Abstract: *Piper* spices represent an inexhaustible reservoir of bioactive compounds that may act as drug leads in natural product research. The aim of this study was to investigate a series of methanolic fruit extracts obtained from *P. nigrum* (black, green, white and red), *P. longum* and *P. retrofractum* in comparative phytochemical and multi-directional biological (antimicrobial, antioxidant, anti-enzymatic and anti-melanogenic) assays. The metabolite profiling revealed the presence of 17 piperamides, with a total content of 247.75–591.42 mg piperine equivalents/g. Among the 22 tested microorganism strains, *Piper* spices were significantly active (MIC < 0.1 mg/mL) against the anaerobes *Actinomyces israelii* and *Fusobacterium nucleatum*. The antioxidant and anti-enzymatic activities were evidenced in DPPH (10.64–82.44 mg TE/g) and ABTS (14.20–77.60 mg TE/g) radical scavenging, CUPRAC (39.94–140.52 mg TE/g), FRAP (16.05–77.00 mg TE/g), chelating (0–34.80 mg EDTAE/g), anti-acetylcholinesterase (0–2.27 mg GALAE/g), anti-butyrylcholinesterase (0.60–3.11 mg GALAE/g), anti-amylase (0.62–1.11 mmol ACAE/g) and anti-glucosidase (0–1.22 mmol ACAE/g) assays. Several *Piper* extracts (10 µg/mL) inhibited both melanin synthesis (to 32.05–60.65% of αMSH+ cells) and release (38.06–45.78% of αMSH+ cells) in αMSH-stimulated B16F10 cells, partly explained by their tyrosinase inhibitory properties. Our study uncovers differences between *Piper* spices and sheds light on their potential use as nutraceuticals or cosmeceuticals for the management of different diseases linked to bacterial infections, Alzheimer's dementia, type 2 diabetes mellitus or hyperpigmentation.

Keywords: *Piper*; piperamides; antimicrobial; anti-tyrosinase; anti-melanogenic; natural bioactive agents

1. Introduction

The genus *Piper* (Piperaceae, pepper) gathers around 1500–2000 species of herbs, shrubs, vines or trees, widely distributed in the tropical regions of southeast Asia and Oceania, Western and Central Africa, Central and South America [1,2]. Numerous members of the genus are valued as spices and have been used for thousands of years as flavor, color and aroma enhancers and preservatives [3]. Considered the 'king of spices' due to its massive share in the global spice market, *P. nigrum* L. is also used in traditional

Chinese and Ayurvedic medicine to treat fever, colds, colic and gastrointestinal ailments [4]. Nevertheless, the fruits of *P. nigrum* (peppercorns) are differently processed, leading to numerous commercial varieties. For instance, black peppers represent the unripe berries allowed to dry until a wrinkled dark layer is formed, whereas white peppers are ripe fruits from which the outer layer has been removed. Green peppers are unripe berries picked at the same stage of ripeness as black peppercorns, while red peppers are unhulled ripe berries; both green and red peppercorns are dried under special color-preserving conditions [3].

The oblong, blunt and blackish-green fruits of *P. longum* L. are also among the most important species in the genus, being ethnomedicinally recommended as analgesic, immunomodulator, aphrodisiac or emmenagogue to treat respiratory or gastrointestinal disorders, post-partum hemorrhage, epilepsy, diabetes and rheumatoid arthritis [5,6]. Also elongated in shape, the fruits of *P. retrofractum* Vahl. (syn. *P. chaba* Hunter, *P. officinarum* (Miq.) C. DC.) are traditionally used as digestive, tonic, carminative in asthma, bronchitis, gastrointestinal ulcers, diarrhea or postpartum hemorrhage [1,7].

Spices from the genus *Piper* represent a promising lead in natural product research, as extracts or extract-derived bioactive compounds have been shown to act as multiple pharmacological agents with antioxidant, antimicrobial, anti-proliferative, anti-inflammatory, anti-hyperglycemic, anti-hyperlipidemic, cardio-vasculo-protective and neuroprotective effects [4,6]. Among the diverse specialized metabolites produced by the genus *Piper* (e.g., essential oils, flavonoids, lignans), piperamides are considered the key bioactive molecules [2]. As the main constituent of *P. nigrum* and *P. longum*, piperine was shown to possess analgesic, anti-depressant, anti-inflammatory and hepatoprotective effects in cell-free, cell-based and animal models [8]. Acyl coenzyme A-cholesterol acyltransferase, 5'-adenosine monophosphate-activated protein kinase-p38 mitogen-activated protein kinase signaling pathway, P-glycoprotein and different ion channels are among the most promising molecular targets of piperine [9,10]. In addition, other piperamides, such as pipernonaline, retrofractamide B, guineensine, *N*-isobutyl-2,4-octadecadienamide, *N*-isobutyl-2,4,14-eicosatrienamide and piperanine exhibited gastro-protective effects in indomethacin- and ethanol-induced gastric lesions in rats, whereas piperolein B, retrofractamide C, pipernonaline and dehydropipernonaline were reported to act as diacylglycerol acyltransferase inhibitors, with putative implications in the treatment of obesity [11]. Furthermore, guineensine has been shown to be a nanomolar endocannabinoid reuptake inhibitor with potent in vivo cannabimimetic effects [12,13].

As a continuation of our multi-group research efforts to screen for new phytochemical drug leads for the management of infectious diseases, Alzheimer's disease, type 2 diabetes mellitus and skin disorders, the biological and metabolite profiling of *P. nigrum* (black, green, white and red), as well as of *P. longum* and *P. retrofractum*, was performed. The comprehensive phytochemical characterization of *Piper* spices was carried out by state-of-the-art spectro-chromatographic techniques, whereas the antibacterial and antifungal properties were assessed on a panel of reference microorganisms. The antioxidant and anti-enzymatic activities were investigated with regard to radical scavenging, metal reducing and chelating, anti-cholinesterase, anti-amylase, anti-glucosidase and anti-tyrosinase assays. Lastly, the anti-melanogenic effects were evaluated in murine melanoma B16F10 cells stimulated with α -melanocyte stimulating hormone (α MSH).

2. Materials and Methods

2.1. Plant Material and Extraction

Dried fruits (peppercorns) of various *Piper* spices (Table 1) were bought from various local European markets, identified by the authors (A.T., K.S.W.) and stored in Department of Pharmacognosy, Grigore T. Popa University of Medicine and Pharmacy Iasi (Romania). The dried peppercorns (20 g from each material) were pulverized with a grinding machine (Rommelsbacher ElektroHausgeräte GmbH, Dinkelsbühl, Germany) and subjected to ultrasound-assisted extraction with methanol (200 mL) for 30 min at 40 °C, for three

consecutive times. The filtered and pooled extracts were evaporated to dryness. The extraction yields are provided for each sample in Table 1.

Table 1. Extraction yields, total phenolic and flavonoid contents in the methanolic fruit extracts obtained from different spices of genus *Piper*.

