English Article HPV; Mathematical model; Cost-effectiveness; Extended Middle East; North Africa HUMAN-PAPILLOMAVIRUS; HPV VACCINE; MATHEMATICAL-MODELS; ECONOMIC-IMPACT; LATIN-AMERICA; HEALTH; KNOWLEDGE; AWARENESS; STUDENTS; WOMEN To date, no studies have evaluated the cost-effectiveness of human papillomavirus (HPV) vaccination in countries in the Extended Middle East and North Africa (EMENA) region. We synthesized population and epidemiologic data for 20 EMENA countries using a model-based approach to estimate averted cervical cancer cases and deaths, disability-adjusted life years (DALYs) and cost-effectiveness ratios (I\$ [international dollars] per DALY averted) associated with HPV vaccination of pre-adolescent girls. We utilized additional epidemiologic data from Algeria, Lebanon, and Turkey to evaluate select cervical cancer screening strategies either alone or in combination with vaccination. Results showed that pre-adolescent vaccination of five consecutive birth cohorts at 70% coverage has the potential to prevent over 180,000 cervical cancer cases. Cases averted varied by country, largely due to differences in cancer burden and population size; 69% of cases averted occurred in the three GAVI-eligible countries in EMENA. Despite the low cervical cancer incidence in EMENA, we found that HPV vaccination was cost-effective using a threshold of each country's gross domestic product per capita (a common metric for evaluating cost-effectiveness) in all but five countries at a cost per vaccinated girl of I\$25 (\$5 per dose). However, cost-effectiveness diminished with increasing vaccine cost; at a cost of I\$200 per vaccinated girl, HPV vaccination was cost-effective in only five countries. When the cost per vaccinated girl exceeded I\$50 in Lebanon and Turkey and I\$150 in Algeria, screening alone was most attractive. We identified opportunities to improve upon current national screening guidelines, involving less frequent screening every 3-5 years. While pre-adolescent HPV vaccination promises to be a cost-effective strategy in most EMENA countries at low costs, decision makers will need to consider many other factors, such as affordability, acceptability, feasibility, and competing health priorities, when making decisions about cervical cancer prevention. This article forms part of a regional report entitled "Comprehensive Control of HPV Infections and Related Diseases in the Extended Middle East and North Africa Region" Vaccine Volume 31, Supplement 6, 2013. Updates of the progress in the field are presented in a separate monograph entitled "Comprehensive Control of HPV Infections and Related Diseases" Vaccine Volume 30, Supplement 5, 2012. Knowledge and Perceptions of Greek Students about Human Papilloma Virus, Vaccination and Cervical Cancer Screening CHILDREN-BASEL English

Article

health literacy;

youth; adolescents; cervical cancer; vaccination UNIVERSITY-

STUDENTS; NURSING-STUDENTS; HPV INFECTION; ACCEPTANCE; AWARENESS;

PREVENTION; BELIEFS; RISK INTRODUCTION: Human papillomavirus (HPV) is the main cause of cervical cancer; the level of HPV-related knowledge among young students remains however questionable. The purpose of the present study was to investigate knowledge pertaining to HPV, cervical cancer screening, and vaccination among students in the Nursing Department and Department of Social Work of the Hellenic Mediterranean University of Crete, Greece. METHODS: This was a questionnaire-based, cross-sectional study involving 371 first-year and third-year students of the two Departments. Multivariate linear and logistic regression analysis was performed to examine factors associated with knowledge related to HPV, cervical cancer screening, and HPV vaccination. RESULTS: Only 22.1% of students knew all the ways of HPV transmission and only 5.9% knew the whole spectrum of cancers that HPV could cause. The vaccination rate for HPV was 33.7%. The majority of students used the Internet as the main source of information (62.3%). Students' sociodemographic characteristics, including age, marital status, and Department of studies were associated with knowledge about HPV. CONCLUSIONS: The present study highlights knowledge gaps and indicates the need for thorough health education strategies on HPV, targeting families and young people.

