Score
Structure change, behavior and effect unchanged	Relatively small	1
Behavior change, structure and effect unchanged	Small	3
Structure and behavior change, effect unchanged	Moderate	5
Effect change, other product functions unchanged	Relatively large	7
Effect change, other product functions change	Large	9

3.3. Method of Establishing Integrated Innovation Concept Structure Based on Biological Feature Mapping

3.3.1. The Conversion Process from Integrated Innovation Ideas to Concept Structure

The integrated innovation idea involves integrating biological effects (E_b), biological behaviors (B_b), or biological structures (S_b) with a product. These biological features are individually mapped onto the engineering field and subsequently integrated with the product to build conceptual structure. The transformation process from integrated innovation idea to concept structure is shown in Figure 4.

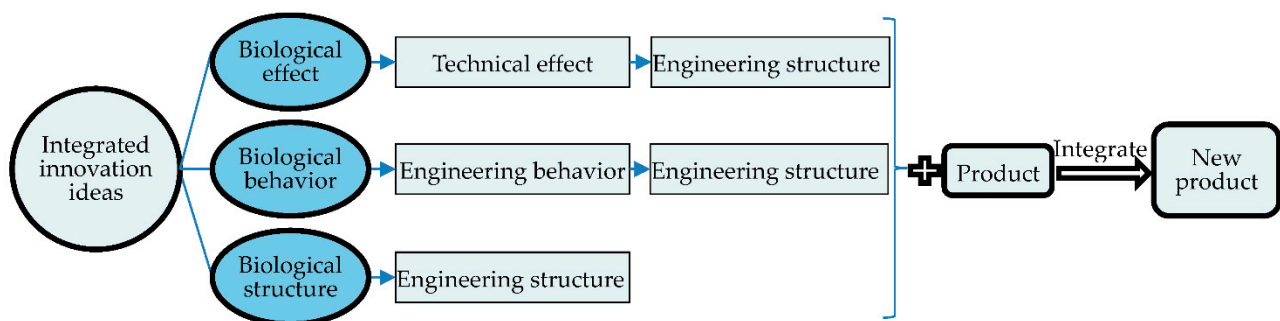

Figure 4. Conversion process from integrated innovation idea to conceptual structure based on biological feature mapping.

In the obtained integrated innovation ideas, if the element to be integrated is a biological effect, the biological effect is mapped to the engineering field to obtain a corresponding technical effect (E_t). Then, the structure in the engineering field corresponding to the technical effect is identified, thereby forming a principal solution based on the E_b - E_t - S_e mapping. If the element to be integrated is a biological behavior, the biological behavior is mapped to the engineering field to obtain a corresponding engineering behavior (B_e). Subsequently, the structure in the engineering field corresponding to the engineering behavior is identified, thereby generating a principal solution based on the B_b - B_e - S_e mapping. If the element to be integrated is a biological structure, the biological structure is mapped to the engineering field. The engineering structure is found or imitated from the biological structure, thereby generating a principal solution based on the S_b - S_e mapping. The principal solutions are then gathered to build the conceptual structure.

3.3.2. Acquire Principal Solution Based on E_b - E_t - S_e Mapping

If the integrated innovation idea includes the integration of biological effects with the product, the engineering structure can be identified through two methods: inspiration or search.

- (1) Inspiration. Researchers study the biological structure that implements a function similar to the problem functional element through the biological effect and seek the corresponding technical effect of the biological effect in the engineering field. Through technical effects and biological structures, designers derive inspiration to identify engineering structures that can achieve similar functions. The process of obtaining the principal solution through inspiration is shown in Figure 5.
- (2) Search. In the engineering field, researchers search for the technical effect corresponding to the biological effect. The technical effect and the problem functional element are expanded using synonyms, near synonyms, or related words, which form the search formula “technical effect + function” in the PatSnap patent database. The obtained patents are clustered and filtered based on design experience to identify engineering structures. During the clustering and filtering process, several different patents are obtained. Taking into account that different patents may correspond to different sub-functions when implementing functions through the same technical effect. In this regard, a morphological matrix is established to obtain the engineering structures that realize the sub-functions. The process of obtaining a principal solution through this search method is shown in Figure 6.

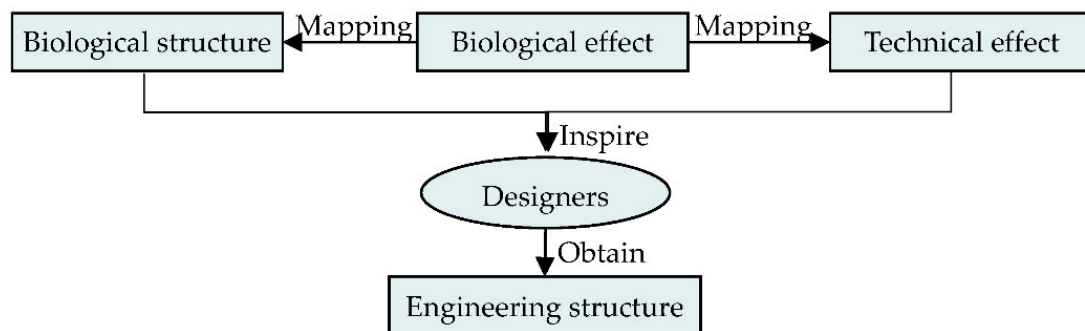

Figure 5. Process of obtaining the principal solution by means of inspiration.

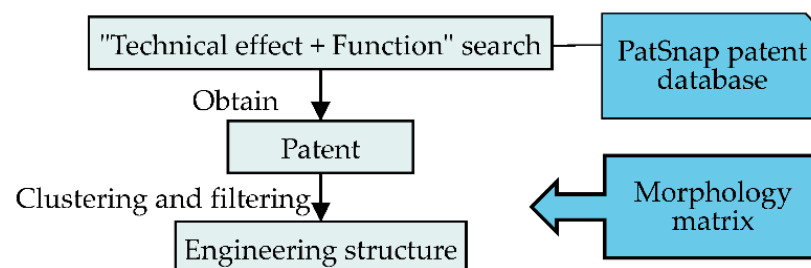

Figure 6. Process of obtaining the principal solution by means of search.

3.3.3. Acquire Principal Solution Based on B_b-B_e-S_e Mapping

If the integrated innovation idea includes the integration of biological behaviors with the product, the engineering structure can be identified through two forms of integration: behavior sharing and behavior addition. Behavior sharing refers to a single component that can perform multiple behaviors. It is determined whether there are components in the product that can perform the behavior to be integrated, and if so, behavior sharing can be achieved. Behavior addition involves adding the behavior to be integrated to the behavior chain to solve product problems. The process of obtaining the principal solution based on B_b-B_e-S_e mapping is shown in Figure 7, and the specific steps are as follows:

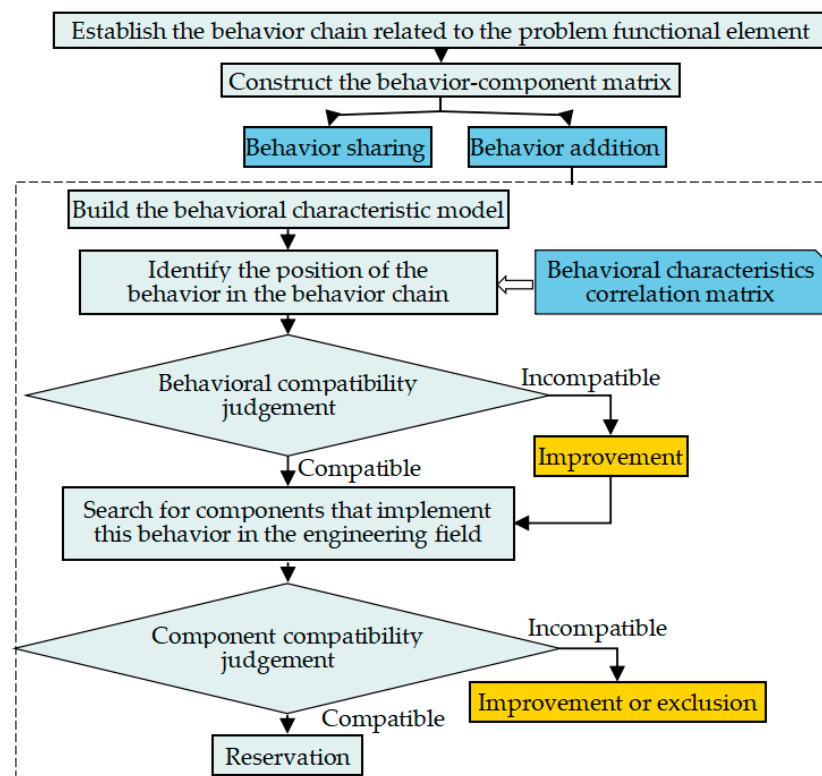

Figure 7. Process of obtaining principal solution based on B_b - B_e - S_e mapping.

Step 1: Establish the behavior chain and the behavior-component matrix associated with the problem functional element.

Step 2: Perform behavior sharing. Determine whether the product component can share the behavior to be integrated, and if there is a component in the behavior-component matrix that can implement the behavior, then the sharing is completed.

Step 3: Perform behavior addition. First, establish the behavioral characteristic model for the behaviors to be integrated, as shown in Figure 8. The dominant object changes the attribute value of the accepting object through its actions, thereby changing the pre-acceptance state and post-acceptance state of the accepting object.

Figure 8. Behavior characteristics model.

Second, determine the position of the behaviors to be integrated in the behavior chain. Considering that the Design Structure Matrix (DSM) is a mathematical tool for describing the complex relationships, interdependencies, and constraints among various design factors (such as design parameters, design activities, etc.) [51], this study established the behavior association matrix with the help of the DSM. The position of the behavior, which is to be integrated, within the behavior chain is determined by comparing the consistency between the pre-dominance and post-dominance status of the dominant object, or the pre-acceptance and post-acceptance status of the accepting object. The behavior association matrix of the behavior to be integrated and the n behavior elements in the behavior chain are shown in Figure 9. In the matrix, B_a represents the behavior to be added, and B_i ($i = 1 \sim n$) represents

the behavior elements in the related behavior chain. In the figure, ‘1’ below the diagonal line indicates a forward contact, ‘1’ above the diagonal line indicates a reverse contact, and ‘blank’ indicates that there is no connection between the behaviors.

	B_a	B_1			B_a	B_i			B_a	B_n
B_a			B_a			B_a		
B_1				B_i				B_n		

Figure 9. Behavior incidence matrix.