Sample	Voucher	Extraction Yield	TPC (mg GAE/g)	TFC (mg RE/g)	
<i>P. nigrum</i> L.	Black1	PN1/102019	10.5%	40.96 ± 0.42 ^b	10.03 ± 0.22 ^b
	Black2	PN5/102019	10.9%	40.80 ± 0.45 ^b	9.12 ± 0.32 ^b
	Black3	PN6/102019	11.9%	36.71 ± 0.18 ^c	1.44 ± 0.15 ^e
	White	PN2/1020219	7.7%	42.11 ± 1.06 ^b	4.66 ± 0.30 ^c
	Green	PN3/102019	12.5%	58.90 ± 1.84 ^a	18.37 ± 0.27 ^a
	Red	PN4/102019	14.5%	41.41 ± 1.00 ^b	5.42 ± 0.32 ^c
<i>P. longum</i> L.	PL1/112019	18.3%	29.53 ± 0.25 ^d	3.01 ± 0.03 ^d	
<i>P. retrofractum</i> Vahl.	PR1/112019	10.1%	32.60 ± 0.22 ^e	19.70 ± 0.13 ^d	

Data are presented as mg gallic acid equivalents (GAE)/g extract for the total phenolic content (TPC) and mg rutin equivalents (RE)/g extract for total flavonoid content (TFC) and represent the mean values ± S.D. of three determinations; values in the same column sharing different superscript letters are significantly different at $p < 0.05$.

2.2. Phytochemical Characterization

Total phenolic content (TPC) and total flavonoid content (TFC) of *Piper* methanolic extracts were determined as previously described [14,15], with the results expressed as mg gallic acid equivalents (GAE)/g extract for TPC and mg rutin equivalents (RE)/g extract for TFC. The profiling of piperamides was performed by liquid chromatography with high resolution tandem mass spectrometry (LC-HRMS/MS), based on a method detailed by Luca et al. [2]. The quantitative estimation of piperamides was carried out by liquid chromatography with diode array detection (LC-DAD), as previously presented [2]; the data are reported as mg piperine equivalents (PE)/g extract.

2.3. Antimicrobial Assay

The methanolic extracts of *Piper* spices were screened for their antibacterial and antifungal activities by micro-dilution method according to the European Committee on Antimicrobial Susceptibility Testing [16]. Mueller-Hinton (MH) broth and MH broth with 5% lysed sheep blood were used for the growth of non-fastidious and fastidious bacteria, respectively, whereas MH broth with 2% glucose was used for the growth of fungi. Minimum inhibitory concentrations (MIC) of the samples were determined in a panel of reference microorganisms. The following strains were used: Gram-positive bacteria (*Staphylococcus aureus* ATCC 25923, *Staphylococcus epidermidis* ATCC 12228, *Micrococcus luteus* ATCC 10240, *Bacillus cereus* ATCC 10876, *Enterococcus faecalis* ATCC 29212, *Streptococcus mutans* ATCC 25175, *Actinomyces israelii* ATCC 10049 and *Clostridium perfringens* ATCC 13124); Gram-negative bacteria (*Campylobacter jejunii* ATCC 33291, *Salmonella Typhimurium* ATCC14028, *Escherichia coli* ATCC 25922, *Proteus mirabilis* ATCC 12453, *Klebsiella pneumoniae* ATCC 13883, *Pseudomonas aeruginosa* ATCC 90271, *Bacteroides fragilis* ATCC 10240, *Prevotella intermedia* ATCC 25611, *Fusobacterium nucleatum* ATCC 25586 and *Veillonella parvula* ATCC 10790); fungi (*Candida glabrata* ATCC 90030, *C. albicans* ATCC 102231 and *C. parapsilosis* ATCC 22019).

2.4. Antioxidant, Cholinesterase, Amylase and Glucosidase Assays

The antioxidant activity of *Piper* samples was determined by 1,1-diphenyl-2-picrylhydrazyl (DPPH) and 2,2'-azino-bis(3-ethylbenzothiazoline-6-sulfonic acid) (ABTS) radical scavenging, cupric reducing antioxidant capacity (CUPRAC), ferric reducing antioxidant power (FRAP), metal chelating (MCA) and phosphomolybdenum (PBD) assays [14,15]. DPPH, ABTS, CUPRAC and FRAP activities are expressed as mg trolox equivalents (TE)/g extract.

In MCA, the data were presented as mg EDTA equivalents (EDTAE)/g extract, whereas in PBD assay, the results are provided as mmol TE/g extract. Acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) inhibition was assessed as described in [14,15] and expressed as mg galanthamine equivalents (GALAE)/g extract, while amylase and glucosidase inhibition [14,15] is reported as mg acarbose equivalents (ACAE)/g extract.

2.5. Cell Viability Assay

Murine melanoma B16F10 cells (ATCC[®] CRL-6475, LGC Standards, Łomianki, Poland) and immortalized human keratinocyte HaCaT cells (Cell Lines Service GmbH, Eppelheim, Germany) were maintained in Dulbecco's Modified Eagle's Medium (DMEM) containing 4.5 g/L glucose and supplemented with 10% fetal bovine serum (FBS). The cells were cultured at 37 °C in a humidified atmosphere with 5% CO₂. Neutral red uptake (NRU) assay was performed as described previously by Repetto et al. [17]. Briefly, after seeding in 96-well plates (3 × 10³ cells/well), cells were grown overnight and treated with different concentrations of *Piper* methanolic extracts (10–200 µg/mL) or piperine (10–200 µg/mL). Control cells, containing appropriate volumes of the solvent (DMSO), were kept under the same conditions. After 72 h (for B16F10 cells) or 48 h (for HaCaT cells), the cells were incubated for 3 h with neutral red solution (33 µg/mL) in conditioned medium containing 1% FBS. The cell morphology was examined with an inverted microscope (Nikon Eclipse, Nikon, Japan) and documented using an Invenio II camera (DELTAPIX, Smørum, Denmark). The cells were then rinsed with Dulbecco's phosphate buffered saline (DPBS) and lysed using acidified ethanol solution (50% v/v ethanol, 1% v/v acetic acid and 49% H₂O). The absorbance of the released neutral red was measured at λ = 540 nm using a FilterMax F5 microplate reader (Molecular Devices, San Jose, CA, USA) and corrected by the absorbance at λ = 620 nm. Mean measured values for the lysate from control cells were set as 100% and used to calculate the percentage of cell viability in the other samples.

2.6. Melanin Assay

After seeding in 6-well plates (0.5 × 10⁵ cells/well), B16F10 cells were grown overnight and treated with *Piper* methanolic extracts (10 µg/mL), piperine (10 µg/mL) or the positive control kojic acid (10 µg/mL). Melanin production was stimulated with αMSH (10 nM). After 72 h, the conditioned medium and cell pellets were collected. Negative control cells, containing appropriate volumes of solvent (DMSO), were kept under the same conditions, but in the absence of αMSH stimulation. Next, cell pellets were dissolved in 1 N NaOH and incubated for 2 h at 80 °C. Conditioned media and cell lysates were then transferred to a 96-well plate and the absorbance was measured at λ = 405 nm using the FilterMax F5 microplate reader. The content of protein in cell lysates was established by Bradford assay [18]. The melanin released in the conditioned medium and the melanin content in cell lysates (µg melanin/mg protein) were calculated with the help of synthetic melanin calibration curves. Mean measured values obtained for αMSH-stimulated control cells without the tested samples (αMSH+) were set as 100% and used to calculate the percentage of melanin release/content in the other samples.