Comparative predictors for cervical cancer screening in Southeast Michigan for Middle Eastern-North African (MENA), White and African American/black women PREVENTIVE MEDICINE

English Article

Middle East-North African (MENA); Health disparities; cancer screening; Cervical cancer screening; Female; Religion ARAB AMERICANS; ASSOCIATION; BREAST; BLACK The cervical cancer screening behaviors of Arab American women are not adequately understood, in part because Middle Eastern North African (MENA)

descent is not a US Census category. Others have shown decreased cervical cancer screening in this race of women. Our primary aim is to evaluate the predictors of cervical cancer screening among MENA, White and Black women of southeast Michigan. A community-wide health survey reached MENA, White and Black populations asking self-report questions about health behaviors, attitudes, and medical history. Cervical cancer screening was considered up-to-date if it was reported to have occurred within the past three years. Survey responses were limited to women 30-65 years old and were analyzed with inferential and logistic regression models to determine risk factors for cervical cancer screening. Overall, 78% reported cervical cancer screening within the past three years. MENA women screened less often if time in the US was less than ten years (aOR 0.24 (0.05, 0.76)) compared to more than ten years and if single (aOR 0.27 (0.07, 0.97)) compared to married. Religion was not associated with screening in any study population. Those of all races without insurance screened significantly less often than those with insurance. The barriers to cervical cancer screening among MENA women are not associated with religion but instead with lack of insurance and length of time residing in the US. Minal R.; Resnicow, Ken Predictors of screening

for cervical and colorectal cancer in women 50-65 years old in a
multi-ethnic population PREVENTIVE MEDICINE REPORTS

English Article Cervical
cancer screening; Colorectal cancer screening; Females; 50-65
years old; Middle Eastern-North American (MENA); ethnicity

UNITED-STATES; MEN; ADHERENCE Middle Eastern/North
Africa (MENA) women are often not identified in cancer screening
studies. The aim of this study was to determine the rates and
predictors of cervical and colorectal cancer (CRC) screening for
women 50-65 years of three race/ethnicities. White, black and MENA
women of Southeast Michigan were surveyed once in 2019 for
demographics, health care barriers, chronic diseases, and cancer
screening updates using in-person, telephone, and online methods.
Descriptive statistics and multivariate multinomial logistic
regression were used to predict up-to-date colorectal cancer and
cervical cancer screening. All analyses were adjusted by local
population weights for comparability and generalizability. 394
women participated with 54% up-to-date on both screenings, 21% for
cervical cancer screening alone, and 12% for CRC alone. Women more
likely to be up-to-date for only cervical cancer screening
compared to both cancer screens are younger (aOR 0.83 (95% CI
0.76, 0.92), are of MENA descent (7.97 (2.46, 25.76) and have no
insurance (9.41 (1.07, 82.92)). There are no predictors for women
being up-to-date for CRC screening alone compared to both screens.
Among women 50-65 years old, being up-to-date in cervical cancer
screening is unrelated to being up-to-date for CRC screening.
Compared to Healthy People 2020, there are significant gaps in
cervical and CRC screening among women 50-65 years old of all
races, but particularly among women of MENA descent who are even
less likely to have CRC screening than cervical cancer screening.

Decreasing Disparities in Breast Cancer Screening in Refugee
Women Using Culturally Tailored Patient Navigation JOURNAL OF
GENERAL INTERNAL MEDICINE English Article

breast cancer screening; patient
navigation; vulnerable populations; disparities HEALTH-CARE;
BARRIERS; COMMUNITY; KNOWLEDGE; ATTITUDES; UPDATE; STATE Patient
navigator (PN) programs can improve breast cancer screening in low
income, ethnic/racial minorities. Refugee women have low breast
cancer screening rates, but it has not been shown that PN is
similarly effective. Evaluate whether a PN program for refugee
women decreases disparities in breast cancer screening.
Retrospective program evaluation of an implemented intervention.
Women who self-identified as speaking Somali, Arabic, or Serbo-
Croatian (Bosnian) and were eligible for breast cancer screening
at an urban community health center (HC). Comparison groups were
English-speaking and Spanish-speaking women eligible for breast
cancer screening in the same HC. Patient navigators educated women
about breast cancer screening, explored barriers to screening, and
tailored interventions individually to help complete screening.
Adjusted 2-year mammography rates from logistic regression models
for each calendar year accounting for clustering by primary care
physician. Rates in refugee women were compared to English-
speaking and Spanish-speaking women in the year before
implementation of the PN program and over its first 3 years. There
were 188 refugee (36 Somali, 48 Arabic, 104 Serbo-Croatian
speaking), 2,072 English-speaking, and 2,014 Spanish-speaking
women eligible for breast cancer screening over the 4-year study
period. In the year prior to implementation of the program,
adjusted mammography rates were lower among refugee women (64.1 %, 95 % CI: 49-77 %) compared to English-speaking (76.5 %, 95 % CI: 69 %-83 %) and Spanish-speaking (85.2 %, 95 % CI: 79 %-90 %) women. By the end of 2011, screening rates increased in refugee women (81.2 %, 95 % CI: 72 %-88 %), and were similar to the rates

