## Expanded Materials & Methods

### *Study population*

CoLaus is a population-based study in Caucasians 35-75 years old living in the city of Lausanne, Switzerland. At baseline (2003-2006), 6,189 participants were included. The design of the study has been described elsewhere(1). In this study, postmenopausal women from the baseline were included. The Institutional Ethics Committee of the University of Lausanne - Switzerland, approved CoLaus; written informed consent was obtained from all participants.

The Rotterdam Study (RS) is a population-based cohort study of individuals 45 years and over living in the Ommoord district of Rotterdam, the Netherlands. The rationale and design of RS is described elsewhere(2). In brief, at baseline (1990-1993), 7,983 participants aged 55 years and over were included (RS-I). In 2000, an additional 3011 participants 55+ years were enrolled (RS-II). A second extension of the cohort was initiated in 2006, in which 3,932 participants aged 45 years or older were included (RS-III). The present study includes data from postmenopausal women from the third visit of the first cohort of RS (RS-I-3), the first visits of the second (RS-II-1) and first visit of the third cohort (RS-III-1). The RS has been approved by the medical ethics committee according to the Population Study Act Rotterdam Study, executed by the Ministry of Health, Welfare and Sports of the Netherlands. A written informed consent was obtained from all participants.

### *Assessment of BP traits*

In CoLaus, BP was measured thrice on the left arm with an appropriately sized cuff, after at least 10-minutes rest in the seated position using an Omron® HEM-907 automated oscillometric sphygmomanometer. In RS, BP was measured twice on the right arm (cuff size of 32×17), after a resting period of 5-minutes rest in the seated position using a random-zero sphygmomanometer. In the UK Biobank BP was measured twice in a seated position after 2-minutes of rest using an Omron HEM-7015IT digital BP monitor and an appropriate cuff (3). SBP was recorded at the appearance of sounds (first-phase Korotkoff) and DBP at the disappearance of sounds (fifth-phase Korotkoff). In all cohorts, SBP and DBP were calculated as the average of two measurements, in CoLaus only the last two measurement were used. Also in CoLaus and RS, hypertension was defined as a SBP  $\geq 140$  mmHg, and/or DBP  $\geq 90$  mmHg, and/or the use of antihypertensive medication. Medication use information was based on the home interview in RS and self-filled questionnaires in CoLaus. Antihypertensive medication use was defined as diuretics,  $\beta$ -blockers, angiotensin-converting enzyme inhibitors, and calcium channel blockers. In the RS, a physician also ascertained the indication for which the medication had been prescribed.

### *Assessment of covariates*

Sociodemographic data, socio-economic, and lifestyle factors were recorded during the interview in both CoLaus and RS, and data from both studies were harmonized. Education was defined as low (primary education), intermediate (secondary general or vocational education), or high (higher vocational education or university). Alcohol intake was assessed in grams of ethanol per day, and participants were classified as drinkers vs. non-drinkers. Similarly, smoking status was dichotomized into current/ever smokers vs. never smokers. History of cardiovascular disease was defined as a history of coronary heart disease (myocardial infarction, revascularization, coronary artery bypass graft surgery or percutaneous coronary intervention) and was verified from the medical records of the general practitioner. Diabetes mellitus was defined as the use of blood glucose-lowering medications or fasting glucose  $\geq 7.0$  mmol/L. Estimated glomerular filtration rate (eGFR) was calculated using the simplified Modification of Diet in Renal Disease equation. Physical height (m) and body weight (kg) were measured at baseline with the participants standing without

shoes and heavy outer garments. Body mass index (BMI) was calculated as weight divided by height squared ( $\text{kg}/\text{m}^2$ ). All biochemical parameters were assessed in fasting serum.

#### *Genotyping*

In CoLaus, nuclear DNA was extracted from whole blood for whole genome scan analysis and genotyping was performed using the Affimetrix 500 K SNP chip, as recommended by the manufacturer. Subjects were excluded from the analysis in case of inconsistency between sex and genetic data, a genotype call rate <90%, or inconsistencies of genotyping results in duplicate samples. Quality control for SNPs was performed using the following criteria: monomorphic (or with minor allele frequency (MAF) <1%), call rates <90%, deviation from the Hardy-Weinberg equilibrium ( $p < 1 \times 10^{-6}$ ). Phased haplotypes were generated using SHAPEIT2(4). Imputation was performed using minimac3(5) and the Haplotype Reference Consortium (HRC version r1.1)(6) hosted on the Michigan Imputation Server(5).

