# Antimicrobial Peptides of Salmonid Fish: From Form to Function

Sascha R. Brunner, Joseph F. A. Varga, and Brian Dixon

**Figure S1.** Phylogenetic tree of published salmonid cathelicidins. Cathelicidins form two well-supported clades within salmonids. The tree was constructed on exon 1-3 as exon 4 is highly variable. All analysis was done in R v3.6.1 (The R Core Team 2020). Amino acid sequences were retrieved from GenBank and aligned using ClustalW. A pairwise distance matrix was constructed with the pairwise deletion option selected. The tree was constructed with the improved neighbour-joining method BIONJ [1]. The tree is rooted with 3 mammalian and 2 agnatha sequences. Root nodes indicate bootstrap values (1000 replicates) in percent.

**Figure S2.** Phylogenetic tree of published and predicted salmonid hepcidins. Hepcidins form one clade within salmonids. For analysis details, see description of Figure S1. Amino acid sequences were retrieved from GenBank. The tree is rooted with 3 mammalian sequences. Root nodes indicate bootstrap values (1000 replicates) in percent.

**Table S1.** Salmonid Antimicrobial Peptides from Databases.