in English-speaking (80.0 %, 95 % CI: 73 %-86 %) and Spanish-speaking (87.6 %, 95 % CI: 82 %-91 %) women. PN increased screening rates in both younger and older refugee women. Linguistically and culturally tailored PN decreased disparities over time in breast cancer screening among female refugees from Somalia, the Middle East and Bosnia. Cancer risk perception and physician communication behaviors on cervical cancer and colorectal cancer screening ELIFE

English Article

WOMEN; RECOMMENDATION; ADHERENCE; AMERICANS; FATALISM; ARAB

Background: Women 50-65 years of age have the lowest cervical and colorectal cancer (CRC) screening rates among ages recommended for screening. The primary aim of this work is to determine how cancer risk perceptions and provider communication behaviors, in addition to known demographic factors, influence the uptake of both cervical and CRC screening or a single screen among women in southeast Michigan. Methods: Fourteen health services and communication behavior questions were adapted from the Health Information National Trends Survey (HINTS) and administered to a

multiethnic sample of adults in southeast Michigan. The outcome variable was self-reported up-to-date cervical cancer and/or CRC screening as defined by the United States Preventive Services Task Force (USPSTF). Demographic and cancer risk/communication behavior responses of the four screening populations (both tests, one test, no tests) were analyzed with multinomial regression for all comparisons. Results: Of the 394 respondents, 54% were up to date for both cervical and CRC screening, 21% were up to date with only cervical cancer screening and 12% were up to date for only CRC screening. Of the 14 risk perception and communication behavior questions, only 'Did your primary care physician (PCP) involve you in the decisions about your health care as much as you wanted?' was significantly associated with women having both screens compared to only cervical cancer screening (aOR 1.67; 95% CI: 1.08, 2.57). The multivariate model showed age, and Middle East and North African (MENA) ethnicity and Black race, in addition to PCP-patient dyad decision-making to be associated with the cancer screenings women completed. Conclusions: Optimizing PCP-patient decision-making in health care may increase opportunities for both cervical cancer and CRC screening either in the office or by self-sampling. Understanding the effects of age and the different interventional strategies needed for MENA women compared to Black women will inform future intervention trials aimed to increase both cancer screenings.

