Figure S1. Cyclic Voltammograms obtained by 1 V step increment in the voltage up to a maximum of (a) 7 V for mirror polished Ti-6Al-4V alloy surface. (b) Thickness estimation of anodized oxide layer formed on polished Ti-6Al-4V alloy surface after each increment in the voltage. The oxidation of the surface starts at a voltage E_{SHE} of about 1.2 V, which is accompanied by excessive O_2 evolution for voltages of about $E_{\text{SHE}} = 4.3$ V and higher. This figure adapted from [1] (see below).

Figure S2. Pre-anodized Bone Implants: Commercially available Ti-based bone screws and bone plates from the product line of Hofer GmbH & Co KG (Fürstenfeld, Austria, <https://www.hofer-medical.com/>). (a) Screws that show an intensive blue color due to pre-anodization, as most of the screws used in our experiments; (b) Blue and gold colored screws, screwed into a bone plate, that were pre-anodized under two different conditions.

Figure S3. Collagen Type I Immunostaining: Fluorescence microscope images of osteoblasts on laser-structured and/or anodized Ti-6Al-4V alloy samples stained against collagen Type I. Bright color corresponds to high fluorescence. The blue lines are the border between areas which were femtosecond laser-processed and sub-sequently anodized (laser + anod.) and areas which were anodized (anod.), respectively. Figures (a) and (b) show the results from two different samples.