In the RS, genotyping was conducted, in self-reported white participants, using the Illumina 550K array. Participants were excluded if they had excess autosomal heterozygosity, a mismatch between the reported and phenotypic sex, or recognized as being an outlier with identical-by-state clustering analysis. Moreover, SNPs with allele frequency  $\leq 1\%$ , Hardy-Weinberg equilibrium  $p < 10^{-5}$ , or SNP call rate  $\leq 90\%$  were excluded. Imputation was done with reference to HapMap release 22 CEU (Utah residents of northern and western European ancestry) using the maximum likelihood method implemented in Markov Chain based haplotype (version 1.0.15).

#### *Genetic risk score*

For each SNP included in the genetic risk score of the ANM (GRS-ANM), the number of corresponding coded alleles was multiplied by the absolute value of the beta-coefficient for ANM reported in the reference GWAS(7), and then these products were summed up. Successively, to produce an average measure, the GRS-ANM was divided by the number of effectively genotyped SNPs, then the product was multiplied by 100 to rescale the scores to a range between 0 and 100(8).

#### *Statistical Analyses*

##### *Cross-sectional analyses*

In the model 4 we calculated the variance inflation factor (VIF) to evaluate multicollinearity among the covariates included; none of them presented a value greater than 10 (9). We conducted the diagnostics of the final linear and logistic regression models by evaluating the residuals and we identified three observations with large leverage in the CoLaus data; these observations were excluded from the final model investigating the association between ANM and DBP. Interaction of ANM and BMI were evaluated in model 4 by including a cross-product interaction term. Furthermore, we fitted non-linear (spline) models, using the “mkspline” package with restricted cubic spline construction (4 knots) in Stata, to explore nonlinear relationship between ANM and SBP, DBP and hypertension. In CoLaus, ANM, eGFR and BMI were nonlinear in the logit scale, which is the link function where the probabilities of the levels of hypertension status are transform to a continuous scale to be modeled as a linear association between the exposures and the outcome. Therefore, fractional polynomial were explored; nevertheless, none of them improved the model. ANM, SBP and DBP did not follow a normal distribution; thus, a log transformation was tested (Table S2). However, results did not change and residuals followed the assumptions; as a result, the analysis were reported with the untransformed variables. To adjust for potential biases associated with missing data from the covariates, we used multiple imputation procedure (n=10 imputations) in the RS’s datasets; most of the variables had less than 7% of missing values, nevertheless alcohol consumption had up to 64% of missing values. Only two participants with missing data on BMI and

educational level were present in CoLaus study; thus, no multiple imputation was applied for analyses in CoLaus (Table S3).

#### *One sample Mendelian randomization*

##### *Association of the GRS-ANM and BP/ hypertension*

The first model adjusted for age and eGFR. In the second model, we additionally adjusted for antihypertensive medication, BMI, drinking status, diabetes, history of cardiovascular diseases, total cholesterol, smoking status, statin use, hormone therapy and education level; when hypertension was the outcome, we did not adjust for antihypertensive medications.

Mendelian randomization relies on three assumptions, first, the GRS-ANM is associated with the ANM, second, there are no unmeasured confounders of the association between GRS-ANM and BP traits, and third, the GRS-ANM affect the outcome only through their effect on the ANM(10). In order to explore the first assumption, we calculated the partial "F" statistics and partial "R<sup>2</sup>" for the association between GRS-ANM and ANM. Regarding the second and third assumption, we evaluated the association of each SNP with BP traits, and confounders. The cut-off for significance was established using the Bonferroni correction. To further investigate if a single SNP was influencing the associations, we performed a leave-one-out analysis by creating GRSs that excluded one SNP at a time(11).

#### *Two sample Mendelian Randomization*

IVM assumes that all variants are valid instruments, and any pleiotropy is balanced. The MR-Egger was implemented under the Instrument Strength Independent of Direct Effect (InSIDE) assumption, the intercept of a weighted regression will be other than zero in the existence of directional pleiotropy, and the slope of that regression will be a consistent estimate of the causal effect of X on Y. The weighted median method is robust to outliers (up to 50% of invalid instrumental variables), while MR-PRESSO addresses the between variants heterogeneity and horizontal pleiotropy(11).