2.7. Tyrosinase Assay

2.7.1. Mushroom Tyrosinase Assay

The inhibition of the monophenolase and diphenolase activities of mushroom tyrosinase was performed as previously described [19,20]. For the monophenolase inhibitory assay, 100 mM phosphate buffer (PBS, pH = 6.8, 80 µL) was mixed with 20 µL of *Piper* methanolic extracts (10 µg/mL), piperine (10 µg/mL) or kojic acid (10 µg/mL). After incubation at 25 °C for 10 min with 500 U/mL mushroom tyrosinase (20 µL), 2 mM L-tyrosine (80 µL) was added to the samples and incubated at 25 °C for additional 20 min. In the case of diphenolase inhibitory assay, PBS (120 µL) and samples (20 µL) were incubated for 10 min at 25 °C with mushroom tyrosinase (80 µL). Following the addition of 4 mM L-DOPA (40 µL), the samples were further incubated for additional 20 min at 25 °C. In both

assays, the control, containing appropriate volumes of solvent (DMSO), was obtained under the same conditions. Next, the formation of dopachrome was measured spectrophotometrically at $\lambda = 450$ nm using the FilterMax F5 microplate reader. Mean measured values obtained for the solvent control were set as 100% and used to calculate the percentage of enzyme activity in the other samples.

2.7.2. Murine Tyrosinase Assay

The inhibition of murine tyrosinase activity was assessed using B16F10 cell lysate, as previously described [19,20]. The B16F10 cells (8×10^6) were lysed for 1 h with 1% Triton X-100 in PBS (5 mL) in an ultrasound ice-cold water bath. After centrifugation (10 min at 13,000 rpm), the supernatant was collected as murine tyrosine solution and the protein concentration was measured using a DC Protein Assay kit (Bio-Rad, Hercules, CA, USA). Cell lysate containing 20 μ g protein was mixed with 20 μ L of *Piper* methanolic extracts (10 μ g/mL), piperine (10 μ g/mL) or kojic acid (10 μ g/mL), 4 mM L-DOPA (40 μ L) and PBS (up to 200 μ L). The control, containing appropriate volumes of solvent (DMSO), was obtained under the same conditions. After incubation for 4 h at 37 °C, the absorbance was measured spectrophotometrically at $\lambda = 450$ nm using the FilterMax F5. Mean measured values obtained for the solvent control were set as 100% and used to calculate the percentage of enzyme activity in the other samples.

2.8. Statistical Analysis

All non-cell-based tests were performed in three replicates, and the results are expressed as mean \pm standard deviation (S.D.). The cell-based assays were performed in triplicate, with data representative for at least three individual experiments and expressed as mean \pm standard error of mean (S.E.M.). Statistical analysis was performed in Origin-Pro2020 (OriginLab) using ANOVA with Turkey's post hoc test; $p < 0.05$ was considered statistically significant.

3. Results and Discussion

3.1. Phytochemical Characterization

Piper fruits are acknowledged as valuable and rich sources of a wide range of specialized metabolites, such as piperamides, flavonoids, lignans and essential oils [6]. In the current work, the methanolic fruits extracts of *P. nigrum*, *P. longum* and *P. retrofractum* were phytochemically characterized with regard to TPC, TFC as well as the piperamides' profile (LC-HRMS/MS) and content (LC-DAD).

TPC was generally higher in the six varieties of black pepper (36.71–58.90 mg GAE/g) than in *P. longum* (29.53 mg GAE/g) and *P. retrofractum* (32.60 mg GAE/g) (Table 1). TFC showed a high variability, with *P. retrofractum* (19.70 mg RE/g) displaying the highest values, followed by green pepper (18.37 mg RE/g); on the contrary, black pepper 3 (1.44 mg RE/g) exhibited a very low TFC (Table 1). Our results are comparable with previous literature data. For instance, Zarai et al. [21] reported 37.48 mg GAE/g and 3.01 mg/g quercetin equivalents/g in the methanol extract of *P. nigrum*.

The LC-HRMS/MS profiling of piperamides was performed according to dereplication strategies carefully presented in a previous work for a series of hexane *Piper* extracts [2]. To estimate the piperamides' content, the chromatographic and spectrometric LC-HRMS/MS identification data (UV, HRMS, HRMS/MS, molecular formula) from Table 2 were correlated with the LC-DAD data, as detailed in [2].

Table 2. LC-HRMS/MS data of piperamides tentatively identified the methanolic fruit extracts obtained from different spices of genus *Piper*.

HRMS, high-resolution mass spectra; MF, molecular formula; T_R retention time; UV, ultraviolet.

Piperolactam C (**1**) and piperlongumine (**2**) were solely found in *P. retrofractum*, whereas piperlyline (**3**) was present only in *P. nigrum* (5.81–15.40 mg/g). The amount of piperlonguminine (**4**) varied from 2.72 mg/g in white pepper to 16.87 mg/g in *P. longum*. Piperine (**5**) was by far the most abundant constituent in almost analyzed samples, with its highest values in white and green peppers (308.36–315.19 mg/g); in comparison, *P. retrofractum* had ~3-fold lower values of piperine. Nevertheless, the major piperamide in *P. retrofractum* was represented by pellitorine (**8**; 206.95 mg/g), a constituent found in levels 5 to 25 times lower in the other spices. Quantified as sum of stereoisomers, piperettines (**6**) showed significantly high amounts in *P. nigrum* varieties (21.51–70.60 mg/g), while their content was very low in the other two investigated *Piper* species (Table 2).

Piperolein A (**7**) and piperolein B (**14**) were absent in *P. longum*, whereas their levels in the other spices varied from 5.84 mg/g (red pepper) to 28.97 mg/g (white pepper) and from 2.70 mg/g (*P. retrofractum*) to 17.26 mg/g (black pepper 1), respectively. Pipericallosine (**9**), piperlongumine (**11**; 47.62 mg/g) and N-Isobutyl-2,4,12-octadecatrienamamide (**17**; 82.65 mg/g) reached their highest values in *P. longum*. On the contrary, samples of *P. nigrum* were characterized by the highest amounts of dehydropiperlongumine (**10**; 22.23 mg/g), neopeollitorine B (**12**; 7.89 mg/g), retrofractamide B (**13**; 22.07 mg/g), piperundecalidine (**15**; 7.66 mg/g) and guineensine (**16**; 42.53 mg/g). The total piperamide content revealed a variable profile from 247.75 to 591.42 mg/g, in the following increasing order: red pepper < *P. retrofractum* < black pepper 3 < *P. longum* < white pepper ~ black pepper 2 < green pepper ~ black pepper 1 (Table 3).

Table 3. Piperamide content in the methanolic fruit extracts obtained from different spices of genus *Piper*.

No.	Compound	<i>P. nigrum</i>						<i>P. longum</i>	<i>P. retrofractum</i>
		Black 1	Black 2	Black 3	White	Green	Red		
		mg PE/g Extract

Data are presented as mg piperine equivalent (PE)/g extract and represent the mean values ± S.D. of three determinations; values in the same row sharing different superscript letters are significantly different at $p < 0.05$.