If both positions above and below the diagonal line are ‘blank’, it indicates that the behaviors are incompatible. If both above and below the diagonal line are ‘1’, it indicates that the behaviors are coupled. If ‘1’ is below the diagonal line and ‘0’ is above, it indicates a forward series connection of behaviors, represented as $B_i \rightarrow B_a$. If ‘1’ is above the diagonal line and ‘0’ is below, it indicates a reverse series connection of behaviors, represented as $B_a \rightarrow B_i$. The subsequent step is to assess the compatibility of the behavior. If the behavior is compatible, components that can implement this behavior in the engineering domain are sought, followed by an evaluation of component compatibility. If it is not compatible, auxiliary behaviors are added, or the behavior attribute values are modified.

3.3.4. Acquire Principal Solution Based on S_b - S_e Mapping

If the integrated innovation idea includes the integration of biological structures with the product, the principal solutions are procured through structural integration. Structural integration refers to the transference of features such as the morphology, structure, color, and material of biology to the engineering field and then integrated with the product. The process of procuring principal solutions based on S_b - S_e mapping is shown in Table 7.

Table 7. The process of obtaining the principal solution based on S_b - S_e mapping.

Feature	Attribute	Steps of Integration
Biological morphology	Point, line, surface, solid, angle, radian, groove, protrusion, etc.	① Extract attributes of the biological morphology. ② Judge the degree of matching between the feature and the product. ③ Consider the complexity of the process. ④ When the process is not complex, integrate the feature; when the process is complex, improve and then integrate the feature.
Biological color	Hue, saturation, transparency, etc.	① Extract attributes of the biological color. ② Judge whether the color has a negative impact on the product or consumer visual perception (color feedback, symbolic meaning). ③ Consider the complexity of color painting and color matching. ④ When the process is not complex, integrate the feature; when the process is complex, improve and then integrate the feature.
Biological structure	Stability, compactness, solidity/hollow, homogeneity, etc.	① Extract attributes of the biological structure. ② Improve the product structure based on the biological structure. ③ Determine the complexity of the process to improve the product structure. ④ When the process is not complex, integrate the feature; when the process is complex, improve and then integrate the feature.
Biological material	Rigidity, strength, elasticity, plasticity, toughness, weight, etc.	① Extract attributes of the biological material. ② Find the material in the engineering field with similar attributes to the biological material. ③ Replace or combine this material with the original material.

In the methodology proposed in this paper, the conversion of biological features into engineering structures stands as a pivotal stage in the construction of conceptual frameworks. Taking into consideration that within the natural realm, a single biological feature might serve diverse biological functions, integrating this attribute into BID can lead to streamlined system architectures and enhanced operational efficiency. In light of this, the present study introduced a design strategy for incorporating multifunctional shared components in the BID process. The specific steps are as follows:

Step 1: Feature combination analysis. Analyze the distinct characteristics of engineering structures to identify which features can mutually support and enhance each other in a multifunctional shared context.

Step 2: Function correlation analysis. Perform a functional correlation analysis on the engineering structures obtained through mapping and transformation, assessing the mutual influence of different features across various functions. Identify engineering structures suitable for function sharing.

Step 3: Modular design. Based on the characteristics of the engineering structure, conduct modular design by decomposing components of different functions into modules, ensuring each module can effectively achieve specific functionalities.

Step 4: Interaction analysis. Consider information exchange, energy transfer, and potential interference among the modules. Analyze the interactions between different modules to ensure their collaborative operation without conflicts.

Step 5: System integration. Integrate different modules into the overall system, ensuring connectivity and coordination between modules, enabling multi-functional shared components to perform within the entire system.

Step 6: Experimental validation and simulation. Employ experimental validation and simulation methods to verify the performance and stability of components under multi-functional shared conditions.

3.4. Process Model of Product-Integrated Innovation Design Based on Biological Inspiration

The whole design process starts from the problem of the product. Through the acquisition of biological prototypes and biological performance analysis, the features of the biological prototype with the highest advantageous performance impact value are integrated with the product to form integrated innovation ideas. The principal solutions are then obtained through three mapping methods: biological effects, biological behavior, and biological structure, converting the integrated innovation idea into a conceptual structure. The specific steps are as follows:

Step 1: Establish a functional model and identify the root cause of the problem through root cause analysis. On this basis, determine the conflict area where the root cause is located and further determine the problem functional element, as shown in Figure 10.

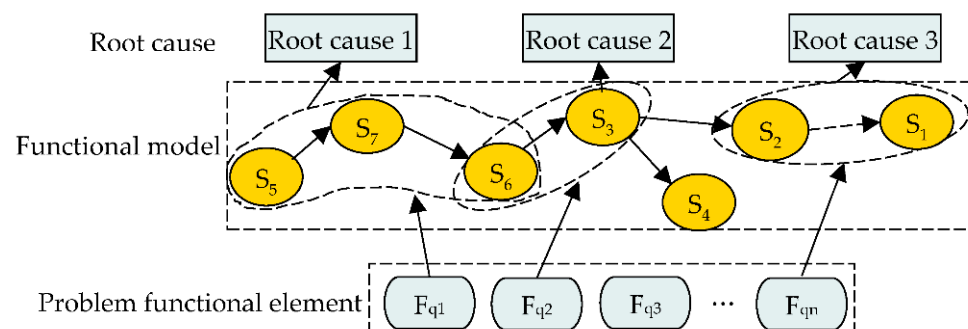

Figure 10. Process of acquiring problem function elements.

Step 2: Acquire similar biological prototypes.

1. Search for biological prototypes based on the problem functional element and establish a search list. In the Asknature biological knowledge base, the problem functional

element is searched using two methods: biomimicry taxonomy and keyword search. If the function belongs to insufficient or excessive function, search for this function or similar functions. If the function is harmful, search for the opposite function.

2. Analyze the functional similarity between the biological prototype and the problem functional element of the product, as well as the behavioral similarity of the behavior corresponding to the realization of the function. Functional similarity is analyzed to determine whether the effect of the biological prototype to achieve this function is the same as that of the product and then to build a list of similarity classification of the biological prototype.

Step 3: Generation of integrated innovation ideas based on biological performance analysis. By evaluating the advantageous performance of similar biological prototypes and judging the contribution degree of biological features, the advantageous performance impact value of biological features is calculated. Integrate the features of the biological prototype with the highest advantageous performance impact value in each category to obtain integrated ideas.

Step 4: Select an integrated innovation idea based on P_{di} .

Step 5: Acquire the principal solution based on biological feature mapping.

Step 6: Summarize the obtained principal solutions, build the morphological matrix, and obtain the preliminary solutions.

Step 7: The method of 'Entropy Weight Method-Grey Relational Analysis' is used to evaluate the preliminary solutions, resulting in the optimal solution.

The entropy weight method is an objective weighting method, which determines the weight of each index according to the amount of information transmitted by each index. The magnitude of the weight reflects the relative competition intensity among the indexes [52]. In this paper, the weights of evaluation indexes were calculated by the entropy weight method, and the specific steps are as follows:

1. Construct the evaluation index matrix. Assume that in the evaluation system with n evaluation indicators and m evaluated objects, the matrix formed by all evaluation scores is denoted as $X = (x_{ij})_{n \times m}$, where x_{ij} ($i = 1, 2, \dots, n; j = 1, 2, \dots, m$) is the score of the j -th evaluated object under the i -th evaluation indicator, as shown in Equation (7).

$$X = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1m} \\ x_{21} & x_{22} & \cdots & x_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ x_{n1} & x_{n2} & \cdots & x_{nm} \end{bmatrix} \quad (7)$$

2. Calculate the weight p_{ij} of the j -th evaluated object under the i -th evaluation indicator, as shown in Equation (8).

$$p_{ij} = \frac{x_{ij}}{\sum_{j=1}^m x_{ij}} \quad (8)$$

3. Calculate the entropy value e_i ($i = 1, 2, \dots, n$) of each indicator, as shown in Equation (9).

$$e_i = -k \sum_{j=1}^m p_{ij} \ln p_{ij}, k = \frac{1}{\ln m} \quad (9)$$

4. Calculate the redundancy d_i of the information entropy for each indicator, as shown in Equation (10).

$$d_i = 1 - e_i \quad (10)$$

5. Calculate the weight ω_i for each indicator, as shown in Equation (11).

$$\omega_i = \frac{d_i}{\sum_{i=1}^n d_i} \quad (11)$$

Grey relational analysis is a method that determines the correlation between curves by comparing the geometric similarity of the comparison sequence curve and the reference sequence curve. The higher the geometric similarity of the two curves, the greater the correlation. Grey relational analysis can also be used for scheme evaluation by calculating the correlation coefficients of different schemes to obtain the correlation degree values and then sorting the values to obtain the optimal scheme [53–55]. Based on the entropy weight method to calculate the weights of evaluation indexes, this article determined the optimal scheme through grey relational analysis, and the specific steps are as follows:

1. Establish the initial decision matrix Y , which involves n samples characterized by m criteria.

$$Y = \begin{bmatrix} y_{11} & y_{12} & \cdots & y_{1m} \\ y_{21} & y_{22} & \cdots & y_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ y_{n1} & y_{n2} & \cdots & y_{nm} \end{bmatrix} \quad (12)$$

2. Standardize the data.

If the maximum value is optimal, standardize the data as shown in Equation (13).

$$y'_{ij} = \frac{y_{ij} - \min_{i=1}^n y_{ij}}{\max_{i=1}^n y_{ij} - \min_{i=1}^n y_{ij}} \quad (13)$$

If the minimum value is optimal, standardize the data as shown in Equation (14).

$$y'_{ij} = \frac{\max_{i=1}^n y_{ij} - y_{ij}}{\max_{i=1}^n y_{ij} - \min_{i=1}^n y_{ij}} \quad (14)$$

3. Construct a standardized matrix by replacing each element in the initial decision matrix Y with the calculation result of y'_{ij} . Calculate the maximum standardized value $y'_o(j)$ for each evaluation indicator, as shown in Equation (15), and use it as the reference value for the j -th evaluation indicator.

$$y'_o(j) = \max_{i=1}^n y'_{ij} \quad (15)$$

4. The difference value $\Delta_{oi}(j)$ between each standardized value and its reference value is calculated, as shown in Equation (16).

$$\Delta_{oi}(j) = |y'_o(j) - y'_{ij}| \quad (16)$$

A difference matrix Δ is created, as shown in Equation (17).

$$\Delta = \begin{bmatrix} \Delta_{o1}(1) & \Delta_{o1}(2) & \cdots & \Delta_{o1}(m) \\ \Delta_{o2}(1) & \Delta_{o2}(2) & \cdots & \Delta_{o2}(m) \\ \vdots & \vdots & \ddots & \vdots \\ \Delta_{on}(1) & \Delta_{on}(2) & \cdots & \Delta_{on}(m) \end{bmatrix} \quad (17)$$

1. Calculate the grey relational coefficient $r_{oi}(j)$ for each element, as shown in Equation (18), to obtain the matrix R .

$$r_{oi}(j) = \frac{\min_{i=1}^n \min_{j=1}^n \Delta_{oi}(j) + 0.5 \times \max_{i=1}^n \max_{j=1}^n \Delta_{oi}(j)}{\Delta_{oi}(j) + 0.5 \times \max_{i=1}^n \max_{j=1}^n \Delta_{oi}(j)} \quad (18)$$

2. Calculate the grey relational degree Γ_{oi} of the scheme, which represents the magnitude of the correlation, as shown in Equation (19). Here, $\omega(j)$ is the weight of the evaluation index obtained by the entropy weight method.

$$\Gamma_{oi} = \sum_{j=1}^m [\omega(j) \times r_{oi}(j)], \sum_{j=1}^m \omega(j) = 1 \quad (19)$$

Step 8: Problem-solving and evaluation of the new concept structure.