J Sharma, M; Seoud, M; Kim, JJ Sharma,
Monisha; Seoud, Muhieddine; Kim, Jane J. Cost-
effectiveness of increasing cervical cancer screening coverage in
the Middle East: An example from Lebanon VACCINE
English Article Cervical
cancer; Screening; Middle East; Lebanon; Cost-effectiveness;
Modeling HUMAN-PAPILLOMAVIRUS VACCINATION; HPV-18 VACCINATION;
EPIDEMIOLOGY; PREVENTION; CAREHPV; IMPACT; MODEL Background:
Most cervical cancer (CC) cases in Lebanon are detected at later
stages and associated with high mortality. There is no national
organized CC screening program so screening is opportunistic and
limited to women who can pay out-of-pocket. Therefore, a small
percentage of women receive repeated screenings while most are
under-or never screened. We evaluated the cost-effectiveness of
increasing screening coverage and extending intervals. Methods: We
used an individual-based Monte Carlo model simulating HPV and CC
natural history and screening. We calibrated the model to
epidemiological data from Lebanon, including CC incidence and HPV
type distribution. We evaluated cytology and HPV DNA screening for
women aged 25-65 years, varying coverage from 20 to 70% and
frequency from 1 to 5 years. Results: At 20% coverage, annual
cytologic screening reduced lifetime CC risk by 14% and had an
incremental cost-effectiveness ratio of 1\$80,670/year of life
saved (YLS), far exceeding Lebanon's gross domestic product (GDP)
per capita (1\$17,460), a commonly cited cost-effectiveness
threshold. By comparison, increasing cytologic screening coverage
to 50% and extending screening intervals to 3 and 5 years provided
greater CC reduction (26.1% and 21.4, respectively) at lower costs
compared to 20% coverage with annual screening. Screening every 5
years with HPV DNA testing at 50% coverage provided greater CC
reductions than cytology at the same frequency (23.4%) and was
cost-effective assuming a cost of 1518 per HPV test administered
(1\$12,210/YLS); HPV DNA testing every 4 years at 50% coverage was
also cost-effective at the same cost per test (1\$16,340).
Increasing coverage of annual cytology was not found to be cost-
effective. Conclusion: Current practice of repeated cytology in a
small percentage of women is inefficient. Increasing coverage to
50% with extended screening intervals provides greater health
benefits at a reasonable cost and can more equitably distribute
health gains. Novel HPV DNA strategies offer greater CC reductions
and may be more cost-effective than cytology. (C) 2016 Elsevier

Prevalence and

patterns of mutations in RAS/RAF/MEK/ERK/MAPK signaling pathway in colorectal cancer in North Africa BMC CANCER English

Article

KRAS; NRAS; And BRAF

mutations; Colorectal cancer; Lifestyle factors; North Africa RAS P21 ONCOPROTEIN; K-RAS; FUSOBACTERIUM-NUCLEATUM; MOROCCAN PATIENTS; KRAS MUTATIONS; BRAF; GENE; CARCINOGENESIS; POPULATION; OVEREXPRESSION Background Our review discuss (i) the findings from analyzed data that have examined KRAS, NRAS and BRAF mutations in patients with colorectal cancer (CRC) in North Africa and to compare its prevalence with that shown in other populations and (ii) the possible role of dietary and lifestyle factors with CRC risk. Methods Using electronic databases, a systematic literature search was performed for the KRAS, NRAS, and BRAF mutations in CRC patients from Morocco, Tunisia, Algeria and Lybia. Results Seventeen studies were identified through electronic searches with six studies conducted in Morocco, eight in Tunisia, two in Algeria, and one in Libya. A total of 1843 CRC patients were included 576 (31.3%) in Morocco, 641 (34.8%) in Tunisia, 592 (32.1%) in Algeria, and 34 (1.8%) in Libya. Overall, the average age of patients was 52.7 years old. Patients were predominantly male (56.6%). The mutation rates of KRAS, NRAS and BRAF were 46.4%, 3.2% and 3.5% of all patients, respectively. A

broad range of reported KRAS mutation frequencies have been reported in North Africa countries. The KRAS mutation frequency was 23.9% to 51% in Morocco, 23.1% to 68.2% in Tunisia, 31.4% to 50% in Algeria, and 38.2% in Libya. The G12D was the most frequently identified KRAS exon 2 mutations (31.6%), followed by G12V (25.4%), G13D (15.5%), G12C (10.2%), G12A (6.9%), and G12S (6.4%). G12R, G13V, G13C and G13R are less than 5%. There are important differences among North Africa countries. In Morocco and Tunisia, there is a higher prevalence of G12D mutation in KRAS exon 2 (approximate to 50%). The most frequently mutation type in KRAS exon 3 was Q61L (40%). A59T and Q61E mutations were also found. In KRAS exon 4, the most common mutation was A146T (50%), followed by K117N (33.3%), A146P (8.3%) and A146V (8.3%).

