

Supplementary Analyses

S1. Correlation between the Executive Functioning, Community Functioning, and Latencies

Correlation analyses were conducted for each group using the variables of depression (BDI-II), community functioning (SLICLS), P1, N1, and N2b latencies since there were significant between-group differences. Among HCs, significant moderate-large positive relationships existed between depression and N1 Comp X ISI latency ($p < 0.05$) (see Table S1). Among FMDD participants, significant moderate-large negative relationships existed between community functioning and depression, N1 compatible X 1-sec ISI latency, and N2b Comp X 0-sec ISI latency ($p < 0.05$). Also, there were significant moderate-large positive relationships also existed between community functioning N1 compatible X 0-sec ISI latency ($p < 0.05$) (see Table S2). Among RMDD participants, significant moderate-large positive relationships existed between depression and P1 incompatible X 0-sec ISI latency, N1 compatible-1-sec ISI latency, and N2b Comp X 0-sec ISI latency ($p < 0.05$). Also, significant moderate-large negative relationships existed between community functioning and N2b compatible X 0-sec ISI latency ($p < 0.05$) (see Table S3). Other results were not reported as they were intra-scale correlations or outside the aim of the correlational analysis. Also, researchers should be careful in overextending these correlational findings due to the negative effects of multiple testing.

S2: Group-based Scatterplot

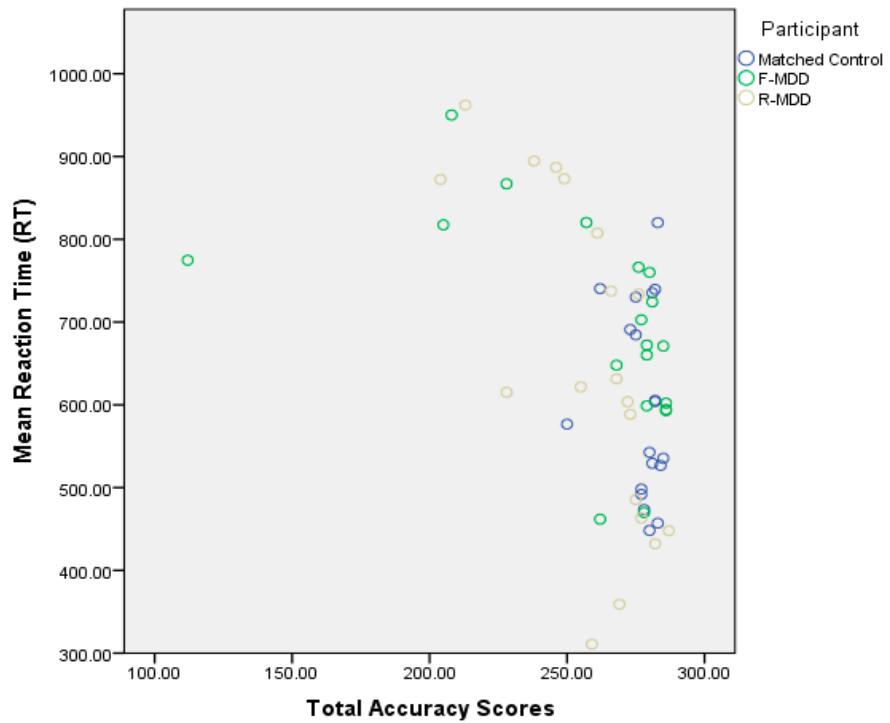

Figure S1: Group-based scatterplot of Accuracy on RT

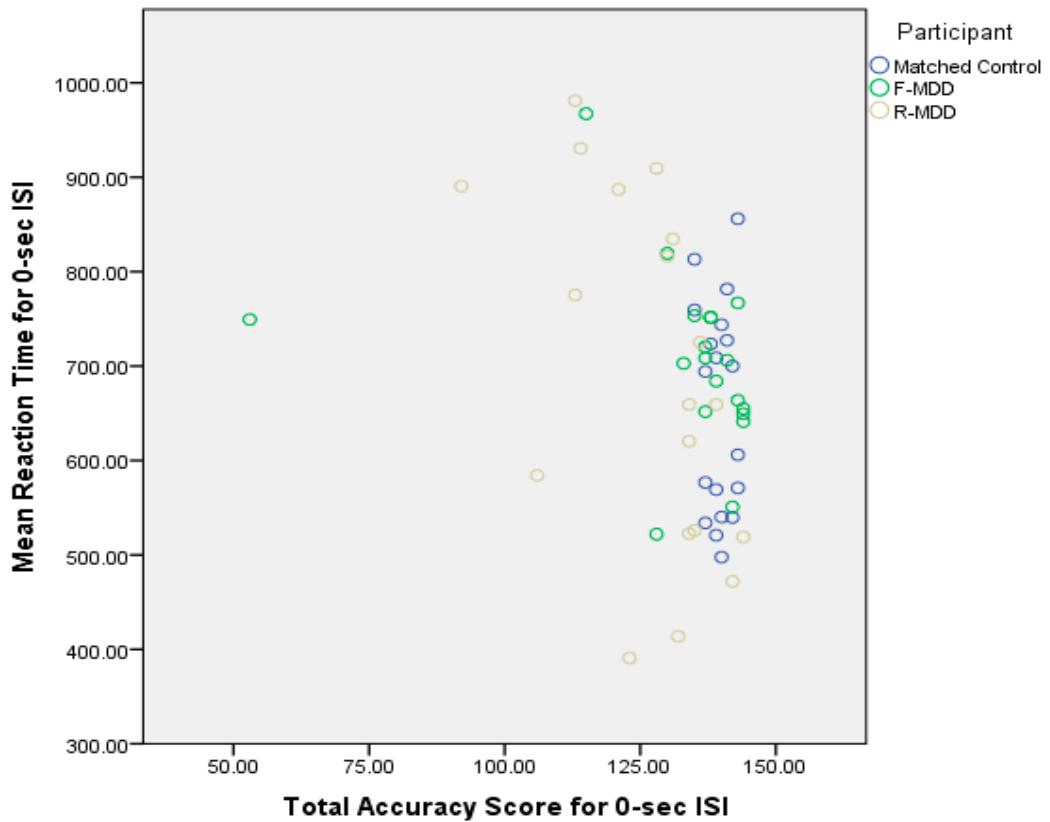

Figure S2: Group-based scatterplot of Accuracy on RT (0-sec ISI)