Problem-solving and evaluation are performed by applying the optimal solution to establish the new concept structure. Whether there are problems in the new product concept structure is judged. If the answer is yes, the problems are solved according to TRIZ problem-solving tools [56–58]. Then, the improved product concept structure is established.

The process model of product-integrated innovation design based on biological inspiration is shown in Figure 11.

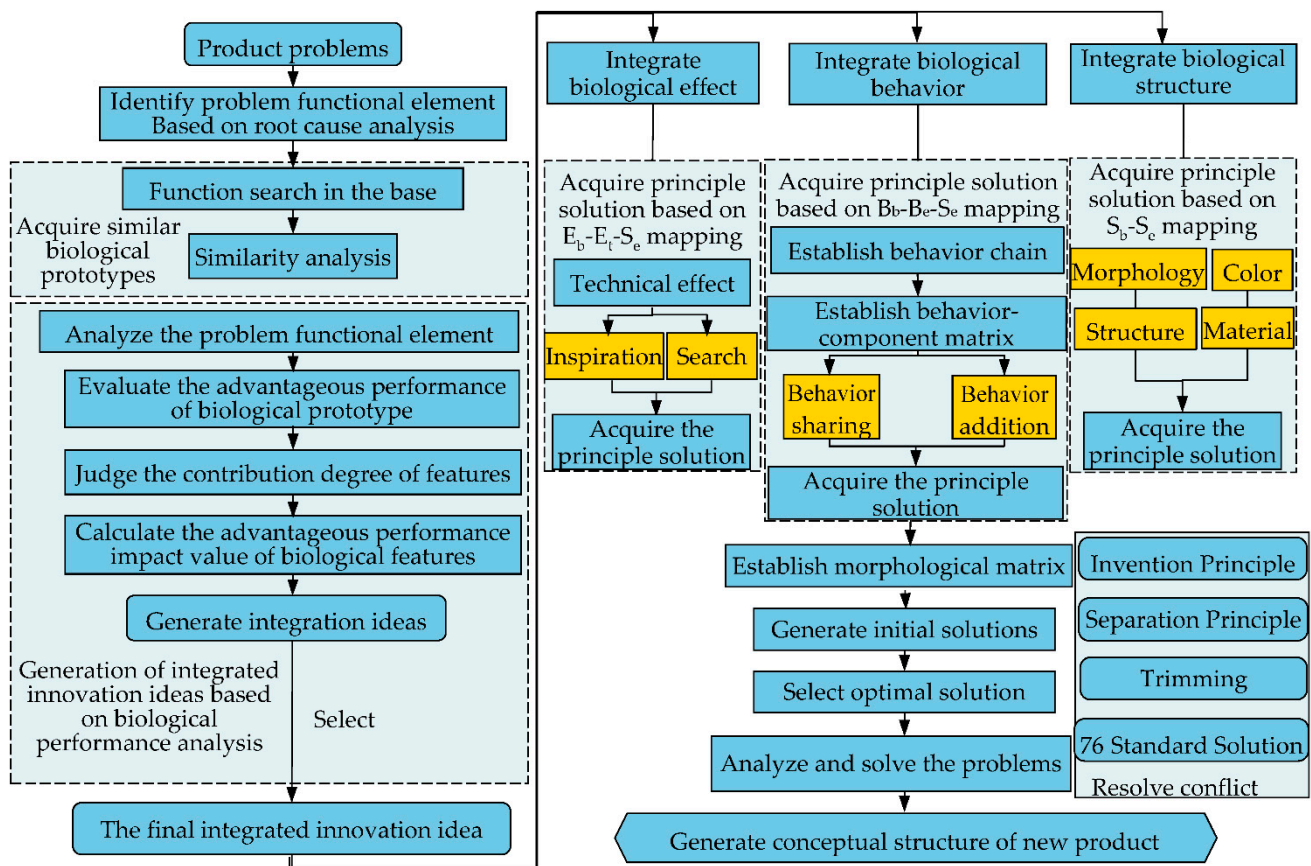

Figure 11. Process model of product-integrated innovation design based on biological inspiration.

4. Case Study

Bio-inspired design has emerged as a transformative approach in the field of robotics, drawing inspiration from natural biological systems to develop innovative and efficient robotic solutions [59]. This methodology leverages millions of years of evolution and adaptation to create robots that possess enhanced capabilities and functionalities. By mimicking the intricate designs and behaviors found in nature, bio-inspired robotics has

brought about a paradigm shift, enabling the development of robots that can excel in complex and dynamic environments.

Bio-inspired robots, founded upon the interplay between information and physical processes, have the capacity to imbue robots with the adaptivity, robustness, versatility, and agility demonstrated by biological organisms [60,61]. Applying these attributes in scenarios such as search-and-rescue missions enables the full utilization of the advantages of bio-inspired robots.

Forest fires possess characteristics of complexity and diversity, resulting in certain limitations for traditional firefighting methods. The application of firefighting robots can address these shortcomings, enhancing the capacity to respond to forest fires and improving firefighting efficiency. Additionally, it can mitigate safety risks for firefighters, presenting significant potential for application.

Forest firefighting robots need to possess the ability to navigate complex terrains and environments, including traversing ravines and thickets, climbing slopes, and clearing obstacles. They can be classified into three mobility modes: wheeled, tracked, and legged [62]. Among these, legged forest firefighting robots are developed based on bio-inspired design, incorporating the stability, coordination, and flexibility observed in the locomotion of crawling animals, thus holding crucial application prospects [63].

Analysis of the relevant literature [64–66] indicates that addressing forest fires with water-extinguishing methods may encounter challenges in terms of water sourcing. The use of chemical agents, such as dry powder for firefighting, may cause certain forest damage and add excessive payload to robots. Furthermore, forests often contain dense undergrowth, requiring obstacle clearance. Failure to clear obstacles in a timely manner could lead to missing the optimal firefighting window. Therefore, the purpose of this case study analysis was to overcome existing technological deficiencies and provide a forest firefighting robot solution that reduces environmental impact while enhancing firefighting efficiency.

An existing six-legged fire-fighting robot includes legs, a left arm, a right arm, a body, and a fire extinguisher, as shown in Figure 12. During firefighting operations, the robot has problems such as slow clearance and low efficiency of firefighting. In this section, the aforementioned model is applied to solve the problem of low working efficiency of this six-legged fire-fighting robot.

Figure 12. A six-legged fire-fighting robot.

Step 1: Identify problem functional elements based on root cause analysis.

1. The technical system of the product was decomposed, and a functional model was established, as shown in Figure 13.
2. A causal chain analysis is conducted to address the issue of the robot's low working efficiency, as shown in Figure 14. The root causes of the problem are obtained, and the relationship between the root cause and the problem functional element is identified. The overload and slow walking speed of mechanical legs correspond to the problem functional element of 'mechanical legs move chassis', the poor cutting performance of the saw blade corresponds to the problem functional element of 'saw blades cut weeds', and the low efficiency of fire extinguishing corresponds to the problem functional element of 'dry powder fire extinguishing'.

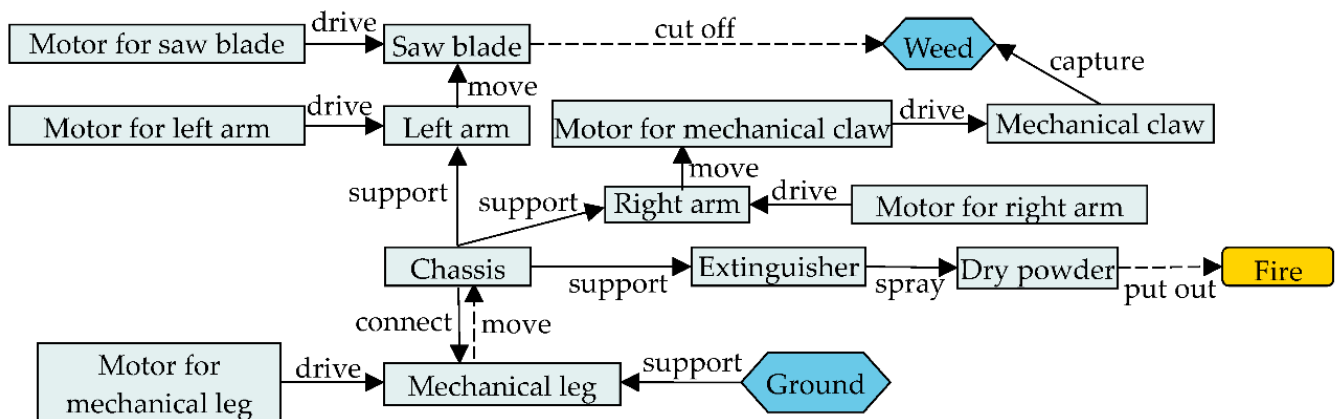

Figure 13. Functional model.