Conclusion KRAS mutated CRC patients in North Africa have been identified with incidence closer to the European figures. Beside established anti-CRC treatment, better understanding of the causality of CRC can be established by combining epidemiology and genetic/epigenetic on CRC etiology. This approach may be able to significantly reduce the burden of CRC in North Africa. STAT3 polymorphisms in North Africa and its implication in breast cancer
MOLECULAR GENETICS & GENOMIC MEDICINE
English Article

breast cancer; miR-3606-5p; North Africa; rs7211777; STAT3
SIGNAL-TRANSDUCER; TRANSCRIPTION FACTORS; GENE
POLYMORPHISMS; PROSTATE-CANCER; ASSOCIATION; ACTIVATOR;
INFLAMMATION; EXPRESSION; ROLES; CELLS Background Only a few studies have investigated the association of single nucleotide polymorphisms in STAT3 gene with the susceptibility to cancer and response to chemotherapy. Our aim was to determine the allele frequencies of rs3869550, rs957971, and rs7211777 at the STAT3 gene in North African populations and compare them to 1000 genomes populations, and to investigate their relation with cancer. Methods The targeted SNPs have been analyzed in six Tunisian populations and a sample of Libyans using TaqMan (R) Assay. The results were compared to 1000 Genomes Project population samples. Targeting of the regions encompassing the three SNPs by micro-ARN was assessed using miR databases. Results The analysis of the 3 SNPs showed that North African populations were close to South Asians. As expected, African populations presented a significant frequency of the ancestral CCG haplotype in contrast to other populations where the fully derived TGA haplotype was more frequent. The presence and diversity of rare haplotypes at STAT3 in North African populations could have been generated by recombination between the two major haplotypes. A screening of the micro-RNA databases showed that the STAT3 region with the mutated allele of rs7211777 (G>A) could be targeted by miR hsa-miR-3606-5p, which also targets genes involved in breast cancer. Mediterranean diet
and colorectal cancer risk: results from a European cohort

EUROPEAN JOURNAL OF EPIDEMIOLOGY

English

Article

Mediterranean diet;

Colorectal cancer; Cohort study PHYSICAL-ACTIVITY; RECTAL
CANCERS; EPIC COHORT; NUTRITION; ADHERENCE; PATTERNS; SURVIVAL;
HEALTH; METAANALYSIS; POPULATION The authors investigated the
association of adherence to Mediterranean diet with colorectal
cancer (CRC) risk in the European Prospective Investigation into
Cancer and nutrition study. Adherence to Mediterranean diet was
expressed through two 10-unit scales, the Modified Mediterranean
diet score (MMDS) and the Centre-Specific MMDS (CSMMDS). Both
scales share the same dietary components but differ in the cut-off
values that were used for these components in the construction of
the scales. Adjusted hazard ratios (HR) for the associations of
these scales with CRC incidence were estimated. After 5,296,617
person-years of follow-up, 4,355 incident CRC cases were
identified. A decreased risk of CRC, of 8 and 11 % was estimated
when comparing the highest (scores 6-9) with the lowest (scores 0-
3) adherence to CSMMDS and MMDS respectively. For MMDS the HR was
0.89 (95 % confidence interval (CI): 0.80, 0.99). A 2-unit
increment in either Mediterranean scale was associated with a
borderline statistically significant 3 to 4 % reduction in CRC
risk (HR for MMDS: 0.96; 95 % CI: 0.92, 1.00). These associations
were somewhat more evident, among women, were mainly manifested
for colon cancer risk and their magnitude was not altered when
alcohol was excluded from MMDS. These findings suggest that
following a Mediterranean diet may have a modest beneficial effect
on CRC risk. [Bamia, Christina; Lagiou, Pagona; Trichopoulou,