3.2. Antimicrobial Activity

The extensive usage of antibiotics and the rapid emergence of multi-drug resistant pathogens represent serious issues for modern medicine. Numerous solutions are under current investigation, including the screening and identification of novel plant-based antimicrobials with superior efficiency and safety profiles [22]. In the present study, the antimicrobial activity of the eight methanolic fruit extracts of *Piper* spp. was assessed by micro-dilution method, with results reported as MIC values (Table 4). The sensitivity of the tested strains varied based on the *Piper* variety/species, microorganism group or species. The criteria proposed by Kuete and Efferth [23] were used to categorize the observed antimicrobial activity into three groups: significant activity (MIC < 0.1 mg/mL), moderate activity (0.1 < MIC < 0.625 mg/mL) and weak/no activity (MIC > 0.625 mg/mL). For instance, a moderate activity (MIC = 0.125–0.5 mg/mL) was noticed against *S. aureus* for black peppers 2 and 3, white pepper, green pepper and *P. retrofractum*, whereas only green and red peppers were found to be active against *S. epidermidis*. Except for *P. longum*, all other investigated spices presented a moderate activity against *M. luteus*, with black peppers 1 and 2 and green pepper as the most potent agents. Black peppers 1 and 3, white pepper and *P. retrofractum* exhibited MIC values of 0.5 mg/mL against *Bacillus cereus*. The anaerobic *A. israelii* showed a particular sensitivity toward all *Piper* samples (MIC = 0.0625–0.5 mg/mL), with black pepper 3 and white pepper displaying the strongest inhibitory effects. The investigated spices also demonstrated weak activity against aerobic Gram-negative bacteria (MIC > 2 mg/mL), whereas the anaerobic Gram-negative bacteria (*B. fragilis*, *P. intermedia*, *F. nucleatum*, *V. parvula*) were considerably more sensitive. For instance, a MIC value of 0.0625 mg/mL was noticed for black pepper 3, green pepper and *P. retrofractum* against *F. nucleatum*, while black peppers 1–2, white and red peppers exhibited a MIC value of 0.125 mg/mL against the same pathogen. Concerning the yeast strains, all spices (except for *P. longum*) displayed moderate antifungal activity (MIC = 0.25–0.5 mg/mL), but only against *C. parapsilosis* (Table 4).

Table 4. Antimicrobial activity of the methanolic fruit extracts obtained from different spices of genus *Piper*.

Minimum inhibitory concentrations (MIC) present representative values of three determinations; the superscript numbers indicate the use of (1) vancomycin, (2) ciprofloxacin, (3) metronidazole and (4) nystatin as the standard drugs towards Gram-positive bacteria, Gram-negative bacteria, anaerobes and yeasts, respectively.

Previously, *P. nigrum* exhibited MIC values within a similar range (0.0625–0.5 mg/mL) against *S. aureus*, *S. epidermidis*, *Staphylococcus xylosus*, *B. cereus*, *E. faecalis*, *Listeria monocytogenes*, *P. aeruginosa*, *Salmonella Typhi*, *S. Typhimurium* or *E. coli* [21,24–26]. Regarding the antibacterial mechanisms of action, black pepper was shown to induce plasmolysis, decrease cell membrane permeability, inhibit the tricarboxylic acid pathway, increase intracellular pyruvic acid and reduce intracellular ATP levels [25]. The antibacterial properties of *P. longum* against *S. aureus*, *S. pyogenes*, *K. pneumoniae* [27] and *P. retrofractum* against *B. subtilis*, *S. aureus*, *E. faecalis*, *E. coli*, *K. pneumoniae*, *P. aeruginosa*, *S. Typhi*, *Vibrio parahaemolyticus* or *C. albicans* [28] have also been investigated.

However, to the best of our knowledge, the significant antibacterial activity of *Piper* spices against the anaerobic pathogens tested in this study has not been previously reported. Due to their slow growth rate, poly microbial nature and high resistance to conventional antimicrobial chemotherapy, the management of anaerobic infections is very challenging. *Actinomyces* spp. are often responsible for head and neck infections, aspiration pneumonia, intracranial abscesses or chronic mastoiditis, whereas *Bacteroides* spp. are predominant in intra-abdominal and other infections that originate from the gut flora. *Prevotella* spp. have been isolated from respiratory infections and their complications, while *Veillonella* spp. have been involved in periodontitis, osteomyelitis or endocarditis [29,30].

3.3. Antioxidant Activity

Used for more than 50 years, synthetic antioxidants, such as *tert*-butylhydroquinone, propylgallate or butylated hydroxytoluene, are nowadays incriminated for carcinogenicity and banned in numerous countries [31,32]. Consequently, there is a high demand, especially from the food industry, for novel natural antioxidants as food preservatives. Previously, different *Piper* extracts have been shown to possess promising antioxidant effects, as evaluated by DPPH radical, superoxide radical, hydrogen peroxide, nitric oxide scavenging, FRAP, MCA, PBD or β -carotene bleaching assays [21,33–39].

In the current study, the antioxidant activity of the eight methanolic fruits extracts of *Piper* spp. was investigated through radical scavenging, metal chelating, metal reducing and PBD assays. Green and red peppers exhibited the most potent DPPH and ABTS radical scavenging activities (82.44 and 63.67 mg TE/g in DPPH assay for green and red peppers, respectively; 77.60 and 61.63 mg TE/g in ABTS assay for green and red peppers, respectively) (Figure 1a). The scavenging activity of the other samples decreased in the following order: black pepper 1 > white pepper > black pepper 2 > black pepper 3 > *P. retrofractum* > *P. longum*. A similar trend was observed in metal reducing assays (Figure 1b). CUPRAC varied from 37.36 mg TE/g in black pepper 3 to 140.52 mg/g TE in green pepper, whereas FRAP varied from 16.05 mg TE/g in *P. longum* and 77.00 mg/g TE in green pepper. In MCA (Figure 1c), only black pepper 1 (21.54 mg EDTAE/g), green pepper (4.64 mg EDTAE/g), black pepper 2 (12.35 mg EDTAE/g) and *P. retrofractum* (34.80 mg EDTAE/g) were found to be active. PBD assay (Figure 1d) revealed good total antioxidant properties of all investigated spices, with green pepper (1.35 mmol TE/g) and black pepper 1 (1.24 mmol TE/g) as the most potent spices.

With respect to the phytochemical composition (Table 1), it can be noticed that the most active samples in DPPH, ABTS, FRAP, CUPRAC and PBD assays were those with the highest TPC, whereas the four active samples in MCA were represented by those with the highest TFC; this could suggest the involvement of these two groups of specialized metabolites in the observed antioxidant properties.