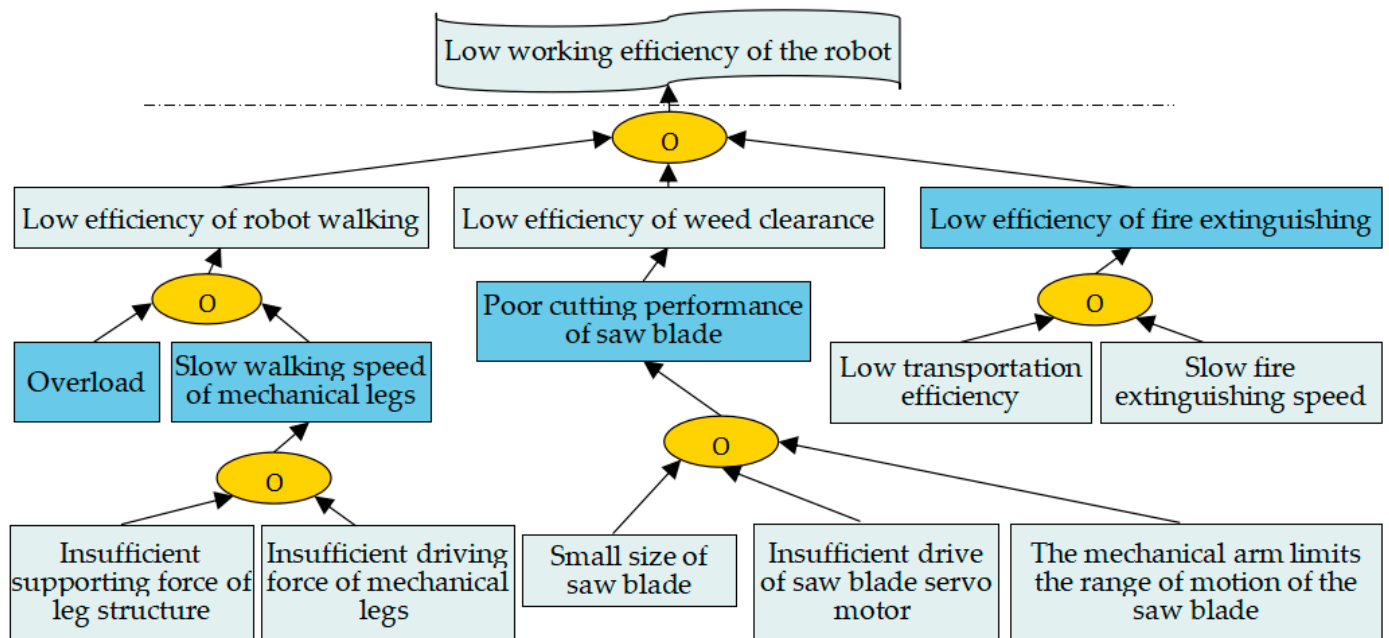

Figure 14. Causal chain analysis.

Step 2: Acquire similar biological prototypes.

1. All the functions completed by the above problem functional elements belong to the insufficient function. Search for these functions or similar functions in the Asknature biological knowledge base, and a search list of problem functional elements and biological prototypes is established, as shown in Table 8.
2. A list of similarity levels of the biological prototypes is built. Take the problem functional element of 'mechanical legs move chassis' as an example for analysis. First, analyze the similar elements of the similar functional elements, as shown in Table 9. Obtain the similar value of similar function elements about similar indexes, as shown in Table 10.

Table 8. Search list of problem function elements and biology prototypes.

Problem Functional Element	Function Search	Biological Prototype	Description	Biological Prototype	Description
Mechanical legs move chassis	Transfer, walking, moving on solid		The leg structure of a spider is highly flexible and adaptable, achieving precise bending movements through the coordinated action of hydraulics and muscles. The motion mechanism of spiders can be leveraged to enhance a robot's agility and adaptability.		Earthworms possess a soft, fluid-filled body that, through unique muscular movements and the coordinated interaction of internal fluids, enables them to crawl flexibly within the soil. Designers can draw inspiration from the biological traits of earthworms to enhance the flexibility and adaptability aspects of products, and apply these insights to the design process of robots intended for operation in confined and intricate environments.
			The cheetah's agile spine grants it exceptional speed and maneuverability, enabling rapid acceleration and pursuit of prey within a short span. For robot designs requiring swift and responsive actions, inspiration can be drawn from the cheetah's spinal structure and locomotion mechanism.		The snake's body moves in a motion resembling undulation, propelling itself forward through lateral undulating movements. This distinctive mode of locomotion enables the snake to navigate in confined spaces and adapt to various terrains and environments. Drawing inspiration from the snake's locomotion can provide valuable design insights for the agility and adaptability of products.
			The goat's hooves possess remarkable gripping ability, which stems from the unique structure and muscular control of the goat's feet, allowing it to maintain stability on uneven terrain. Drawing inspiration from this characteristic, industrial design can enhance product stability and control performance, enabling more reliable operation in specialized environments such as mountainous regions.		The salamander moves in a rolling manner across hilly terrains, using a rubber-like effect to mitigate and absorb impacts, safeguarding itself from jolts and vibrations. Applying this shock-absorption and protective mechanism of the salamander to industrial design can offer design inspiration for products that need to operate in vibrating or unstable environments.

Table 8. Cont.

Problem Functional Element	Function Search	Biological Prototype	Description	Biological Prototype	Description
		 Horse	The horse possesses robust bones and hard hooves, enabling it to swiftly gallop on solid ground. The horse's skeletal structure and the hardness of its hooves contribute to its exceptional running speed and stability. Incorporating these biological traits into industrial design can provide inspiration for products that require high-speed movement on hard surfaces. By drawing from the horse's sturdy skeletal nature and the durability of its hooves, industrial design can enhance product durability and stability, delivering improved performance.	 Terrestrial slug	The terrestrial slug secretes a unique viscoelastic mucus that allows it to crawl on various surfaces while maintaining stable adhesion. By drawing inspiration from this biological characteristic, industrial design can enhance product adhesion and stability, ensuring optimal performance in diverse environments. The application of this biological trait may contribute to improving a product's operational capability on a variety of terrains.
		 Ostrich	The legs of an ostrich exhibit excellent maneuverability due to mechanical principles, with relatively low joint torque loads. By drawing inspiration from the biological characteristics of ostrich legs, industrial design can optimize product mobility and stability, enabling outstanding performance across various motion scenarios.		

Table 8. Cont.

Problem Functional Element	Function Search	Biological Prototype	Description	Biological Prototype	Description
Saw blades cut weeds	Cut through solids, break down food		The radula of a limpet features cutting edges with incorporated magnetite crystals and silica. This unique biological structure enables the limpet to efficiently cut and digest food during feeding. The magnetite crystals provide the radula with substantial cutting power, while the silica enhances its abrasion resistance and corrosion resistance. Industrial design can optimize the cutting capacity and durability of cutting tools, allowing them to more effectively process various types of materials.		The teeth of the vampire bat are exceptionally sharp, suited for piercing the skin and blood vessels of hosts to obtain blood as a food source. Applying this feature to industrial design could inspire innovative solutions for penetration and cutting. This could enhance the performance of products in tasks involving penetration, cutting, and similar actions.
			The quetzal's beak, equipped with serrated cutting edges, is used for grasping and slicing food. Drawing inspiration from this biological characteristic could lead to more precise and efficient obstacle clearance.		The red oak weevil utilizes its distinctive cutting ability to slice and roll oak leaves into tubular structures. Applying this cutting capability in industrial design can inspire innovative material processing and component manufacturing methods.
			The lamprey possesses a specialized tongue structure capable of cutting through the scales and skin of fish. By drawing inspiration from this unique biological feature, improvements can be made to the performance of products in cutting and similar tasks.		The sawfish, with its unique sawing motion, is capable of slicing through or piercing prey. Its saw-toothed snout is not only used for sensing prey but also efficiently processing it. Applying the sawing motion of the sawfish to industrial design may offer new design inspirations for tasks like cutting and penetration. The biological characteristics of the sawfish can provide insights into the versatility and efficiency of products.

Table 8. Cont.

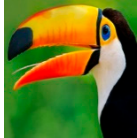

Problem Functional Element	Function Search	Biological Prototype	Description	Biological Prototype	Description
Dry powder fire extinguishing	Reduce temperature, isolate air, prevent oxidation		Herbivorous insects possess exceptional cutting ability in their mandibles, allowing them to effectively sever and process plant fibers. This biological feature offers new design insights for tasks such as handling fibrous materials and cutting grass. By incorporating this biological characteristic into industrial design, designers can explore more precise and efficient cutting solutions.		The platypus stores food in its cheek pouches and grinds and sorts insects and crustaceans between keratinized pads that replace teeth. Incorporating the mouth characteristics of the platypus into industrial design may offer new design insights for tasks such as material sorting and classification.
			The velvet mite possesses a blade-like mouthpart that effortlessly cuts through the chitinous layer of grasshoppers. By drawing inspiration from the blade-like mouthpart of the velvet mite, designers can explore more efficient and precise cutting solutions, thereby optimizing the processing of chitinous materials.		
			The Toco toucan regulates its body temperature by adjusting blood flow. Drawing inspiration from this biological feature, design a structure resembling the vascular network of a Toco toucan. This structure could regulate temperature by controlling the flow of water or liquids. Such a system could deliver cold water or firefighting agents to areas requiring temperature reduction, thereby achieving cooling effects through water utilization.		The cuticle of a wasp utilizes hair, thin layers, and branching tracheae to provide a cooling mechanism. Design a thin-layer structure similar to the wasp's cuticle, incorporating hydrogel or liquid cooling agents. This thin layer can be placed around a source of fire, achieving temperature reduction through gas circulation and heat conduction. Alternatively, inspired by the branching tracheae of wasps, a miniature channel network to conduct cool air through ventilation and airflow could be created.

Table 8. Cont.

