Supplementary Materials

Once the criteria for each section are validated, the information is extracted in tabular form, documenting in linear form each of the formulations and results obtained, with their respective units and identification fields. These are summarized in the following structure in Table S1 (It should be noted that all the columns of units respective to each property were suppressed to focus only on the properties obtained):

Table S1. Structure of data extraction in table form.

Table S2 represents Pearson correlation with mechanical properties by raw data, should be possible to observe which components promote the respective property according to the subset of the extracted data, but how sparse data the metrics is not useful for indicating the relationship of the components.

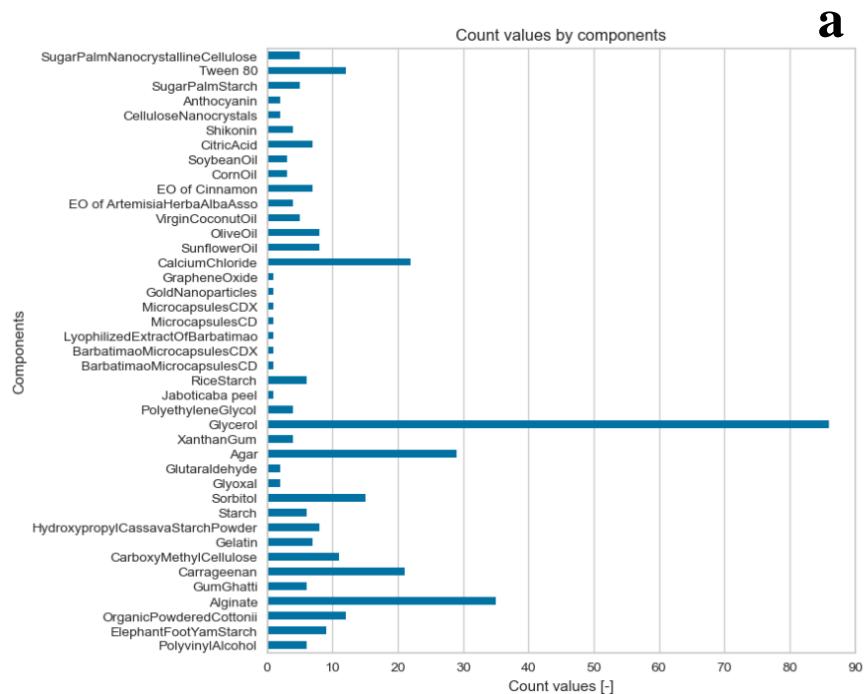

Table S2. Pearson correlation for raw data with respect to mechanical properties.

Figure S1 shows the number of values for each of the components (A) with the standard deviation (B). It is observed that there is a high variation between the amount of one component and another, as well as the variation of the component values. This is relevant because it implies that there are characteristics that offer more information than others for the model.

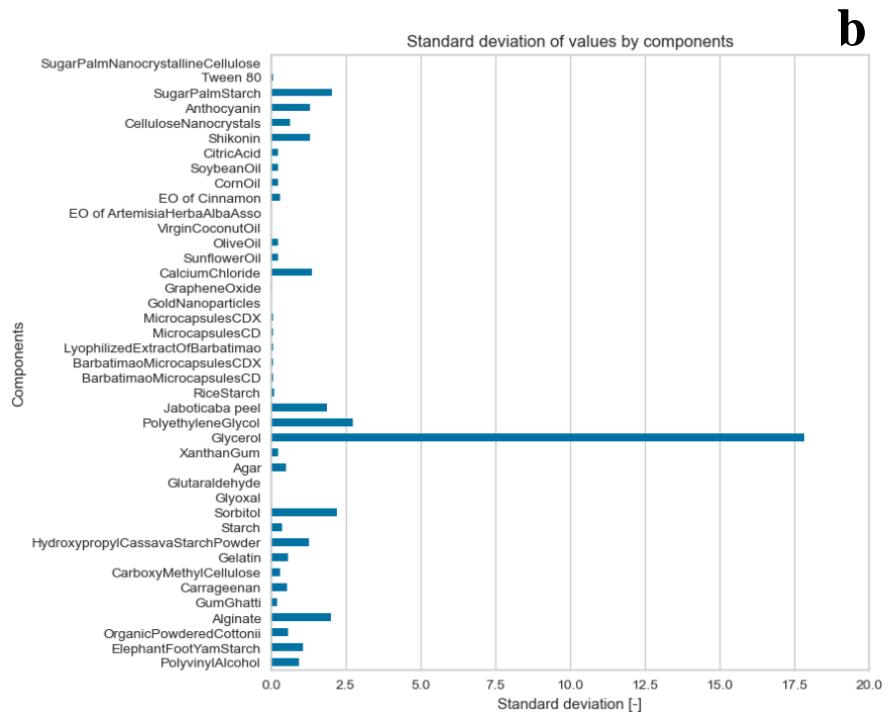

Figure S1. Features count values (A) and standard deviation (B) of each component.

Figure S2 show the jambu elbow plot, this indicates the variation of the inertia of the clustered sets as the number of clusters is varied.

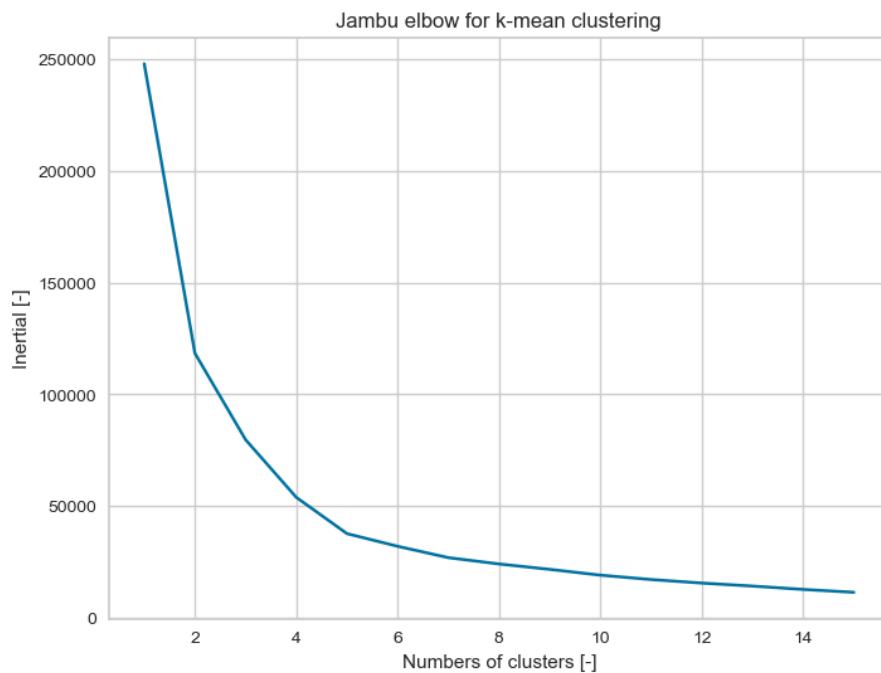

Figure S2. Jambu elbow for k-mean clustering

Table S3, S4, S5, S6 represent Pearson correlation by each cluster and mechanical properties considerate, it is possible to observe which components promote the respective property according to the subset of the extracted data.

Table S3. Pearson correlation for cluster a containing formulations with high elongation at break capacity and low tensile strength.