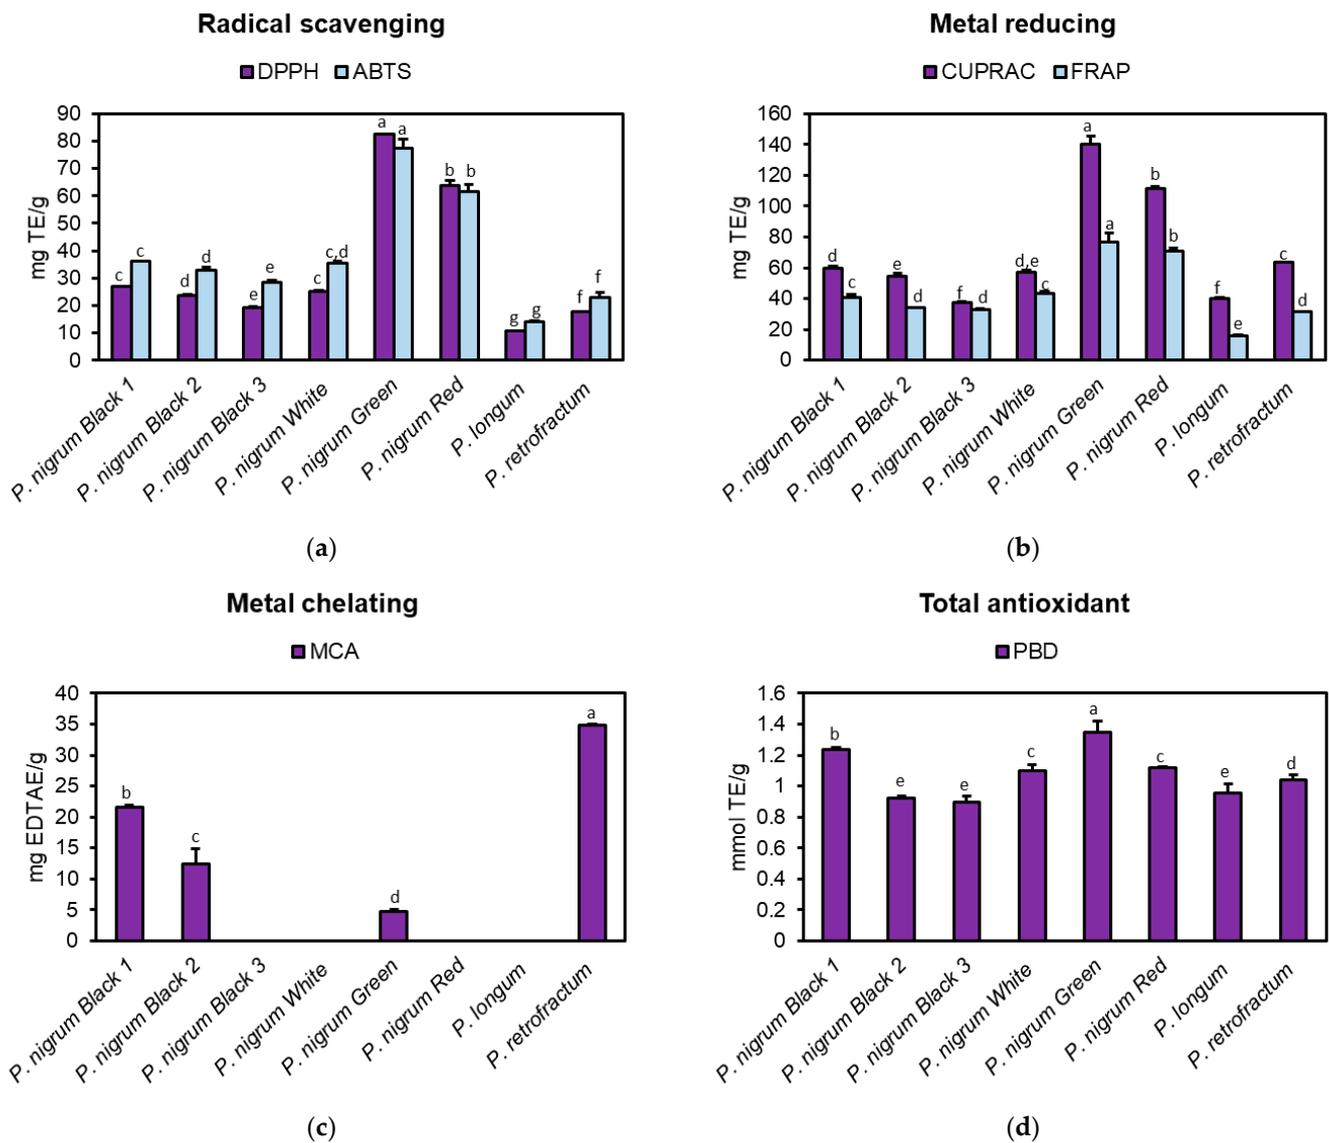

Figure 1. Antioxidant activity of the methanolic fruit extracts obtained from different species of genus *Piper* in (a) radical scavenging, (b) metal reducing, (c) metal chelating and (d) total antioxidant assays. Data are presented as mg Trolox equivalents (TE)/g extract in 1,1-diphenyl-2-picrylhydrazyl (DPPH), 2,2'-azino-bis(3-ethylbenzothiazoline) 6-sulfonic acid (ABTS) radical scavenging, cupric reducing antioxidant capacity (CUPRAC) and ferric reducing antioxidant power (FRAP) assays, mg EDTA equivalents (EDTAE)/g extract in metal chelating assay (MCA) and mmol TE/g extract in phosphomolybdenum (PBD) assay. Each bar represents mean \pm S.D. of three determinations; samples sharing different superscript letters are significantly different at $p < 0.05$.

3.4. Anti-Cholinesterase Activity

Alzheimer's disease (AD) is the most common cause of dementia and mainly affects the elderly population, provoking progressive cognitive decline, memory impairment and psycho-behavioral disorders. The presence of senile plaques, neurofibrillary tangles as well as a decrease in the cholinergic transmission are often noticed in the brain of patients with AD [40,41]. The inhibition of AChE and BChE, two sister enzymes that are responsible for the cleavage of the neurotransmitter acetylcholine, is one of the main currently investigated therapeutic strategies, with numerous natural products displaying promising anti-cholinesterase activity [42].

Within the frame of this study, all *Piper* species exhibited moderate anti-BChE effects, with values ranging from 0.60 mg GALAE/g (in *P. retrofractum*) to 3.11 mg GALAE/g (in

black pepper 3). In contrast, slightly lower anti-AChE properties were noticed, especially considering that, three spices (black peppers 2 and 3 and green pepper) were inactive, with highest activity observed at 2.35 mg GALAE/g in red pepper (Figure 2a). The anti-cholinesterase properties of the genus *Piper* have scarcely been reported. For instance, the ethyl acetate extract of *P. nigrum* exhibited efficient inhibition percentages of 61.5% against AChE and 90.6% against BChE at 100 µg/mL, whereas from the 21 isolated piperamides, piperine was the most potent inhibitor with IC₅₀ values of 63.16 µg/mL in AChE and 25.11 µg/mL in BChE, respectively [43]. On the other hand, the dichloromethane extract of *P. longum*, as well as piperine (IC₅₀ = 0.32 mM), pipericide (IC₅₀ = 0.61 mM) and guineensine (IC₅₀ = 1.61 mM), were shown to be able to inhibit AChE [44]. In another study, the methanolic extracts obtained from the fruits of *P. nigrum* and *P. retrofractum* displayed IC₅₀ values of 11.13 and 14.08 µg/mL against AChE, respectively [45].