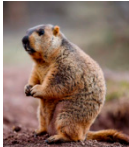

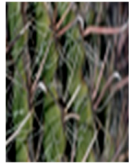

Problem Functional Element	Function Search	Biological Prototype	Description	Biological Prototype	Description
		 <p>Groundhog</p>	<p>Due to variations in cave entrance locations and shapes, groundhogs utilize changes in air pressure to harness wind energy for ventilation. Drawing inspiration from this biological feature, a firefighting system can be designed. By adjusting the aperture of the ventilation openings based on the fire's location and intensity, wind energy can be harnessed to expel hot air and introduce cooler air, thereby achieving temperature reduction. This system effectively utilizes air to cool down the environment.</p>	 <p>Bees</p>	<p>Bees cool their hive by collecting and dispersing water while fanning their wings to enhance evaporation. Drawing inspiration from this biological feature, a mist of water can be sprayed around the fire source to absorb heat through evaporation, effectively reducing the surrounding temperature. This approach achieves temperature reduction through the utilization of water.</p>
		 <p>Cactus</p>	<p>The ripple-like shape of a cactus creates a cool airflow, aiding in the dissipation of body heat. Applying this biological feature to industrial design, a heat dissipation structure resembling the ripple pattern of a cactus can be designed and used at fire scenes to achieve temperature reduction through air circulation.</p>	 <p>Squirrel</p>	<p>Squirrels use tree hollows or dig holes on the ground to store food, sealing the openings with mud or leaves. Drawing inspiration from this biological characteristic, a technique could be designed to use soil to isolate air and achieve firefighting by creating barriers around the fire scene.</p>
		 <p>Ticks</p>	<p>Ticks' mouths secrete a hydrophilic solution to absorb water vapor from the atmosphere. Leveraging this biological feature in industrial design, a system could be developed to absorb atmospheric water vapor and release it at a fire scene, achieving firefighting effects.</p>

$u_7(F_p, F_{b7})$	0	0.4	1	0.8	0	1	1	0	0	1
$u_8(F_p, F_{b8})$	0	0.4	1	0.8	0	1	1	0	0	0.5
$u_9(F_p, F_{b9})$	0	0.4	1	0.8	0	1	1	0	0	0.8
ω	0.125	0.25	0.125	0.125	0	0.125	0.125	0	0	0.125

Using the spider as an example, the functional similarity value between ‘mechanical legs move chassis’ and ‘spider’s legs move body’ is calculated, as shown in Equation (20).

$$Sim(u_i) = \sum_{j=1}^9 \omega_j Gra(k_j) = 0.7 \times 0.125 + 1 \times 0.25 + 1 \times 0.125 + 0.8 \times 0.125 + 1 \times 0.125 + 1 \times 0.125 + 0.8 \times 0.125 = 0.9125 \quad (20)$$

When the functional similarity value is ≥ 0.6 , the functions implemented by ‘mechanical legs move chassis’ and ‘spider’s legs move body’ are similar. A list of functional similarity values of the biological prototypes is then established, as shown in Table 11.

Table 11. List of functional similarity values of biology prototypes.

	Spider	Cheetah	Goat	Horse	Ostrich	Earthworm	Snake	Salamander	Terrestrial Slug
Functional similarity value	0.9125	0.9250	0.9250	0.9250	0.9250	0.6750	0.7000	0.6375	0.6750

Second, the behavior corresponding to ‘mechanical legs move chassis’ is ‘motor drives the mechanical leg.’ Calculate the behavioral similarity value between ‘motor drives the mechanical leg’ and the behavior corresponding to the realization of the function by the biological prototype. A list of behavioral similarity values of biological prototypes is established, as shown in Table 12.

Table 12. List of behavioral similarity values of biology prototypes.

	Spider	Cheetah	Goat	Horse	Ostrich	Earthworm	Snake	Salamander	Terrestrial Slug
Behavioral similarity value	0.7875	0.7875	0.8250	0.8250	0.7875	0.5250	0.5250	0.5875	0.5250

Finally, a list of similarity levels between the biological prototypes and the problem functional element ‘mechanical legs move chassis’ is established, as shown in Table 13. In the same way, obtain the similarity levels between the remaining two problem functional elements and their corresponding biological prototypes.

Table 13. List of similarity levels of biology prototypes.

Similarity Levels	Biology Prototype
Level I	Earthworm, Snake, Salamander, Terrestrial slug
Level III	Spider, Cheetah, Goat, Horse, Ostrich

Step 3: Generate integrated innovation ideas.

Based on the results of the root cause analysis, determine the problem functional elements of the product and the corresponding problem performances. An analysis list of problem functional elements is created, as shown in Table 14.

Table 14. Analysis list of problem function elements.

Problem Function Element	Functional Carrier	Action	Functional Object	Problem Performance Caused by the Functional Carrier	Problem Performance Caused by the Action	Problem Performance Caused by the Functional Object
Mechanical legs move chassis	Mechanical leg	Move	Chassis and its support structure	Insufficient support of leg structure	Insufficient drive of mechanical legs	Overload leads to slow movement speed
Saw blades cut weeds	Saw blade	Cut	Weeds	Insufficient cutting depth and cutting force of the saw blade	Narrow cutting range of saw blade	-
Dry powder fire extinguishing	Dry powder	Put out	Fire	-	Low transportation efficiency and slow fire extinguishing speed	-

For the problem functional element of ‘mechanical legs move chassis,’ the integrated idea is obtained by calculating the advantageous performance impact value of biological features. The process is as follows:

1. According to Table 4, score the advantageous performance caused by the functional carrier, action, or functional object of the biological prototype, as shown in Table 15. Assuming that the volumes of these biological prototypes are similar, the magnitude of the structural support force is judged according to the density of the functional object, and the greater the density of the functional object, the greater the performance value. The magnitude of the driving force is determined based on the variable characteristics of the functional carrier. The weight of the load is determined by the density of the functional object, and the smaller the density of the functional object, the higher the advantage performance value.
2. Analyze the biological features that the biological prototype possesses when exhibiting advantageous performance in implementing a similar function and establish a list of biological characteristics, as shown in Table 16.
3. Taking the salamander as an example, calculate the contribution of biological features using the AHP. First, calculate the contribution of biological features for the function carrier of the salamander. The steps are as follows:

Table 15. Advantageous performance values of biology prototypes.

Advantageous Performance		Influenced by the Functional Carrier: the Leg Structure Has Strong Support		Influenced by Action: the Mechanical Leg Has Strong Drive Power		Influenced by the Function Object: Light Load	
		Score P _e (S ₂)	Judgment Basis	Score P _e (F)	Judgment Basis	Score P _e (S ₁)	Judgment Basis
Similarity Level I	Salamander	5	Intrinsic attributes	7	Muscle and inertia	7	Intrinsic attributes
	Earthworm	3	Intrinsic attributes	5	Muscle and bristles	9	Intrinsic attributes
	Snake	3	Intrinsic attributes	5	Muscle and ventral scales	9	Intrinsic attributes
	Salamander	3	Intrinsic attributes	3	Muscle and mucus	9	Intrinsic attributes
Similarity Level III	Goat	7	Intrinsic attributes	7	Muscle and Legs	3	Intrinsic attributes
	Horse	9	Intrinsic attributes	7	Muscle and Legs	3	Intrinsic attributes
	Spider	7	Intrinsic attributes	9	Muscle and hydraulic, legs	5	Intrinsic attributes
	Cheetah	7	Intrinsic attributes	7	Muscle and Legs	3	Intrinsic attributes
	Ostrich	7	Intrinsic attributes	7	Muscle and Legs	3	Intrinsic attributes

Table 16. List of biological features.

Biological Feature		Features of the Functional Carrier			Features of the Action	Features of the Functional Object
		Morphology	Structural Distribution	Characteristic	Effect	Material
Similarity Level I	Salamander	Irregular	Whole body	Elasticity	Elasticity effect	Soft and low density
	Earthworm	S-shaped or hook-shaped bristles	Except for the first two segments, the rest are evenly distributed	Extensibility	Muscle peristaltic effect	Soft and segmented, low density
	Snake	Tile-like rectangular ventral scales	Closely arranged	Expand and close	Muscle peristaltic effect	Soft and low density
	Terrestrial slug	Arc-shaped	Abdomen	Flexibility	Viscoelastic effect	Soft and low density
Similarity Level III	Goat	Slender	Structural tandem	Strong grip of hooves.	Muscle contraction effect	Compact and high density
	Horse	Slender	Structural tandem	Hole-like structure to strengthen bones, hoof-like feet.	Muscle contraction effect	Compact and high density
	Spider	Slender	Structural tandem	Extensibility	Muscle contraction effect and hydraulic effect	Compact and low density
	Cheetah	Slender	Structural tandem	Extensibility	Muscle contraction effect	Compact and high density
	Ostrich	Slender	Structural tandem	Extensibility	Muscle contraction effect	Compact and high density

Step 1: Determine the composition of biological features. The set of biological features that contribute to the advantageous performance due to the functional carrier is denoted as X , where $X = \{\text{irregular shape, structure distributed throughout the body, elastic properties}\}$.

Step 2: Analyze the biological features and list the judgment matrix A .

$$A = \begin{bmatrix} 1 & 1/9 & 1/5 \\ 9 & 1 & 3 \\ 5 & 1/3 & 1 \end{bmatrix} \quad (21)$$

Step 3: Calculate the maximum eigenvalue of matrix A , $\lambda_{max} = 3.0291$. Normalize the obtained eigenvector G , resulting in the contribution value of the biological features, denoted as V , where $V = (0.0629, 0.6716, 0.2654)$.

The steps for consistency check are as follows:

- ① Calculate the consistency index (CI).

$$CI = \frac{\lambda_{max} - n}{n - 1} = \frac{3.0291 - 3}{3 - 1} = 0.0145 \quad (22)$$

- ② The table is checked to obtain the random index (RI).

$$RI = 0.52 \quad (23)$$

- ③ Calculate the consistency ratio (CR).

$$CR = \frac{CI}{RI} = \frac{0.0145}{0.52} = 0.0279 \quad (24)$$

When $CR < 0.1$, it is considered that the consistency of the judgment matrix is acceptable.

As the number of biological features contributing to the advantageous performance induced by both the functional action and the functional object of the salamander is 1, the contribution value of the features is therefore 1. In a similar way, calculate the contribution of features for other biological prototypes. Build a score table of the contribution of biological features for the problem functional element, ‘mechanical legs move chassis,’ as shown in Table 17.

4. Calculate the advantageous performance impact value of the biological features, as shown in Table 18.

Table 17. Score table of contribution of biological features for ‘mechanical legs move chassis’.

Biological Feature		Features of the Functional Carrier			Features of the Action	Features of the Functional Object
		Morphology	Structural Distribution	Characteristic	Effect	Material
Similarity Level I	Salamander	0.0629	0.6716	0.2654	1	1
	Earthworm	0.5820	0.3667	0.0513	1	1
	Snake	0.5969	0.3458	0.0572	1	1
	Terrestrial slug	0.3458	0.5969	0.0572	1	1
Similarity Level III	Goat	0.1692	0.3874	0.4434	1	1
	Horse	0.2599	0.3275	0.4126	1	1
	Spider	0.2926	0.6406	0.0668	1	1
	Cheetah	0.3458	0.5969	0.0572	1	1
	Ostrich	0.6716	0.2654	0.0629	1	1

Table 18. Score of advantageous performance impact value for ‘mechanical legs move chassis’.

Biological Feature		Features of the Functional Carrier			Features of the Action	Features of the Functional Object
		Morphology	Structural Distribution	Characteristic	Effect	Material
Similarity Level I	Salamander	0.3145	3.3580	1.3270	3	7
	Earthworm	1.7460	1.1001	0.1539	5	9
	Snake	1.7907	1.0374	0.1716	5	9
	Terrestrial slug	1.0374	1.7907	0.1716	3	9
Similarity Level III	Goat	1.1844	2.7118	3.1038	7	3
	Horse	2.3391	2.9475	3.7134	7	3
	Spider	2.0482	4.4842	0.4676	9	5
	Cheetah	2.4206	4.1783	0.4004	7	3
	Ostrich	4.7012	1.8578	0.4403	7	3

Within biological prototypes with the same effect, select and integrate the features from the prototypes with the highest advantageous performance impact value in each category into the product. A total of four integrated ideas are obtained.