#### *Author contributions*

TM conceived the study. ZMRD, EA, PMV, TV and TM designed the study. TM supervised the study. ZMRV, EA, HA, LZR, JN, MAI, FD, OHF, RP, PDM, TV and TM participated in data acquisition, collection, analysis or interpretation. ZMRD, EA, HA, FD and RP performed the statistical analyses. ZMRD, EA, PMV, TV and TM drafted the manuscript; HA, LZR, JN, MAI, FD, OHF, and RP critically revised the manuscript for intellectual content. All authors approved the final version of the manuscript. ZMRD and TM are the guarantors of the study and responsible for the integrity of the work as a whole.

\* From 39 Damage DNA repair SNPs were identified in the reference GWAS of age at natural menopause Day et al. Clumping the identified SNPs just 29 SNPs were identified as independent and included in the analyses.

\*\* From 17 Non-Damage DNA repair SNPs were identified in the reference GWAS of age at natural menopause Day et al. The 17 SNPs were classified as independent SNPs after the implementation of the function clump in the two MR package.

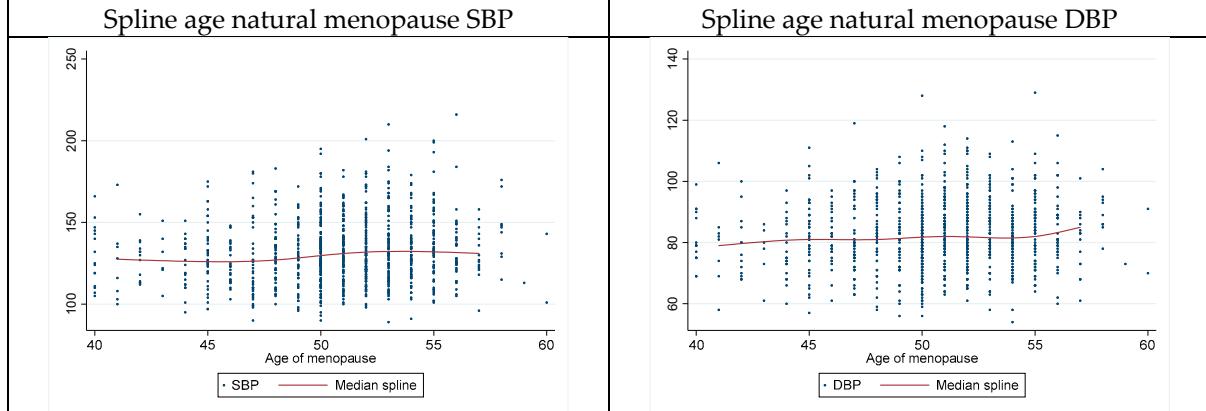

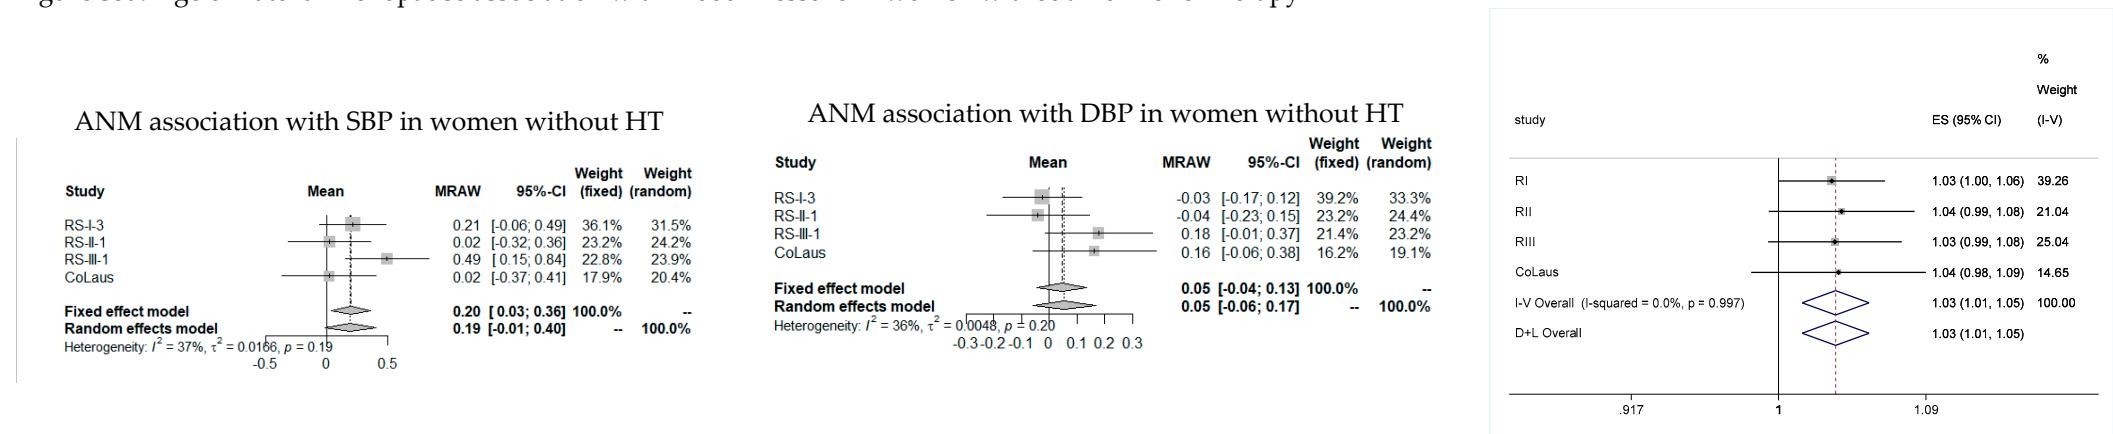

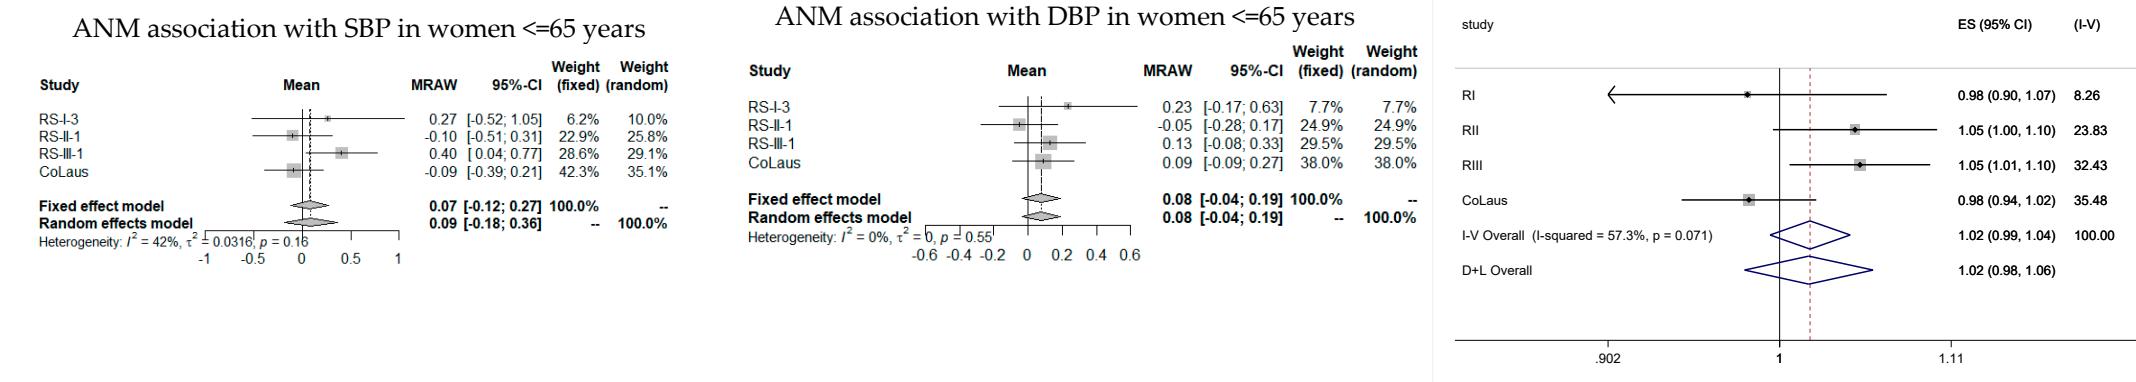

FIGURE S3. SENSITIVITY ANALYSIS OBSERVATIONAL ASSOCIATION ANM AND BLOOD PRESSURE TRAITS

Figure S3a. Age of natural menopause association with Blood Pressure in women without Hormone Therapy

RS-I-3 n= 1466; RS-II-1 n= 759; RS-III-1 n= 898; CoLaus n= 499. 827 observations deleted which include missing values and women who reported the use of hormone replacement therapy. Regressions by study were not adjusted by Hormone replacement therapy.

