Fig. S5 Nucleotides sequences of the FLIP-H₂O₂ sensor

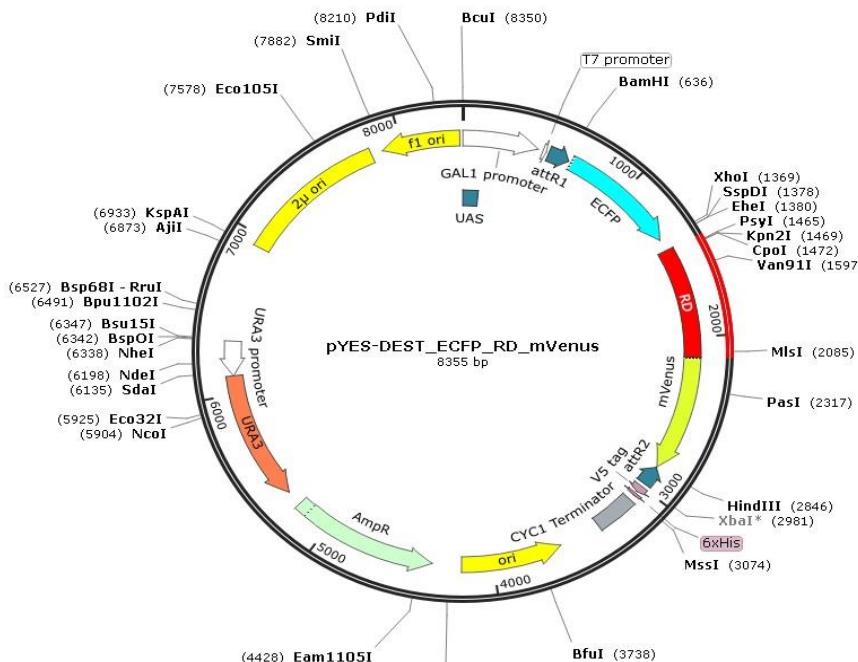

Fig. S6 Schematic representation of pYES-DEST-ECFP-RD-mVenus

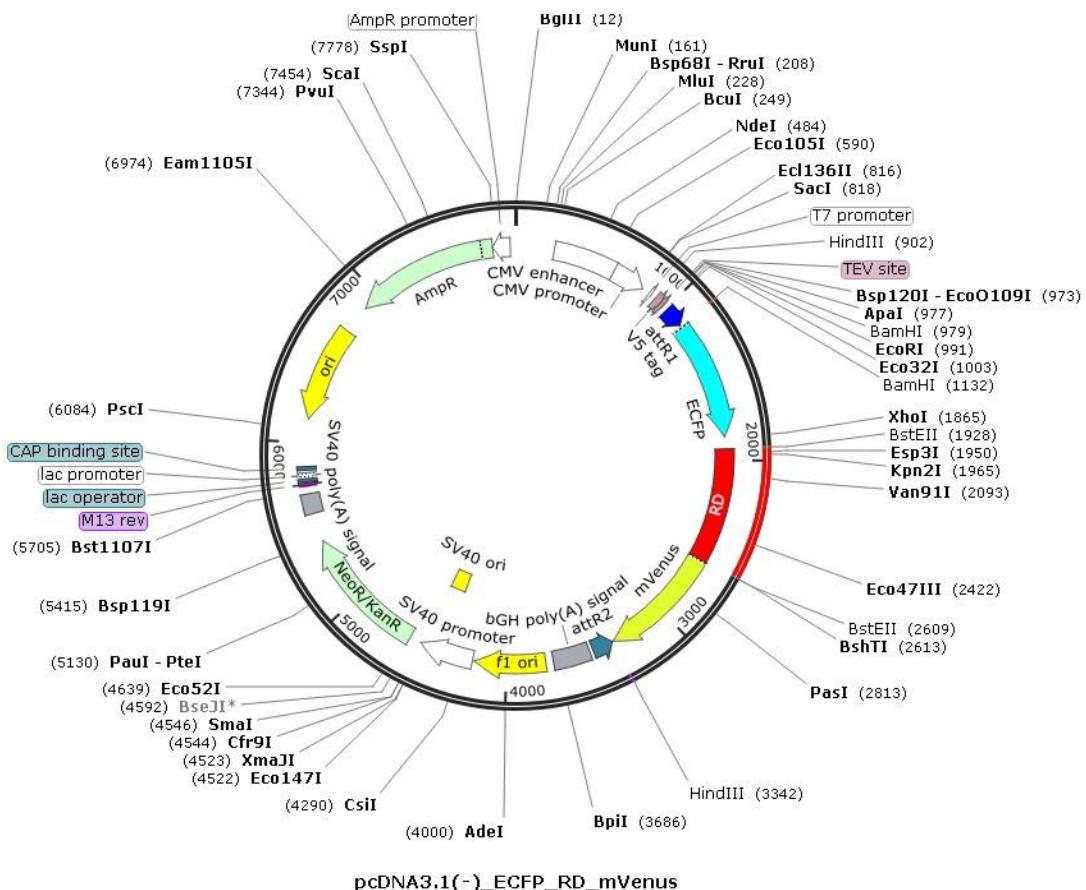

Fig. S7 Schematic representation of pcDNA 3.1(-)-ECFP-RD-mVenus

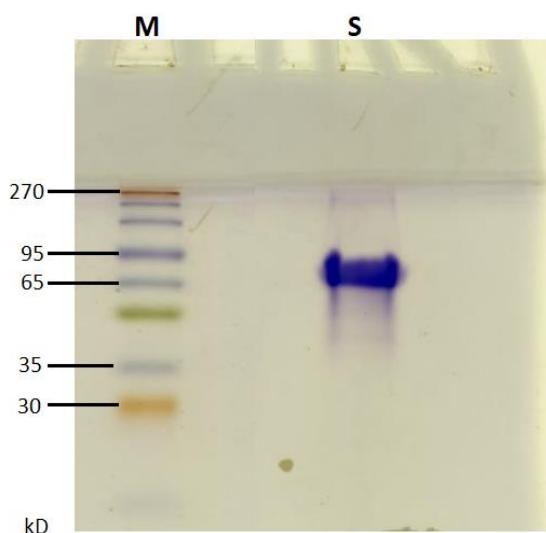