In a similar way, the integrated ideas of the problem functional element of ‘saw blades cut weeds’ and the problem functional element of ‘dry powder fire extinguishing’ can be obtained. A morphological matrix of multiple problem functional elements is established,

as shown in Table 19. The integrated idea with the highest value of practical degree parameter in each problem function element is selected to solve the problem.

Table 19. Analysis list of problem function elements.

Problem Functional Element	Integrated Idea	Integrated Idea 1	Integrated Idea 2	Integrated Idea 3	Integrated Idea 4
Mechanical legs move chassis		Integration: the slender morphology of ostrich legs; the structural distribution of spider legs in series; hole-like structure to strengthen bones, hoof-like feet in horse legs; muscle contraction effect and hydraulic effect of spider legs; materials with low density in body.	Integration: tile-like rectangular ventral scales morphology of snakes; bristle evenly distributed structural distribution of earthworms; expand and close characteristics of snake ventral scales; muscle peristaltic effect of earthworms and snakes; materials with low density in snake or earthworm bodies.	Integration: irregular morphology, structural distribution throughout the body, and elastic characteristics of salamander muscles; elasticity effect of muscles; materials with low density in the body.	Integration: features of terrestrial slugs: arc-shaped morphology of muscles, structural distribution in the abdomen, flexibility; viscoelastic effect; materials with low density in the body.
Saw blades cut weeds		Integration: the quetzal's beak with serrated cutting edges, the lamprey's teeth with evenly distributed structures, herbivorous insects with mouthparts uniformly distributed, and vampire bats with mouthparts exhibiting the behavior of opening and closing.	Integration: the platypus exhibits a flat and wide morphology in its bill, with a symmetrical structural distribution. The bill has raised ridges and possesses grinding characteristics. The platypus also demonstrates the behavior of moving the keratin layer between the upper and lower jaws.	Integration: the nose of sawfish is long and flat, with serrated protrusion on both sides, and the structure distribution is evenly distributed on both sides. The sharp nature of weevils' mouthparts, the behavior of a limpet moving its tongue, a weevil moving its mouthparts, or a sawfish swinging its serrated nose.	
Dry powder fire extinguishing		Integration: air-cooling effect	Integration: water-cooling effect	Integration: solid heat transfer cooling effect	Integration: soil fire-extinguishing effect

Step 4: Select integrated innovation idea based on P_{di} .

For the problem functional element of 'mechanical legs move chassis,' the value of P_{di} of the integrated idea is calculated by Equation (6). The calculation process is shown in Table 20. The integrated idea 1, which has the highest value of P_{di} , was selected as the final solution.

Table 20. Calculation process of P_{di} for 'mechanical legs move chassis'.

Mechanical Legs Move Chassis	P_{oi}	C_{di}	P_{di}	Sort
Integrated idea 1	26.8988	5	5.3798	1
Integrated idea 2	17.0624	7	2.4375	2
Integrated idea 3	14.9995	9	1.6666	4
Integrated idea 4	14.9997	7	2.1428	3

In a similar way, for the problem functional element of 'saw blades cut weeds,' integrated idea 3 was selected as the final solution. For the problem functional element of 'dry powder fire extinguishing,' integrated idea 4 was selected as the final solution.

Step 5: Obtain the principal solution based on biological feature mapping.

1. Solve the problem functional element of ‘mechanical legs move chassis’.

This integrated innovation idea includes the integration of morphology, structural distribution, characteristics, effects, and materials. Regarding effects, principal solutions are obtained based on the E_b - E_t - S_e mapping. For morphology, structural distribution, characteristics, and materials, principal solutions are obtained based on the S_b - S_e mapping.

(1) Acquire the principal solution based on E_b - E_t - S_e mapping.

Inspiration. The underside of the femur, patella, and tibia-metatarsal joints of the spider is filled with hemlymphatic fluid, which fills the spaces between muscle fibers. This fluid exerts pressure on the rippled structure, causing the legs to lengthen. Inspired by the muscle contraction effect and hydraulic effect, designers can draw insights for applying these principles in the engineering field, resulting in structures such as excavator mechanical arms, carousel lifting devices, tricycle self-dumping buckets, and hydraulic lifting platforms.

Search. Integrating the muscle contraction effect and hydraulic effect of spider legs, the movement of the mechanical leg applied the muscle contraction effect. By expanding synonyms, near synonyms, or related words for hydraulic effect, movement function, and mechanical leg, the search formula is TAC: (“walking” OR “walking mechanism” OR “walking device” OR “walking drive”) AND TAC: (“hydraulic” OR “hydraulic type” OR “hydraulic device” OR “hydraulic drive” OR “hydraulic mechanism”) AND TAC: (“mechanical leg” OR “Leg mechanism” OR “Leg device”). The patents were clustered and screened based on experience, and the resulting patents are shown in Table 21.

Based on experience, all the structures obtained above were analyzed, and three engineering structures were selected: hydraulic auxiliary series mechanical leg with energy storage device, as shown in Z2. Hydraulic cylinders were connected in parallel as mechanical legs, and the hydraulic cylinder was equipped with an energy storage device, as shown in Z3. Hydraulic cylinders were connected in series as a mechanical leg, and the hydraulic cylinder was equipped with an energy storage device, as shown in Z4.

(2) Acquire principal solution based on S_b - S_e mapping.

For morphology, the mechanical leg already has the feature of the slender shape of the ostrich leg, and no improvement was needed. For structural distribution, the mechanical leg already has the feature of the spider leg in series, and no improvement was needed. For structure and foot material, the hole structure of the horse was applied to the design of the mechanical leg. A high-carbon alloy steel material with high hardness was searched for in the engineering field, and the material was replaced with the raw material used for the foot of the mechanical leg, with nylon on the outside and high-carbon alloy steel on the inside. For the body, in order to reduce the load, low-density aluminum alloy material was used.

2. Solve the problem functional element of ‘saw blades cut weeds’.

This integrated innovation idea includes the integration of morphology, structural distribution, characteristics, and behavior. For morphology, structural distribution, and characteristics, based on the principal solution of S_b - S_e mapping acquisition, an electric chainsaw can be obtained.

Regarding behaviors, principal solutions are obtained based on the B_b - B_e - S_e mapping. Integrate the behavior of the limpet moving its radula, the weevil moving its mouthpart, and the sawfish swinging its serrated nose with the product. For the product, it involves integrating the behavior of a translating chainsaw mechanism to achieve weed cutting. Establish a behavioral chain related to weed cutting functionality, as shown in Figure 15.

Table 21. Patent list for solving the problem functional element of ‘mechanical legs move chassis’.

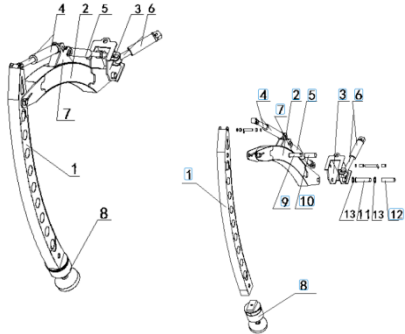

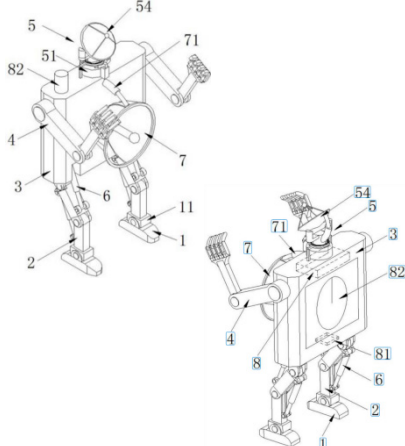

Serial Number	Title	Abstract	Figure
Z1	A robot leg [67] CN204150141U	<p>This utility model patent discloses a robot leg, aiming to address the issues in existing multi-legged robot legs, such as their large volume and weight, limited load-bearing capacity, low walking efficiency, and excessive noise during movement. It includes the first supporting arm 1, the second supporting arm 2, a base 3, the first hydraulic cylinder 4, the second hydraulic cylinder 5, the third hydraulic cylinder 6, etc. Furthermore, this utility model patent also provides a robot leg with a bushing connection. Hydraulic cylinder 4 drives the first support arm 1 to rotate around the second support arm 2. Based on the gait planning of quadruped robots, this utility model patent employs an entirely new design structure that effectively achieves movements like forward, backward, turning, climbing, and obstacle crossing.</p>	
Z2	An industrial robot and its industrial robot obstacle avoidance system [68] CN113370207A	<p>This invention belongs to the field of industrial robotics, particularly an industrial robot and its industrial robot obstacle avoidance system. It includes foot 1, mechanical leg 2, body 3, mechanical arm 4, and a head 5 for scanning in all directions. The travel of mechanical leg 2 is achieved by the work of hydraulic cylinder 6. The top of the foot is hinged to the bottom of the mechanical leg to achieve walking. The top of the mechanical leg is hinged to the bottom of the body to achieve the robot's standing up or sitting down. This invention fully utilizes the characteristics of radar scanning imaging to display the contour shape of obstacles in front of the robot through radar scanning. As a result, the area outside the contour shape of obstacles is the accessible area for the robot to walk without obstacles. It can not only target solid obstacles but also perform radar detection on uneven ground or uneven terrain, enabling the robot to adapt to material handling actions in different environments and eliminating the safety hazards of manually handling flammable and explosive materials.</p>	

Table 21. Cont.