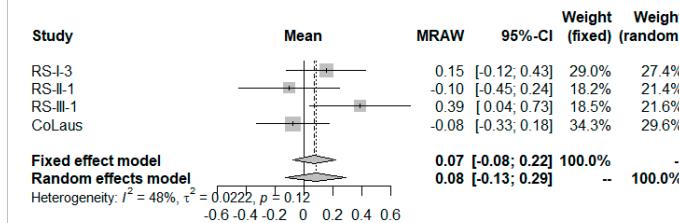

Figure S3b. Age of natural menopause association with Blood Pressure traits in women aged 65 years and younger.

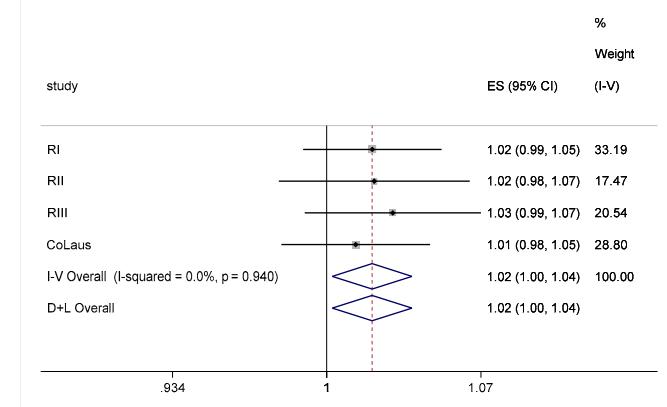

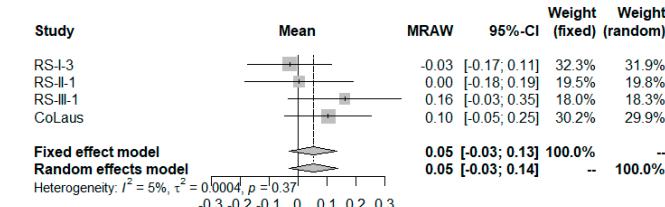

RS-I-3 n= 235; RS-II-1 n= 518; RS-III-1 n=826; CoLaus n=818. 2,052 observations deleted which include women older than 65 years old. Regressions by study were fully adjusted.

Figure S3c. Age of natural menopause association with Blood Pressure traits in women without history of cardiovascular diseases.