Fig. S8 Purified ECFP-RD-mVenus protein was resolved on 12% SDS-PAGE. Expected band was observed (M-marker, S-purified protein ~80 kD)

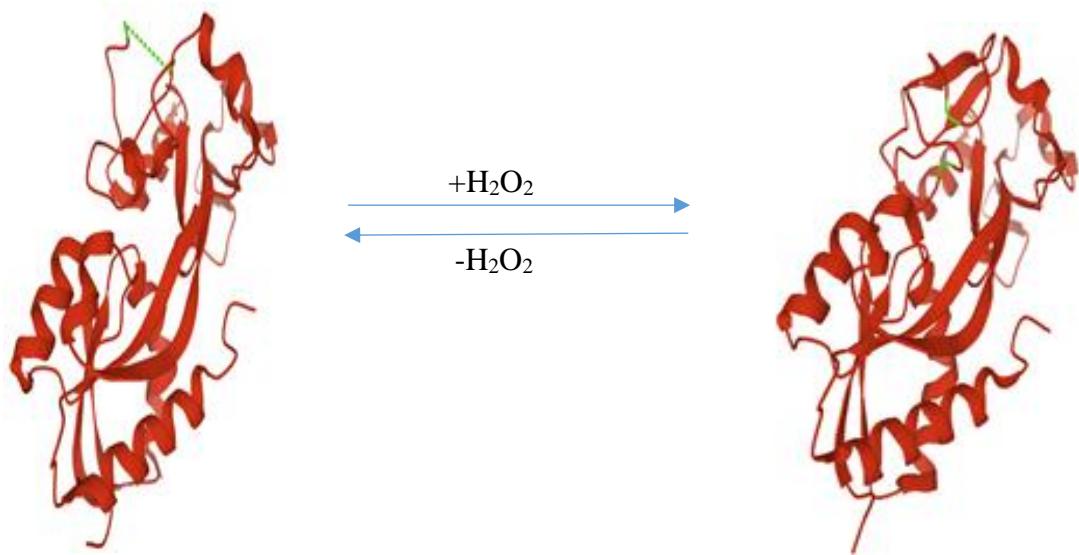

Fig. S9 Reduced and oxidized form of RD and H_2O_2 induced conformational changes in the domain.