J Gereige, JD; Zhang, L; Boehmer, U Gereige,
Jessica D.; Zhang, Li; Boehmer, Ulrike The Sexual
Health of Women in Lebanon: Are There Differences by Sexual
Orientation? LGBT HEALTH English Article
access to care; cervical cancer
screening; female homosexuality; Middle East and North Africa;
sexual health; women's health EXTENDED MIDDLE-EAST; CERVICAL-
CANCER; UNITED-STATES; LESBIANS; PREVALENCE; MINORITY; MEN;
DISPARITIES; KNOWLEDGE; BEHAVIOR Purpose: From studies conducted
in Western countries (United States, United Kingdom, and
Australia), we know that the sexual health of sexual minority
women (SMW) differs in key ways from that of heterosexual women
(HSW). To date, the sexual health of SMW living in the Middle East
and North Africa region has not been studied. The purpose of this
study was to compare the sexual health of SMW and HSW living in
Lebanon. Methods: SMW and HSW living in Lebanon (N=95) completed
an anonymous, self-administered survey. SMW's risk perceptions and
health promoting and sexual behaviors were compared to those of
HSW. We examined differences by sexual orientation by using t
tests and Fisher's exact tests. Results: The 45 SMW and 50 HSW had
similar demographic characteristics. Significantly more SMW had
heard of human papillomavirus, but only 22% of women from both
groups knew of its association with abnormal Papanicolaou tests.
Cervical cancer screening rates were similar in SMW and HSW,
although remarkably low (42%) compared with rates in Western
countries. Significantly more SMW (18%) reported difficulty with
access to care than HSW (0%). Forty-four percent of SMW reported
discomfort in disclosing their sexual orientation to their
healthcare provider and 61% reported that healthcare providers
lacked sensitivity toward lesbian, gay, bisexual, and transgender
needs. Unwanted sexual contact occurred more frequently in SMW
(53%) than HSW (23%). Conclusion: The sexual health of women is
affected by sociocultural factors. SMW living in Lebanon have
unique health needs that should be addressed within their
sociocultural context. [Gereige, Jessica D.] Massachusetts Gen

J Escrich, E; Moral, R; Solanas, M Escrich,
Eduard; Moral, Raquel; Solanas, Montserrat Olive
oil, an essential component of the Mediterranean diet, and breast
cancer PUBLIC HEALTH NUTRITION English

Article

Mediterranean diet;

Olive oil; Breast cancer HIGH CORN-OIL; INDUCED MAMMARY-
CARCINOMA; FATTY-ACID; LIPID INFLUENCE; OLEIC-ACID; RAT;
APOPTOSIS; TUMORS; RISK; EXPRESSION Objective: The
Mediterranean diet has been related to a lower risk of some
chronic diseases, including cancer. We aim to gain insight into
the effects of the main source of fat of this diet on breast
cancer, the most common type of malignancy in women. Design: Data
from sixteen experimental series analysing the effects of dietary
lipids on mammary carcinogenesis in an animal model, in the
context of the international literature on the Mediterranean diet,
olive oil and breast cancer risk. Setting: Experimental and human
data on the effects of olive oil and Mediterranean diet on breast
cancer. Subjects: An animal model of induced breast cancer and
other human and experimental studies in the literature. Results:
Diets rich in extra virgin olive oil (EVOO) exert a negative
modulatory effect on experimental breast cancer to a weak
promoting effect, much lower than that obtained with a high-corn
oil diet. EVOO confers to the mammary adenocarcinomas a clinical
behaviour and morphological features compatible with low tumour
aggressiveness. This differential effect, in relation to other
dietary lipids, may be related to a lower effect on body weight
and sexual maturation. In addition, EVOO induced different
molecular changes in tumours, such as in the composition of cell
membranes, activity of signalling proteins and gene expression.
All these modifications could induce lower proliferation, higher
apoptosis and lower DNA damage. These results, together with the
favourable effect of olive oil reported in the literature when it
is consumed in moderate quantities, suggest a beneficial influence
of EVOO on breast cancer risk. Conclusions: Consumption of EVOO in
moderate quantities and throughout the lifetime appears to be a
healthy choice and may favourably influence breast cancer risk.

and Their Impact on Cervical Cancer Prevention Practices among
Sub-Saharan African and Middle Eastern Refugees HEALTH EQUITY
English Article

cervical cancer screening; HPV vaccination; pap test;
refugee women IMMIGRANT; COMMUNITY Objective: The purpose of
the study was to understand cervical cancer screening and
prevention practices of refugee women in San Diego, California and
identify desired components of a cervical cancer screening

toolkit. Methods: We conducted a qualitative study utilizing semi-structured focus groups and identified common themes via grounded theory analysis. Results: There were 53 female refugee participants from Sub-Saharan Africa and the Middle East. Over half of all women surveyed expressed a fear of pelvic exams and loss of modesty as barriers to seeking gynecologic care, with nearly 34% avoiding routine pap tests. Of the 18 participants who were asked if they were aware of the Human Papilloma Virus (HPV) vaccination, only one had heard of the vaccine and none had received it for themselves or their children. Over 60% of participants were interested in educational materials surrounding HPV and pap tests. Conclusion: There is a significant lack of knowledge regarding cervical cancer screening and HPV vaccination among refugee women in San Diego, California. Refugee women in this study were interested in multi-modal educational materials as part of a cervical cancer screening toolkit. Identifies Rare Variants in APC Associated with High-Risk Colorectal Cancer in the Middle East CANCERS