ANM association with SBP in women without history of CVD

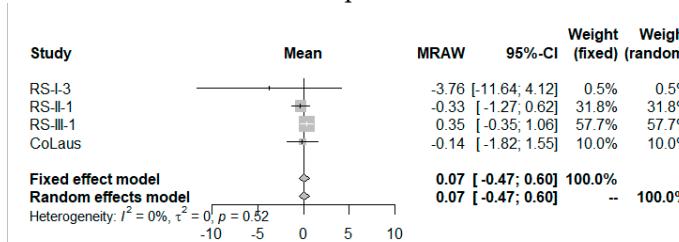

ANM association with DBP in women without history of CVD

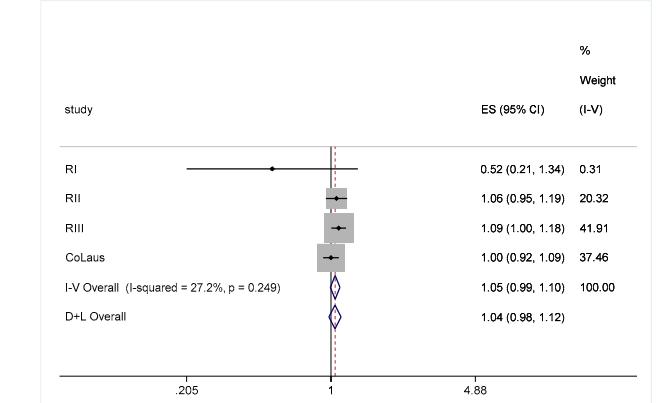

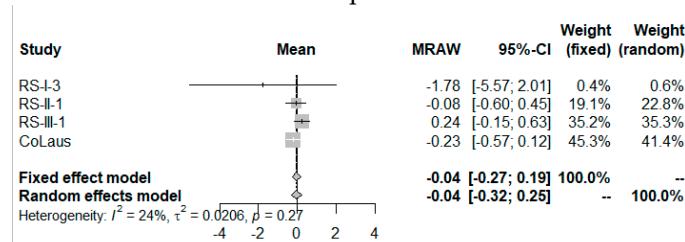

RS-I-3 n=1414; RS-II-1 n=746; RS-III-1 n=887; CoLaus n=1052. 350 observations deleted which include women who reported history of cardiovascular diseases and missing values. Regressions by study were not adjusted by history of cardiovascular diseases.

Figure S3d. Age of natural menopause association with Blood Pressure traits in Women with maximum 10 years after menopause

ANM association with SBP in women <=10 years menopause

ANM association with DBP in women <=10 years menopause

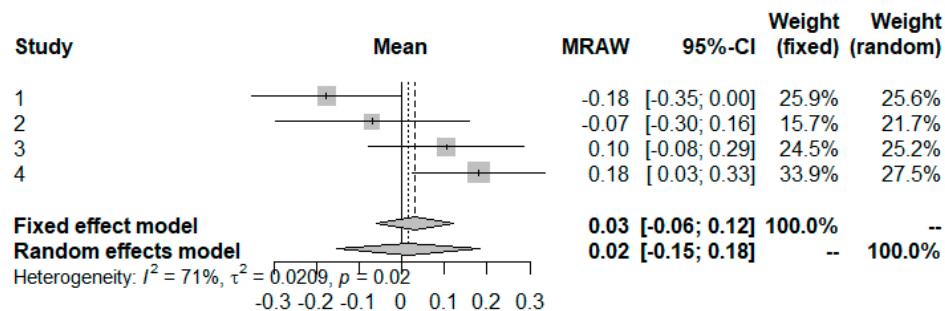

RS-I-3 n=51; RS-II-1 n=312; RS-III-1 n=611; CoLaus n=570. 2,905 observations deleted which include missing values and women who reported experiencing menopause more than 10 years ago

Regressions by study were fully adjusted

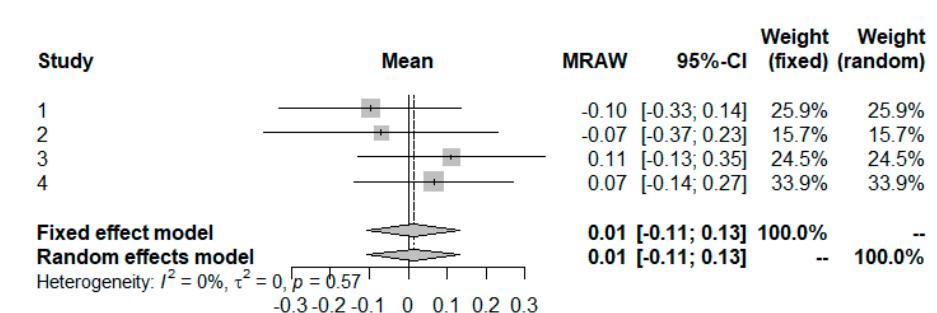

Use of antihypertensive medication was excluded from the HTA regressions

Figure S3e. Age of natural menopause association with Blood Pressure traits in Women without hypertension.

ANM association with DBP in women without hypertension

ANN association with SBP in women without hypertension

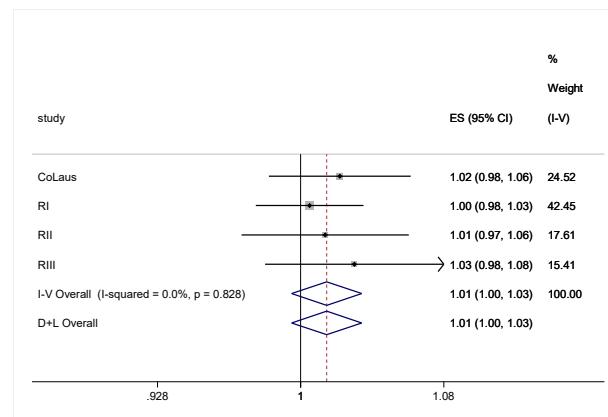

Study 1: RS-I-3 n=493; Study 2: RS-II-1 n=298; Study 3: RS-III-1 n=465; Study 4: CoLaus n=645. 2,548 women who had hypertension were deleted