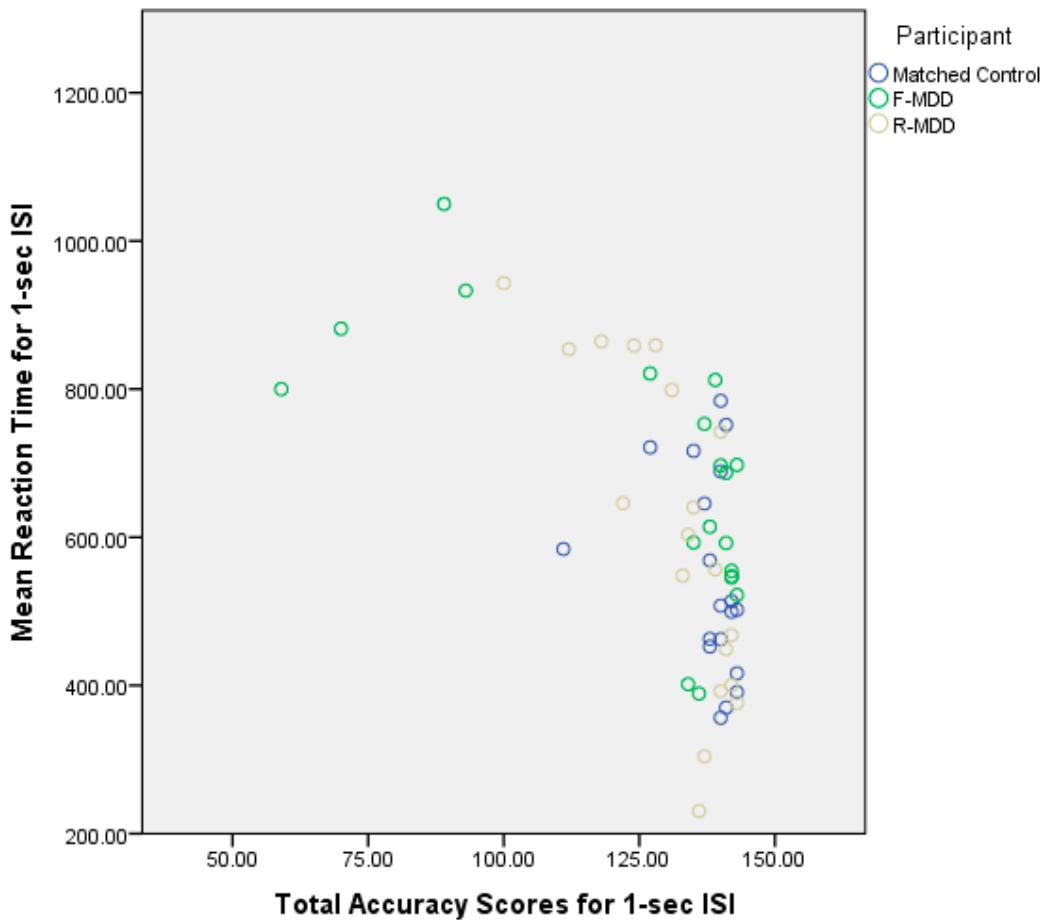

Figure S3: Group-based scatterplot of Accuracy on RT (1-sec ISI)

Figures S1 to S3 showed a data that were mostly clustered around the maximum accuracy score for the task. Figures S1 and S2 had a data that was suggestive of being an outlier. However, there was no significant between-group differences after removing it from the data. Hence, it was maintained in order to help match the other participants (i.e., participants in groups were matched).

S3. Contingent Negative Variation (CNV)

There was a significant interaction effect between intergroup (Group factor) and intragroup factors (Comp and Topo factors) on CNV amplitude ($F(2,54) = 4.000, p = .024, \eta_p^2 = .129$). Among RMDD outpatients, there was a more negative-going CNV amplitude during incompatible condition ($-5.95 \pm 1.04 \mu\text{V}$) than compatible condition ($-4.73 \pm 0.94 \mu\text{V}$) at site Cz ($p < .024$). Furthermore, among each of the groups, it was observed that there was a more negative-going CNV amplitude at site Cz (HCs ($-4.67 \pm 0.94 \mu\text{V}$), FMDD ($-4.02 \pm 0.94 \mu\text{V}$) and RMDD ($-4.73 \pm 0.94 \mu\text{V}$) outpatients) than site Fz (HCs ($-1.59 \pm 0.58 \mu\text{V}$), FMDD ($-1.21 \pm 0.58 \mu\text{V}$) and RMDD ($-2.22 \pm 0.58 \mu\text{V}$) during compatible condition (all $p < .000$) and a more negative-going CNV amplitude at site Cz (HCs ($-4.28 \pm 1.04 \mu\text{V}$), FMDD ($-4.44 \pm 1.04 \mu\text{V}$) and RMDD ($-5.95 \pm 1.04 \mu\text{V}$) outpatients) than site Fz (HCs ($-1.52 \pm 0.64 \mu\text{V}$), FMDD ($-0.67 \pm 0.64 \mu\text{V}$) and RMDD ($-3.06 \pm 0.64 \mu\text{V}$) outpatients) during incompatible condition (all $p < .000$). No other significant interaction effects were observed (all $p > .05$).