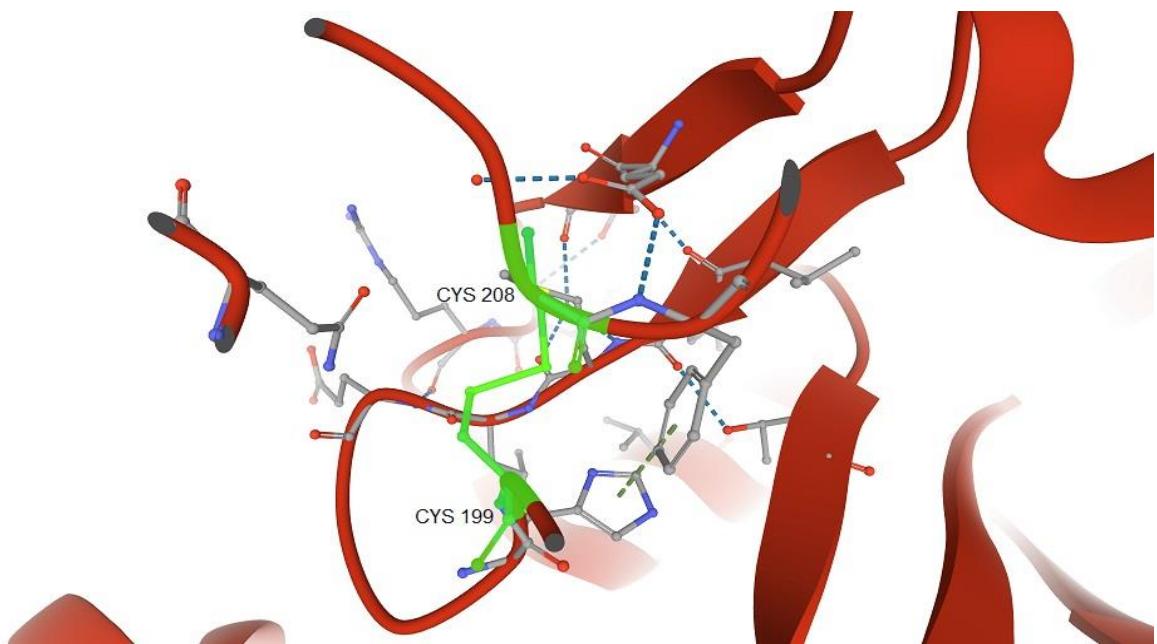

Fig. S10 Close-up structure of critical cysteine residues of regulatory domain involved in H_2O_2 sensing.

Supplementary table. S1 Comparison of various H₂O₂ detection approaches and their properties.

Sensor/ Probe name	Advantages	Disadvantages	Kd	Linear detection range (μ M)	References
Luminol Chemiluminescent Probe	High signal-to background ratio, Spectral properties can be easily adjusted.	Temperature dependency, Irreversible, Reaction dependent interferences (e.g., Ag(I), Cu(II), Co(II), Fe(II), pH, ROS, hydroperoxides).	Not reported	1-100	[27]
RPF1	Ratiometric fluorescence reporter, minimize damage and autofluorescence from biological samples	difficult to deliver into living cells and causes the toxicity, not rapid response to peroxide	Not reported	5-200	[12]
Dichlorodihydrofluorescein diacetate (DCFH-DA)	cell-permeable	DCFH does not directly react with H ₂ O ₂ , can actually produce O ₂ [•]	Not reported	1-50	[9]
roGFP	Dynamic changes can be monitored, Reversible reaction	Single fluorophore based Approach, low dynamic range prone to photobleaching.	Not defined	10-1000	[28]
Hyper	Dynamic changes can be monitored, Reversible reaction, Can be targeted to specific subcellular compartments	Highly sensitive to pH changes	Sub- micromolar	0.2-10	[15]