Regressions by study were fully adjusted

Use of antihypertensive medication was excluded

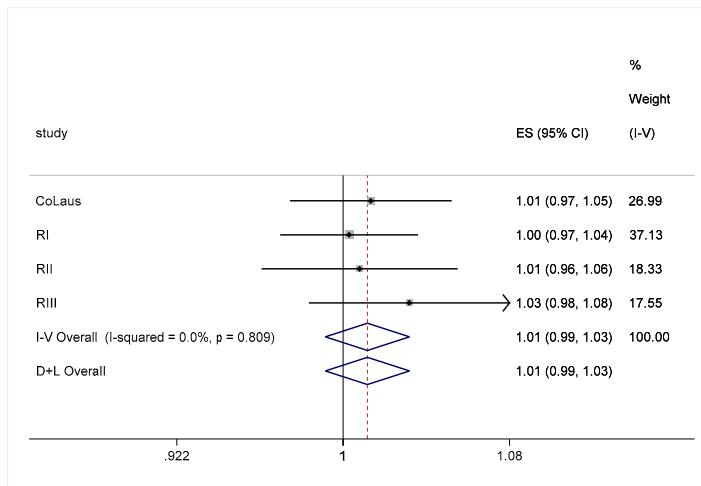

Pooled analysis regressions were adjusted by cohort

Figure S3f. Age of natural menopause association with hypertension defined antihypertensive medication

Prevalence of hypertension defined as antihypertensive medication CoLaus n=262(23.0); RS-I-3 n=614(38.3); RS-II-1 n=226(28.6); RS-III-1 n=223(24.2)

Figure S3g. Age of natural menopause association with hypertension defined antihypertensive medication in women with estimated glomerular filtration rate smaller than 60 ml/min/1.73m<sup>2</sup>

Study 1:RS-I-3 n= 1,237; Study 2: RS-II-1 n= 708; Study 3: RS-III-1 n= 878; Study 4: CoLaus n= 1,033; 593 observations deleted