English Article

colorectal cancer; exome-wide association study; rare variants; APC; high-risk CRC; Middle East; sequence kernel association test SIGNALING PATHWAYS; DIAGNOSIS; GROWTH; GENE

Background: Colorectal cancer (CRC) displays a complex pattern of inheritance. It is postulated that much of the missing heritability of CRC is enriched in high-impact rare alleles, which

might play a crucial role in the etiology and susceptibility of CRC. Methods: In this study, an exome-wide association analysis was performed in 146 patients with high-risk CRC in the Middle East and 1395 healthy controls. The aim was to identify rare germline variants in coding regions and their splicing sites associated with high-risk CRC in the Middle Eastern population. Results: Rare inactivating variants (RIVs) in APC had the strongest association with high-risk CRC (6/146 in cases vs. 1/1395 in controls, OR = 59.7, $p = 5.13 \times 10^{-12}$), whereas RIVs in RIMS1, an RAS superfamily member, were significantly associated with high-risk CRC (5/146 case vs. 2/1395 controls, OR = 24.7, $p = 2.03 \times 10^{-8}$). Rare damaging variants in 17 genes were associated with high-risk CRC at the exome-wide threshold ($p < 2.5 \times 10^{-6}$). Based on the sequence kernel association test, nonsynonymous variants in six genes (TNXB, TAP2, GPSM3, ADGRG4, TMEM229A, and ANKRD33B) had a significant association with high-risk CRC. RIVs in APC-the most common high-penetrance genetic factor-were associated with patients with high-risk CRC in the Middle East. Individuals who inherited APC RIVs had an approximate 60-fold increased risk of developing CRC and were likely to develop the disease earlier. Conclusions: We identified new potential CRC predisposition variants in other genes that could play a role in CRC inheritance. However, large collaborative studies are needed to confirm the association of these variants with high-risk CRC. These results provide information for counseling patients with high-risk CRC and their families in our population. The indirect costs of vaccine-preventable cancer mortality
in the Middle East and North Africa (MENA) JOURNAL OF MEDICAL
ECONOMICS English Article

Health economics; hepatitis B; prevention and control;
indirect costs; human papillomavirus; vaccine; I18; I1; I; I10
CLINICAL-TRIALS; GLOBAL BURDEN; INFECTIONS; IMPACT

Background Infections are responsible for similar to 13% of cancer cases worldwide, with human papillomavirus (HPV) and hepatitis B (HBV) among the infections associated with cancer for which vaccines are available. The aim of this study was to estimate the indirect cost of premature mortality related to cancers caused by HPV and HBV in Middle East and North Africa (MENA) countries. Methods The number of deaths and years of life lost (YLL) in 2019 from four HPV-related cancers: cervical cancer, oral cavity cancer, laryngeal cancer, and oropharynx cancer, as well as HBV-related liver cancer were sourced from the Institute for Health Metrics Evaluation (IHME) Global Burden of Disease database. HPV-attributable fractions were applied to deaths and YLL. The human capital approach was used to measure productivity loss, through value of YLL (VYLL), and estimated using gross domestic product per capita (World Bank; in USD). Seventeen countries in the MENA region were included. Four countries in the region were not included due to data availability. Results In 2019, there were 11,645 potentially vaccine-preventable cancer-related deaths across the MENA region. This resulted in an indirect cost of \$1,688,821,605, with 76.1% of this accrued in the Middle East (\$1,284,923,633). The number of deaths in the Middle East (5,986) were similar to Northern Africa (5,659) but YLL were higher in Northern Africa (179,425) compared to the Middle East (169,207). The highest indirect cost per death occurred in Qatar (\$1,378,991), compared to \$14,962 in Sudan. Oral cavity cancer had the highest VYLL per death (\$186,084). Conclusions There is a high burden of premature mortality and indirect costs of potentially vaccine-preventable cancer-related deaths in the MENA region. Improved vaccination program implementation, increased vaccine coverage of HPV and HBV vaccinations, and continued prioritization of public health measures, such as screening, could effectively reduce premature mortality and associated costs. POLE and POLD1 germline exonuclease domain
pathogenic variants, a rare event in colorectal cancer from the
Middle East MOLECULAR GENETICS & GENOMIC MEDICINE