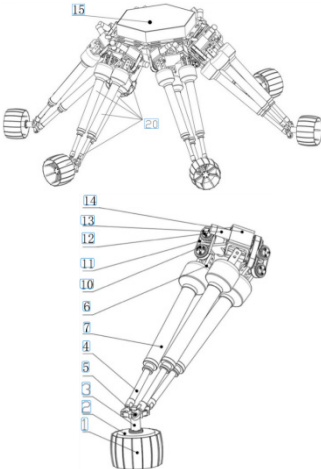

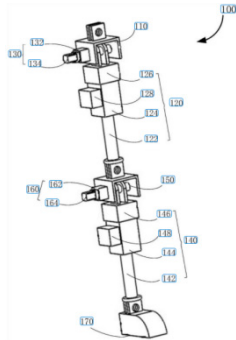

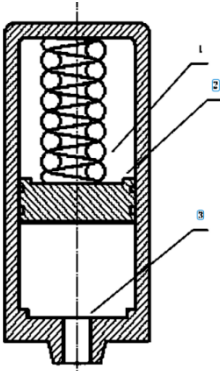

Serial Number	Title	Abstract	Figure
Z3	Parallel structure wheel-legged robot based on UPS [69] CN111976859B	<p>This invention provides a parallel structure wheeled-leg mobile robot based on UPS, comprising wheels 1, a support carrier 15, and six mechanical leg components 20. One end of each of the six mechanical leg components is evenly distributed along the circumferential side of the support carrier. The wheels are mounted on the other end of the mechanical leg components. Mechanical leg components are driven by hydraulic cylinders to achieve travel. The robot includes both a wheeled motion mode and a legged motion mode, capable of switching between them based on different scenarios. In the wheeled motion mode, the wheels' circumferential surface contacts the ground, and they move using rolling motion. In the legged motion mode, the wheels' lateral surface contacts the ground, and the robot moves using legged walking motion. By adopting the 3UPS parallel six-degree-of-freedom mechanical arm structure, this invention exhibits high flexibility and significant load-bearing capacity. It can carry more sensors to execute more complex probing tasks. The pose of the robot's foot end relative to the frame corresponds to motion inputs and can be uniquely determined through calculations, ensuring precise control and strong stability.</p>	
Z4	Walkable robots [70] CN114684294A	<p>A walkable robot, comprising a body and a walking mechanism coupled to the body to support it. The walking mechanism includes the first leg mechanism 100 and the second leg mechanism. The first leg mechanism is operatively coupled to the body via the first main joint 110 and can rotate relative to the body around the first main joint. The second leg mechanism is operatively coupled to the body via the second main joint and can rotate relative to the body around the second main joint. Both the first leg mechanism and the second leg mechanism comprise the upper support component 120, main joint drive component 130, lower support component 140, intermediate joint drive component 160, contact sensor 170, and a motion controller.</p> <p>In the upper support component 120, hydraulic cylinder 124 is capable of generating an upper driving force extending along its length.</p>	

Table 21. Cont.

Serial Number	Title	Abstract	Figure
Z5	An integrated hydraulic drive with an accumulator [71] CN108825565A	<p>The present invention discloses an integrated hydraulic driving device with an energy storage unit, aiming to address the issues in existing robots where the lack of leg energy storage components leads to energy wastage and potential impact vibrations during movement, resulting in seal element detachment and hindering the normal locomotion of multi-legged robots. When applied to joint driving of multi-legged robots, this invention can convert the kinetic and gravitational potential energy of leg mechanisms into hydraulic energy for storage, achieving energy recovery and extending the walking range of multi-legged robots, thus enhancing their applicability. Additionally, this invention not only provides energy for the next leg lifting action but also serves as a cushioning and vibration absorption mechanism, effectively reducing impact loads from the ground. The present invention can effectively buffer the effects, realize energy conversion efficiently, and minimize the impact of shock vibrations on seal components. This invention is user-friendly, easy to maintain, and holds significant importance for the long-distance, low-energy operation of multi-legged robots.</p>	

Figure 15. Behavior chains related to the function of cutting weeds.

Perform behavior sharing and establish a behavior-component matrix, as shown in Table 22. The mechanical arm can be used as the moving mechanism to achieve the translation of the chainsaw. Therefore, a solution combining the mechanical arm and the chainsaw is obtained. However, using the mechanical arm directly would complicate the control and operation.

Table 22. Behavior-component matrix.

Behavior \ Component	C ₁ : Chainsaw Motor	C ₂ : Chainsaw	C ₃ : Mechanical Arm
B ₁ : Mechanical arm moves chainsaw to designated position	0	1	1
B ₂ : Chainsaw motor driven chainsaw	1	1	0

Perform behavior addition by integrating the behavior of the moving mechanism with the chainsaw into the product. The specific steps are as follows:

① Establish the behavior feature model of the moving mechanism with the chainsaw, as shown in Figure 16. When the moving mechanism translates the chainsaw, the chainsaw itself rotates to cut branches and weeds.

Figure 16. Behavior characteristics model of translating the chainsaw with the moving mechanism.

② Create a behavior correlation matrix, as shown in Figure 17. The receiving state of chainsaw B₂, driven by the chainsaw motor, is the same as the pre-acceptance state of the moving mechanism with the chainsaw B_a. Therefore, B_a is placed after B₂. Make appropriate adjustments to obtain an improved behavior chain, as shown in Figure 18.

	B _a	B ₁			B _a	B ₂
B _a	/	0		B _a	/	0
B ₁	0	/		B ₂	1	/

Figure 17. Behavior incidence matrix of translating chain saws with moving mechanism.

③ Determine the compatibility of behaviors. The behavior of the translating chainsaw mechanism converts electrical energy into mechanical energy. The mechanical energy input for weed cutting comes from two sources: the chainsaw motor and the translating mechanism. Increasing the behavior of the translating mechanism in moving the chainsaw reduces the proportion of energy output from the previous behavior, resulting in an increase in mechanical efficiency for cutting weeds. Since no changes are made to the substance

or signal, the behavior of the translating chainsaw mechanism is compatible with the previous behavior.

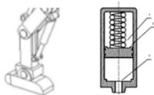

④ Search for components in the engineering field to implement this behavior. The movement of the limpet's radula, the weevil's mouthparts, or the sawfish's swinging saw-like nose is achieved through muscle contraction. Therefore, the driving device for the translating mechanism can be an electric motor or a hydraulic motor. Furthermore, options for the translating mechanism include crank-slider mechanisms, cam mechanisms, gear-rack mechanisms, sliding table hydraulic cylinders, and ball screw mechanisms.

⑤ Component compatibility assessment. The crank-slider mechanism, cam mechanism, gear-rack mechanism, sliding table hydraulic cylinder, and ball screw mechanism are the components to be added, which have a connection relationship with the robotic arm and the chainsaw motor, satisfying component compatibility. These components will be securely attached to the end of the robotic arm, while the chainsaw motor will be positioned on the slider, connecting rod, rack, or sliding table structure of these components.

Step 6: Acquire preliminary solution.

Summarize the structures obtained from the aforementioned three problem functional elements and establish a morphological matrix, as shown in Table 23.

Table 23. Morphological matrix.

Function	Structure				
Mechanical legs move chassis	 <p>Hydraulic cylinder assisted serial mechanical leg + energy storage device</p>	 <p>Parallel hydraulic cylinder as a mechanical leg + energy storage device</p>	 <p>Serial hydraulic cylinder as a mechanical leg + energy storage device</p>		
Saw blades cut weeds	 <p>Crank-slider mechanism + electric chainsaw</p>	 <p>Cam mechanism + electric chainsaw</p>	 <p>Rack and pinion mechanism + electric chainsaw</p>	 <p>Slider hydraulic cylinder + electric chainsaw</p>	 <p>Ball screw + electric chainsaw</p>
Soil-crushing	 <p>Mechanical claw</p>	 <p>Cutting turntable-Crusher roller</p>	 <p>Two screw conveyors rotating in opposite directions</p>	 <p>Drum for raising soil + gear for breaking soil</p>	
Soil-shoveling	 <p>Bucket</p>	 <p>Excavator arm + Mechanical claw</p>	 <p>Shovel</p>	 <p>Fire plow</p>	
Soil-filtering	 <p>Filter mesh</p>	 <p>Sieve bucket</p>			
Soil-conveying	 <p>Screw conveyor</p>	 <p>Excavator arm</p>	 <p>Conveyor belt</p>		
Soil-lifting	 <p>Rotating soil throwing mechanism</p>	 <p>Fan</p>	 <p>Air compressor</p>	 <p>Drum for raising soil + plate for raising soil</p>	

Figure 18. Improved behavior chain.

Based on the compatibility of various structures, five initial schemes with higher feasibility were obtained through matching, as shown in Table 24.

Table 24. Initial schemes.

Function	Scheme 1	Scheme 2	Scheme 3	Scheme 4	Scheme 5
Mechanical legs move chassis	Hydraulic cylinder assisted serial mechanical leg + energy storage device	Hydraulic cylinder assisted serial mechanical leg + energy storage device	Hydraulic cylinder assisted serial mechanical leg + energy storage device	Hydraulic cylinder assisted serial mechanical leg + energy storage device	Hydraulic cylinder assisted serial mechanical leg + energy storage device
Saw blades cut weeds	Crank-slider mechanism + electric chainsaw	Cam mechanism + electric chainsaw	Rack and pinion mechanism + electric chainsaw	Slider hydraulic cylinder + electric chainsaw	Ball screw + electric chainsaw
Crush soil	Mechanical claw	Cutting turntable + crusher roller	Cutting turntable + crusher roller	Cutting turntable + crusher roller	Drum for raising soil + gear for breaking soil
Shovel soil	Excavator arm + mechanical claw	Shovel	Excavator arm + mechanical claw	Bucket	-
Filter soil	Filter mesh	-	Sieve bucket	Filter mesh	-
Convey soil	Conveyor belt	Excavator arm	-	Screw conveyor	Excavator arm
Lift soil	Fan	-	Rotating soil throwing mechanism	Air compressor	Drum for raising soil + plate for raising soil

Use the method of ‘Entropy Weight Method-Grey Relational Analysis’ to evaluate the five preliminary schemes. Combined with the needs of users and the development strategies of technicians, five evaluation indicators were proposed: fire extinguishing efficiency, economy, novelty, ease of manufacture, and space occupancy rate. Experts were invited to score the five indicators (full score of 10 points, which are positive integers) to obtain the score list, as shown in Table 25.

Table 25. Score list.

	Fire Extinguishing Efficiency	Economy	Novelty	Ease of Manufacturing	Space Occupancy Rate
Scheme 1	7	5	7	6	7
Scheme 2	8	9	6	9	7
Scheme 3	6	7	8	8	7
Scheme 4	9	6	9	6	9
Scheme 5	5	8	5	7	7

Step 7: Program evaluation.

(1) Determine the weights.