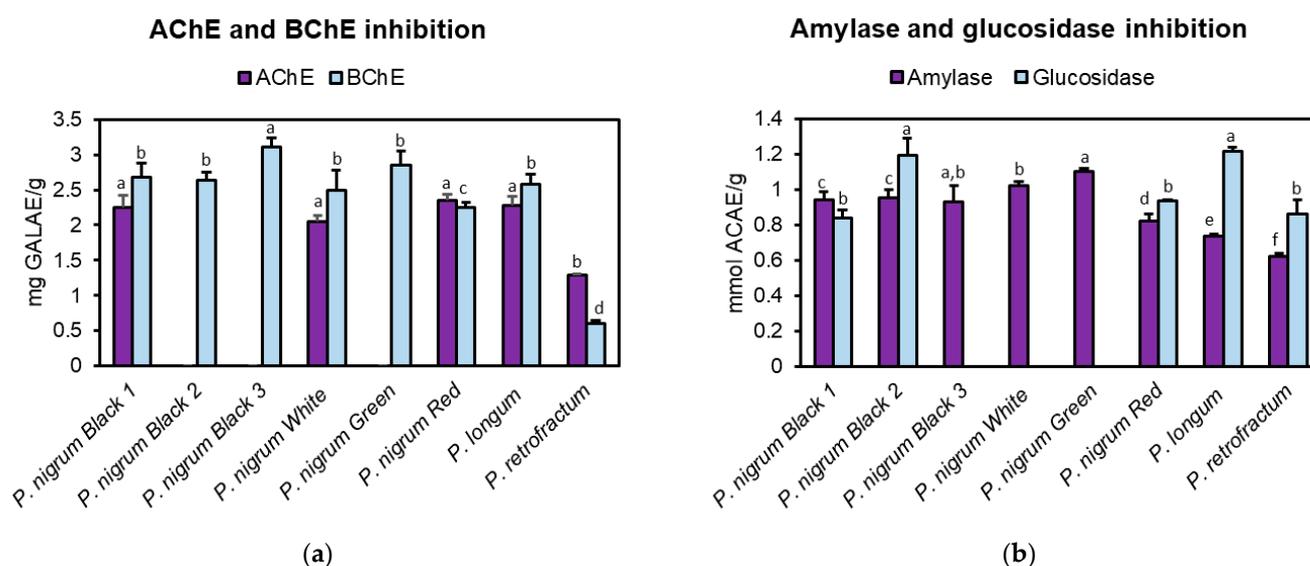

Figure 2. Acetylcholinesterase, butyrylcholinesterase, glucosidase and amylase inhibitory activity of the methanolic fruit extracts obtained from different spices of genus *Piper* in (a) cholinesterase and (b) amylase and glucosidase assays. Data are presented as mg galanthamine equivalents (GALAE)/g extract in acetylcholinesterase (AChE) and butyrylcholinesterase (BChE) assays and mg acarbose equivalents (ACAE)/g extract in amylase and glucosidase assays. Each bar represents mean \pm S.D. of three determinations; samples sharing different superscript letters are significantly different at $p < 0.05$.

3.5. Anti-Amylase and Anti-Glucosidase Activity

Type 2 diabetes mellitus is a chronic metabolic disorder characterized by high blood glucose levels as a consequence of an inefficient insulin functionality or secretion [46]. Inhibiting amylase and glucosidase, two key pancreatic enzymes that convert dietary polysaccharides into absorbable monosaccharides, represents a promising therapeutic approach. Several synthetic inhibitors (acarbose, voglibose, miglitol) are currently available, but they are often reported to produce serious side effects (flatulence, abdominal pain, diarrhea, and hepatotoxicity) [47]. Plants have been shown to be inexhaustible reservoirs of bioactive molecules with potential inhibitory activity against the two enzymes targeted in the management of type 2 diabetes [48]. As presented in Figure 2b, it can be noticed that black pepper 3, white pepper and green pepper were ineffective against glucosidase, whereas the activity of the remaining spices varied from 0.84 mmol ACAE/g (black pepper 1) to 1.22 mmol ACAE/g (*P. longum*). The extracts displayed anti-amylase effects in the following order: *P. retrofractum* < *P. longum* < red pepper < black peppers 1–3 < white pepper < green pepper. Previously, the ethanolic extract of *P. nigrum* and methanolic extract of *P. longum* were reported to possess anti-glucosidase activities, with IC₅₀ values of 216 and 112.90 µg/mL, respectively [47,49]. In addition, various piperamides isolated from *P. nigrum*, *P. longum* or *P. retrofractum*, such as piperine, pipericyclobutanamide D,

piperoside, pellitorine, brachystamide B, guineensine, and pipataline, were shown to exert significant to moderate glucosidase and, sometimes, amylase inhibitory effects [46,49,50].

3.6. Anti-Melanogenic Activity

Synthesized by the melanocytes and then transferred to keratinocytes, melanin is the main pigment in hair, skin and eyes. Nevertheless, the excessive production and accumulation of melanin can lead to hyperpigmentation disorders, such as melasma, senile lentigo or freckles [51,52]. Modulation of the melanogenesis by skin-lightening agents represents a promising therapeutic approach. However, the available drugs, such as kojic acid, arbutin, or hydroquinone, are banned in numerous countries, due to their serious side effects, such as irreversible depigmentation, dermatitis or skin cancer [52,53]. Therefore, there is an urgent need to screen for new safer depigmentation agents.

The potential melanin inhibitory effects of spices from the genus *Piper* were investigated in α MSH-stimulated murine melanoma B16F10 cells. Prior to the melanin assay, the influence of the *Piper* extracts on the viability of B16F10 cells and immortalized human HaCaT keratinocytes was investigated by the neutral red uptake assay. Despite a pronounced cytotoxicity, especially at higher concentrations (100–200 μ g/mL), no significant changes in either B16F10 or HaCaT cell viability was noticed at 10 μ g/mL (Figure 3); therefore, this concentration was considered safe and selected as test concentration for the melanin assay.