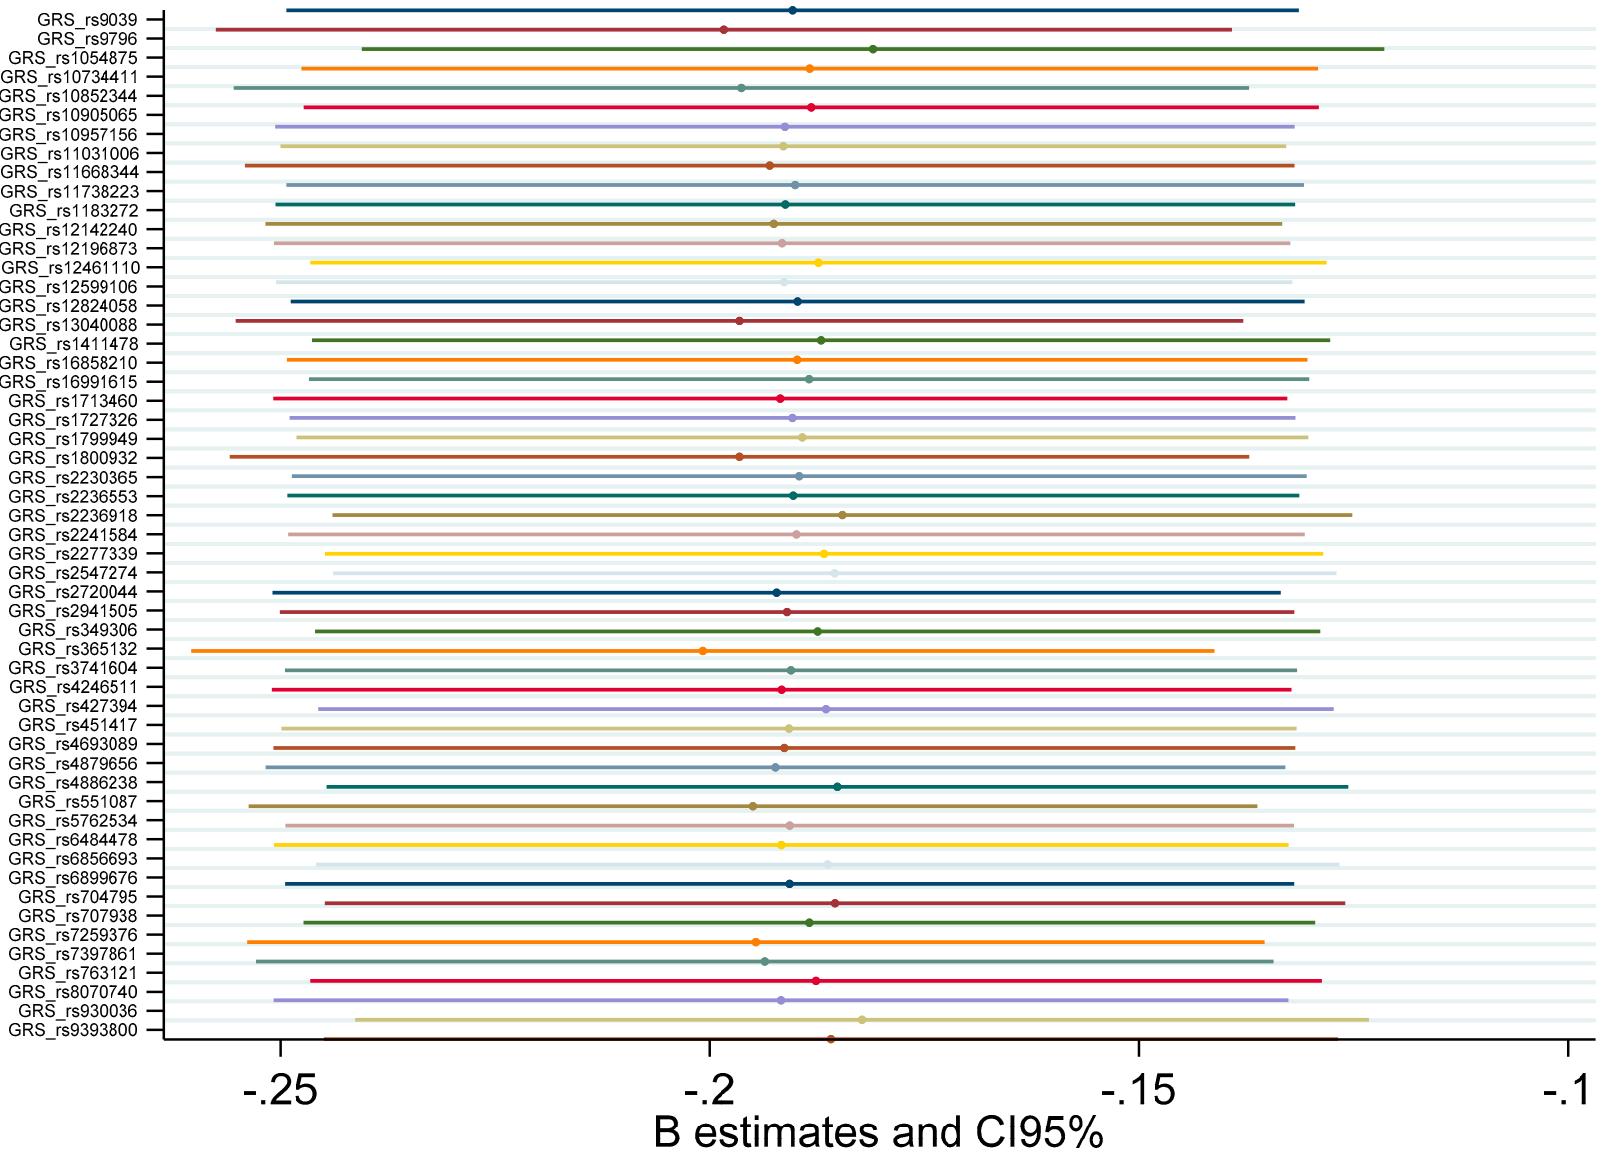

Regressions by study were fully adjusted