The weights of the evaluation indicators were calculated according to the entropy weight method. The specific calculation steps are as follows:

1. Construct the evaluation index matrix. There are five evaluation indicators and five evaluation objects in the evaluation system. The evaluation index matrix X is constructed based on the score sheet.

$$X = \begin{bmatrix} 7 & 8 & 6 & 9 & 5 \\ 5 & 9 & 7 & 6 & 8 \\ 7 & 6 & 8 & 9 & 5 \\ 6 & 9 & 8 & 6 & 7 \\ 7 & 7 & 7 & 9 & 7 \end{bmatrix}$$

2. Calculate the weight p_{ij} of the j -th evaluation object under the i -th evaluation indicator according to Equation (8) ($i = 1,2,3,4,5; j = 1,2,3,4,5$), forming the matrix P .

$$P = \begin{bmatrix} 0.2000 & 0.2286 & 0.1714 & 0.2571 & 0.1429 \\ 0.1429 & 0.2571 & 0.2000 & 0.1714 & 0.2286 \\ 0.2000 & 0.1714 & 0.2286 & 0.2571 & 0.1429 \\ 0.1667 & 0.2500 & 0.2222 & 0.1667 & 0.1944 \\ 0.1892 & 0.1892 & 0.1892 & 0.2432 & 0.1892 \end{bmatrix}$$

3. Calculate the entropy value of each indicator e_i ($i = 1,2,3,4,5$) according to Equation (9), and form the matrix E .

$$E = [0.9871 \quad 0.9871 \quad 0.9871 \quad 0.9919 \quad 0.9965]$$

4. Calculate the information entropy redundancy d_i ($i = 1,2,3,4,5$) of each indicator according to Equation (10), and calculate the weight ω_i ($i = 1,2,3,4,5$) of each indicator according to Equation (11) to form the matrix W .

$$W = [0.2565 \quad 0.2565 \quad 0.2565 \quad 0.1610 \quad 0.0695]$$

(2) Evaluation of schemes.

1. Construct the initial decision matrix Y , which involves five evaluation indicators and five evaluation objects.

$$Y = \begin{bmatrix} 7 & 5 & 7 & 6 & 7 \\ 8 & 9 & 6 & 9 & 7 \\ 6 & 7 & 8 & 8 & 7 \\ 9 & 6 & 9 & 6 & 9 \\ 5 & 8 & 5 & 7 & 7 \end{bmatrix}$$

2. Standardization of the data. Among these evaluation criteria, the largest data value is considered the best, and y'_{ij} was obtained according to Equation (13), which constitutes the standardization matrix Y' , while $y_o'(j)$ was obtained according to Equation (15), $y_o'(1) = y_o'(2) = y_o'(3) = y_o'(4) = y_o'(5) = 1.0000$.

$$Y' = \begin{bmatrix} 0.5000 & 0.0000 & 0.5000 & 0.0000 & 0.0000 \\ 0.7500 & 1.0000 & 0.2500 & 1.0000 & 0.0000 \\ 0.2500 & 0.5000 & 0.7500 & 0.6667 & 0.0000 \\ 1.0000 & 0.2500 & 1.0000 & 0.0000 & 1.0000 \\ 0.0000 & 0.7500 & 0.0000 & 0.3333 & 0.0000 \end{bmatrix}$$

3. Calculate the difference between each normalized term and its reference value and build the difference matrix Δ .

$$\Delta = \begin{bmatrix} 0.5000 & 1.0000 & 0.5000 & 1.0000 & 1.0000 \\ 0.2500 & 0.0000 & 0.7500 & 0.0000 & 1.0000 \\ 0.7500 & 0.5000 & 0.2500 & 0.3333 & 1.0000 \\ 0.0000 & 0.7500 & 0.0000 & 0.0000 & 0.0000 \\ 1.0000 & 0.2500 & 1.0000 & 0.6667 & 1.0000 \end{bmatrix}$$

4. Calculate the gray correlation coefficient $r_{oi}(j)$ for each item to form the matrix R.

$$R = \begin{bmatrix} 0.5000 & 0.3333 & 0.5000 & 0.3333 & 0.0000 \\ 0.6667 & 1.0000 & 0.4000 & 1.0000 & 0.0000 \\ 0.4000 & 0.5000 & 0.6667 & 0.6000 & 0.0000 \\ 1.0000 & 0.4000 & 1.0000 & 1.0000 & 1.0000 \\ 0.3333 & 0.6667 & 0.3333 & 0.4286 & 0.0000 \end{bmatrix}$$

5. Calculate the gray correlation Γ_{oi} . The gray correlation values are shown in Table 26.

Table 26. Grey correlation degree value.

	Scheme 1	Scheme 2	Scheme 3	Scheme 4	Scheme 5
Correlation value	5	8	5	7	7

Therefore, scheme 4 has the largest grey correlation degree value, and scheme 4 is the optimal scheme.

Step 8: Problem analysis and solution.

Improvements were made to the six-legged firefighting robot according to scheme 4, as illustrated in Figure 19. The upper segments of the mechanical legs, akin to ‘thighs’ in human anatomy, employed tandem mechanical legs aided by hydraulics, with accumulators featured in the hydraulic devices. The lower segments of the mechanical legs, comparable to ‘calves’ remained unchanged, being driven by motors. The robot’s left and right ‘arms’ were replaced by mechanical legs. The hydraulic cylinders for the sliding platform and the electric chainsaw were situated on the lower segments of the four mechanical legs that were oriented toward the front and back, respectively. Furthermore, the electric chainsaw was affixed to the sliding platform. The rotation of the chainsaw grinds down obstacles, while the outward sliding of the hydraulic cylinder of the sliding platform enables the chainsaw to cut through obstacles. Cutting turntables and soil-crushing rollers were installed on the lower segments of the two middle mechanical legs, with the rotation of the cutting turntable driving the soil-crushing rollers to break down the soil. In addition, a conveyor shovel with a screen was incorporated. The conveyor shovel was placed on the upper segments of the two middle mechanical legs, with a bucket hinged to the rear of the conveyor shovel for shoveling soil. The conveyor shovel with the screen facilitates soil transport and filtering. A screw conveyor was integrated into the body of the robot to transport soil, and an air compressor, located above the screw conveyor, was used to elevate the soil.

Figure 19. Improvement process diagram of the firefighting robot.

By further adjusting the structure of the robot, the initial product concept structure was achieved, as depicted in Figure 20. The robot comprised a box, a six-legged walking mechanism, two soil extraction mechanisms, two soil-lifting mechanisms, four obstacle-clearing mechanisms, and four vertical moving support mechanisms.

Figure 20. Improvement process diagram of the firefighting robot.

When building the conceptual structure, the obstacle-clearing mechanism was positioned at the lower segment of the mechanical leg to enhance the range of obstacle clearance, but this interfered with the robot's mobility. To solve this problem, the TRIZ theory was applied to resolve the technical conflict. A solution was found: a platform flip hydraulic cylinder was installed under the obstacle-clearing support platform, and a rotating platform was set up between the sliding platform and the chainsaw motor, as shown in Figure 21. After the obstacle was cleared, the hydraulic cylinder of the sliding platform contracted, moving the sliding platform to its inner limit position. The rotating platform then pivoted, causing the chainsaw motor and chainsaw to rotate 90° clockwise. Subsequently, the platform flip hydraulic cylinder extended, causing the obstacle-clearing support platform to tilt inward, thus retracting the obstacle-clearing mechanism. After incorporating the platform flip hydraulic cylinder and the rotating platform, the final product concept structure was obtained, i.e., a soil-lifting six-legged firefighting robot.

Figure 21. Improvement process diagram of the firefighting robot.

5. Discussion and Conclusions

Integrated innovation aids in enhancing an enterprise's independent innovative ability, helping it to hold a dominant position in the market. Multi-biological knowledge can spark innovative thoughts among designers, providing them with fresh inspirations. The key to realizing product-integrated innovation lies in how to generate integrated innovation ideas based on multi-biological knowledge and how to construct product conceptual structures through the transfer and integration of cross-domain biological knowledge. Based on the BID process, this study explored the integrated innovation mechanism based on biological

inspiration. It proposed a method of generating integrated innovation ideas based on biological inspiration, as well as a method of establishing integrated innovation concept structure based on biological feature mapping, ultimately presenting a process model of product-integrated innovation design based on biological inspiration. This process effectively guides designers in achieving integrated innovation through multi-biological knowledge inspiration. The method proposed in this paper offers a novel approach to industrial design.

The objective of industrial design is to enhance the quality, functionality, and usability of products through creative and innovative design. It focuses on addressing potential issues that products may encounter during practical use, thereby elevating user experience and fulfilling their needs. Applying the bio-inspired integrated innovation design method to industrial design introduces a distinctive avenue for tackling complex problems and fostering innovative solutions. By integrating multi-biological features, designers can conceive products with inherent high efficiency and quality, enabling these products to adapt to various environments and enhance their versatility. Simultaneously, this approach also introduces new perspectives for managing the product life cycle within industrial design. With continuous advancements in biological sciences and engineering technologies, the potential of this innovative approach will persistently expand, spanning across various industries, thus presenting more opportunities and challenges to the field of industrial design.

This study addressed existing product problems by analyzing the relationship between root cause and problem performance. It identified problem functional elements based on root cause analysis and obtained similar biological prototypes through function search and similarity analysis. Borrowing from the biological coupling analysis method, biological features with the highest advantageous performance impact value in each category were selected and integrated with the product to solve the problem functional element. A method of generating integrated innovation ideas based on biological inspiration was proposed. This method provides the core idea for constructing an integrated innovation conceptual structure. This study, approaches from the angles of biological effects, biological behavior, and biological structure, obtaining principal solutions based on E_b - E_t - S_e mapping, B_b - B_e - S_e mapping, and S_b - S_e mapping. On this basis, it used a morphological matrix to generate initial schemes, performed scheme evaluations to form conceptual structures, and put forward a method of establishing integrated innovation concept structure based on biological feature mapping. This method effectively guides designers in conceptual design for integrated innovation ideas, forming conceptual structures. Lastly, in combination with TRIZ theory, a process model of product-integrated innovation design based on biological inspiration was established. Applying this process model to the innovative design of a six-legged firefighting robot verified the feasibility of the proposed method.

The innovation points of the proposed approach mainly encompass two aspects. On one hand, by discerning the similarities between biological functions and product functions, biological prototypes were obtained. Drawing inspiration from the biological coupling analysis approach, biological performance was analyzed. Multiple biological prototypes that exhibited advantageous features while accomplishing identical or similar biological functions were integrated, addressing individual problem functional elements. This contrasts with the conventional approach of utilizing a single biological prototype to solve individual problem functional elements. On the other hand, by employing three mapping techniques, the principal solutions were extracted, allowing the transfer of biological features into product design through concrete methods.

Despite the advantages of the new design approach, there are some limitations in this study.

- This study established an attribute-based advantageous performance value judgement index to evaluate the biological prototype, but the evaluation needs to rely on the designer's own experience, and there is a certain degree of subjectivity.

- In the process of obtaining similar biological prototypes, only the Asknature biological knowledge base was used as a search source, resulting in a single source of retrieval and certain limitations.
- In the process of obtaining principal solutions based on E_b - E_t - S_e mapping, detailed guidance on the process of mapping for inspiration is lacking.