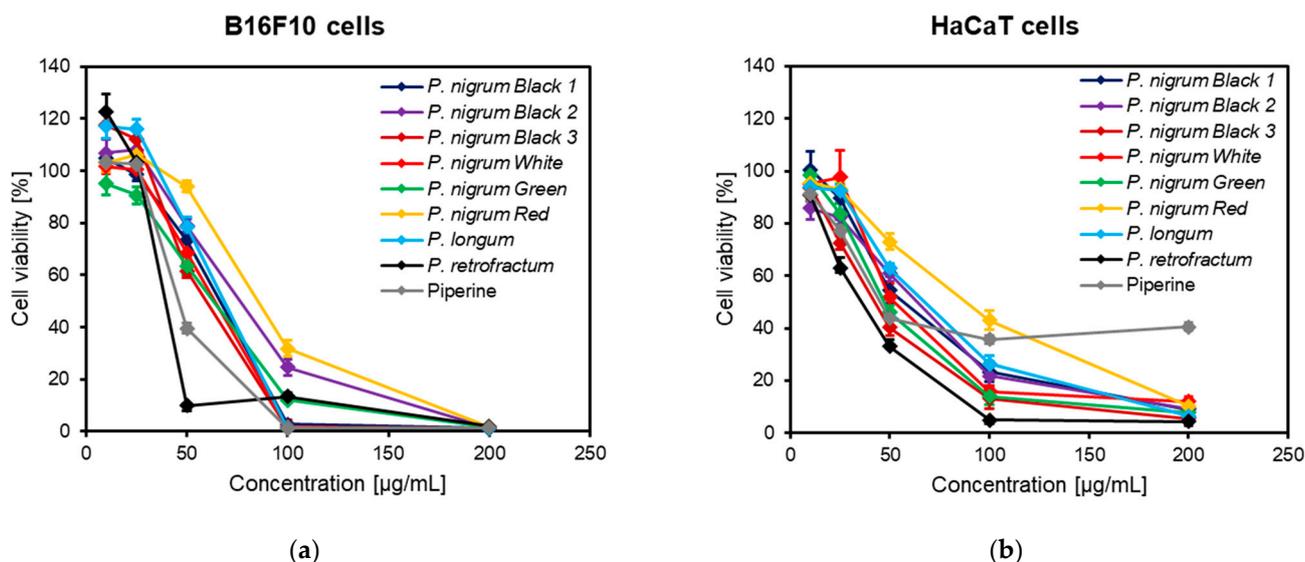

Figure 3. Concentration–response curves (10–200 μ g/mL) showing the effect of the methanolic fruit extracts obtained from different spices of genus *Piper* and piperine in (a) B16F10 and (b) HaCaT cells. Cells were seeded in 96-well plates (3×10^3 /well) and incubated for 72 h (B16F10 cells) or 48 h (HaCaT cells) with different concentrations of *Piper* extracts (10–200 μ g/mL) or piperine (10–200 μ g/mL). Data are presented as percentage cell viability (%) in comparison to the solvent (DMSO)-treated control cells, set at 100%.

As compared to the non-treated cells (α MSH $-$), the extracellular melanin content (=melanin release in the conditioned medium) and intracellular melanin content (=melanin content in the lysate) were both significantly increased by 2.7- and 4.3-fold in α MSH $+$ cells, respectively (Figure 4). When α MSH $+$ cells were treated with *Piper* samples (10 μ g/mL), a significant reduction of intracellular melanin content was noticed in white pepper (47.72% of α MSH $+$ cells), green pepper (60.65% of α MSH $+$ cells) and, especially, *P. longum* (32.05% α MSH $+$ cells). Furthermore, the same extracts also decreased the melanin release, with a relative extracellular melanin content of 38.06%, 40.68% and 45.78% of α MSH $+$ cells, respectively. Piperine (10 μ g/mL) was only able to reduce the intracellular melanin content (61.01% of α MSH $+$ cells), whereas the extracellular melanin release was not considerably impaired. Kojic acid (10 μ g/mL), the positive control for the melanin assay, significantly

downregulated both the intracellular (61.13% of α MSH+ cells) and extracellular (68.59% of α MSH+ cells) melanin content.

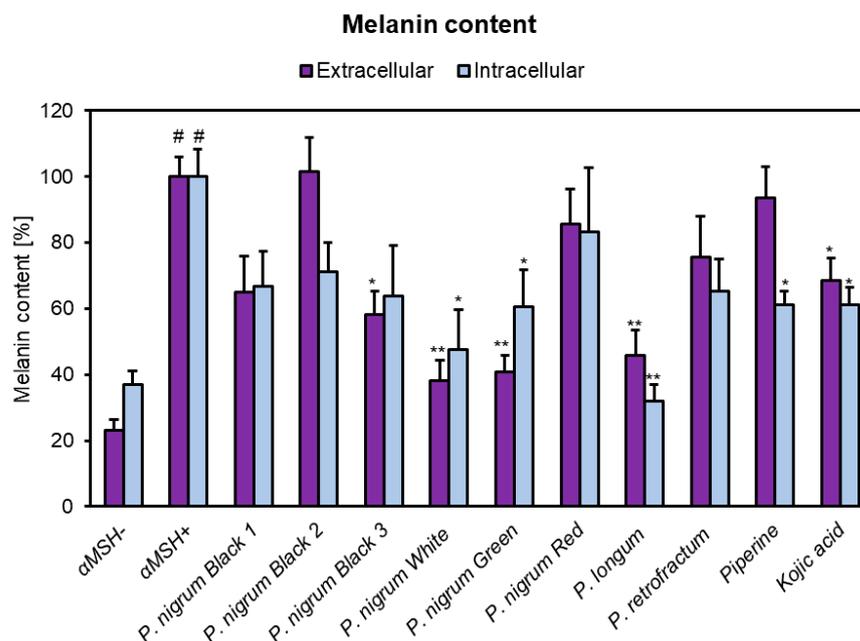

Figure 4. Melanin inhibitory activity in α MSH-stimulated B16F10 cells of the methanolic fruit extracts obtained from different spices of genus *Piper*, piperine and kojic acid. B16F10 cells were seeded in 6-well plates (0.5×10^5 /well) and incubated for 72 h with *Piper* extracts (10 μ g/mL), piperine (10 μ g/mL) or kojic acid (10 μ g/mL); melanin production was stimulated with α MSH (10 nM). Data are presented as the percentage of intracellular and extracellular melanin content in comparison to α MSH stimulated control (α MSH+) cells, set at 100%. Each bar represents the mean \pm S.E.M. of at least three independent experiments performed in triplicates; # $p < 0.001$ vs. non-stimulated (α MSH-) cells; * $p < 0.05$; ** $p < 0.01$; vs. α MSH+ cells.

To the best of our knowledge, there are no previous studies reporting on the anti-melanogenic activity of extracts obtained from various *Piper* spices. Nevertheless, the potential of different piperamides to inhibit the melanin production in α MSH-stimulated B16F10 cells has been documented. For instance, piperlongumine significantly reduced the total melanin production, by reducing the activity of tyrosinase and expression of several pro-melanogenic proteins, such as tyrosinase-related protein-1 (TRP-1), TRP2, microphthalmia-associated transcription factor (MITF) [54]. On the other hand, piperlongumine decreased the production of melanin by downregulating tyrosine expression at the transcription level via a reduction of cyclic adenosine monophosphate responsive element binding protein (CREB) phosphorylation [55,56].

3.7. Anti-Tyrosinase Activity

To investigate whether the anti-melanogenic effects of *Piper* spices in α MSH-stimulated B16F10 cells might be exerted via tyrosinase inhibition, monophenolase and diphenolase assays were performed. Tyrosinase is a key enzyme of melanogenesis, catalyzing the rate-limiting conversion of L-tyrosine to L-dihydroxyphenylalanine (L-DOPA) and subsequently to dopaquinone. Numerous plant extracts have previously been shown to exert tyrosinase inhibitory effects [20,57–59]. The influence on the monophenolase activity was investigated with mushroom tyrosinase (by adding L-tyrosine as substrate), whereas the influence on the diphenolase activity was evaluated with both mushroom and murine tyrosinase (by adding L-DOPA as substrate) (Figure 5). It was noticed that only the three black pepper samples (10 μ g/mL) significantly reduced the mushroom monophenolase activity (by 22–27%). With respect to the mushroom diphenolase, black, green and white

peppers showed moderate anti-tyrosinase effects (reductions by 13–16%). On the other hand, the activity of murine tyrosinase was significantly impaired by black (1–2) and white peppers and, additionally, by *P. longum* (activities between 78.36–85.22%). Piperine was unable to modulate the tyrosinase activity, whereas kojic acid, the positive control, decreased the mushroom monophenolase and diphenolase activity to 30.86% and 57.27%, respectively, with no significant effects on murine tyrosinase. Previously, the anti-tyrosinase activity of various *Piper* species, such as *P. retrofractum*, *P. caninum* Blume, *P. abbreviatum* Opiz, *P. erecticaule* C.DC., *P. stylosum* Miq., *P. magnibaccum* C.DC., and *P. betle* L., has been reported [60–63].

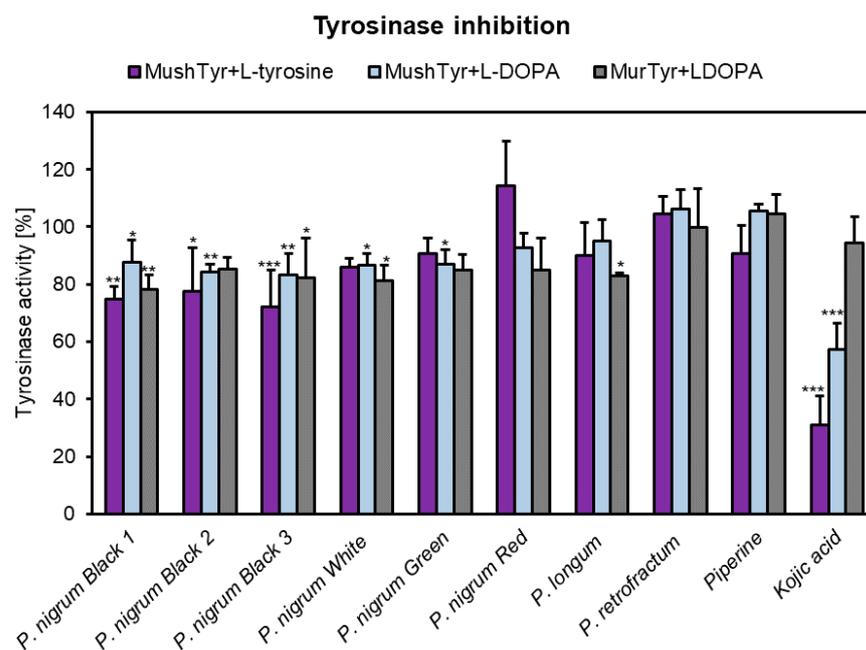

Figure 5. Tyrosinase inhibitory activity of the methanolic fruit extracts (10 $\mu\text{g}/\text{mL}$) obtained from different spices of genus *Piper*, piperine (10 $\mu\text{g}/\text{mL}$) and kojic acid (10 $\mu\text{g}/\text{mL}$). Data are presented as percentage of tyrosinase activity in comparison to solvent (DMSO) control, set at 100%. Each bar represents the mean \pm S.D. of three determinations; * $p < 0.05$; ** $p < 0.01$; *** $p < 0.001$ vs. control.

It is worth mentioning that the decrease in the melanin content in B16F10 cells treated with *Piper* extracts might result not only from the direct modulation of tyrosinase activity, but also from the transcriptional control of genes involved in the melanogenesis pathway or post-transcriptional modification of tyrosinase leading to enzyme degradation [64]. The potential involvement of *Piper* compounds in these pathways requires further investigation.

4. Conclusions

In this work, the phytochemical and multifunctional biological profiling of four varieties of *P. nigrum* (black, green, white and red) and two other *Piper* species, namely *P. longum* and *P. retrofractum*, was presented. Firstly, a comprehensive metabolite characterization by TPC, TFC, LC-HRMS/MS and LC-DAD was performed, revealing significant levels of bioactive piperamides, such as piperine, piperlongumine, piperlonguminine, retrofractamide B, guineensine, pipernonaline, or *N*-isobutyl-2,4,12-octadecatrienamamide. Then, the spices were assessed for their antibacterial and antifungal properties on a panel of 22 reference microorganisms. Beside a moderate activity against *Staphylococcus aureus*, *S. epidermidis*, *M. luteus*, *B. cereus* and *C. parapsilosis* (MIC = 0.125–0.5 mg/mL), several samples, such as black, green, white peppers or *P. retrofractum*, were particularly active (MIC = 0.0625–0.125 mg/mL) against anaerobe species, such as *A. israelii*, *B. fragilis*, *P. intermedia*, *F. nucleatum* and *V. parvula*. A potent antioxidant activity of the investigated spices was revealed, as evaluated by several complementary tests, such as radical scavenging,

metal reducing, chelating and phosphomolybdenum assays. With respect to the modulation of enzymes targeted in the management of Alzheimer's disease (acetylcholinesterase, butyrylcholinesterase) and type 2 diabetes mellitus (amylase, glucosidase), the current data suggest moderate inhibitory effects of *Piper* spices against the investigated enzymes. Several *Piper* extracts, namely white pepper, green pepper and *P. longum*, inhibited both the melanin synthesis (to 32.05–60.65% of α -MSH+ cells) and melanin release (38.06–45.78% of α -MSH+ cells) in α -MSH-stimulated B16F10 cells at 10 μ g/mL, a non-toxic concentration in both B16F10 and HaCaT cells. The anti-melanogenic properties could be partly explained by the moderate inhibition of murine tyrosinase (tyrosinase activities between 78.36–85.22%).

By evaluating the poly pharmacological potential of a series of *Piper* varieties and species, globally available and used as spices, our study shows similarities and differences between the investigated *Piper* samples. This could inspire future research into the use of *Piper* nutraceuticals or cosmeceuticals in the management of infectious diseases, Alzheimer's dementia, type 2 diabetes mellitus or hyperpigmentation disorders.

Author Contributions: Conceptualization, S.V.L., A.T. and K.S.-W.; methodology, S.V.L., K.G.-B., G.Z. and I.K.-G.; software, S.V.L., K.G.-B., G.Z., K.C. and I.K.-G.; validation, S.V.L., K.G.-B., A.T., G.Z., I.K.-G. and K.S.-W.; formal analysis, S.V.L., K.G.-B., G.Z., K.C. and I.K.-G.; investigation, S.V.L., K.G.-B., M.S.-G., K.C. and I.K.-G.; resources, S.V.L., K.G.-B., G.Z., I.K.-G., M.M. and K.S.-W.; data curation, S.V.L., G.Z., J.G.; writing—original draft preparation, S.V.L. and A.T.; writing—review and editing, K.G.-B., G.Z., I.K.-G., M.M., J.G., K.S.-W.; visualization, S.V.L.; supervision, K.G.-B., G.Z., M.M. and K.S.-W.; project administration, S.V.L.; funding acquisition, K.G.-B., I.K.-G., K.S.-W.