English Article
colorectal cancers; Middle East; POLD1; POLE; variant
PAPILLARY THYROID-CANCER; MUTATIONS; POLYPOSIS; DIAGNOSIS;
ATTITUDES; ADENOMAS; SPECTRUM; GENE Background Colorectal
cancer (CRC) is a major contributor to morbidity and mortality
related to cancer. Only similar to 5% of all CRCs occur as a
result of pathogenic variants in well-defined CRC predisposing
genes. The frequency and effect of exonuclease domain pathogenic
variants of POLE and POLD1 genes in Middle Eastern CRCs is still
unknown. Methods Targeted capture sequencing and Sanger sequencing
technologies were employed to investigate the germline exonuclease
domain pathogenic variants of POLE and POLD1 in Middle Eastern CRCs.
Immunohistochemical analysis of POLE and POLD1 was performed to
look for associations between protein expression and clinico-
pathological characteristics. Results Five damaging or possibly
damaging variants (0.44%) were detected in 1,135 CRC cases, four
in POLE gene (0.35%, 4/1,135) and one (0.1%, 1/1,135) in POLD1 gene.
Furthermore, low POLE protein expression was identified in 38.9%
(417/1071) cases and a significant association with lymph node
involvement ($p = .0184$) and grade 3 tumors ($p = .0139$) was
observed. Whereas, low POLD1 expression was observed in 51.9%
(555/1069) of cases and was significantly associated with
adenocarcinoma histology ($p = .0164$), larger tumor size (T3 and T4
tumors; $p = .0012$), and stage III tumors ($p = .0341$). Conclusion
POLE and POLD1 exonuclease domain pathogenic variants frequency in
CRC cases was very low and these exonuclease domain pathogenic
variants might be rare causative events of CRC in the Middle
East. POLE and POLD1 can be included in multi-gene panels to screen
CRC patients. [Siraj, Abdul K.; Bu, Rong; Iqbal, Kaleem;

J Soliman, AS; Schairer, C Soliman, Amr
S.; Schairer, Catherine Considerations in setting
up and conducting epidemiologic studies of cancer in middle- and
low-income countries: the experience of a case-control study of
inflammatory breast cancer in North Africa in the past 10 years
CANCER MEDICINE English Article

Breast cancer; Egypt; epidemiology; field
methods; Morocco; North Africa; Tunisia This article
illustrates some issues we faced during our experience in
conducting an epidemiologic case-control study of inflammatory
breast cancer in North Africa. We expect that some of the
questions we had to ask in order to address these issues might be
helpful to others in setting up epidemiologic studies in
developing regions. We describe our experience from different
angles including the use of multiple sites to achieve adequate
sample size, standardizing diagnosis of disease, identifying
cancer cases at the time of diagnosis, control selection
procedures, logistics of study implementation, questionnaire
development and interviewing, biologic specimens, and procedures
for protection of human subjects. We have developed a brief
checklist to summarize important issues for conducting future
epidemiologic studies in these or similar low- or middle-income
countries. [Soliman, Amr S.] Univ Michigan, Sch Publ Hlth, Dept

Low attendance by non-native women to human papillomavirus vaccination and cervical cancer screening - A Danish nationwide register-based cohort study PREVENTIVE

MEDICINE REPORTS English Article

Human papilloma virus; Vaccination; Screening; Non-participation; Non-attendance; Denmark; Socio-economic status; NationalityETHNIC-MINORITY; IMMUNIZATION; EXPERIENCES; IMMIGRANTS; PREVENTION; COUNTRIES; BARRIERS; DENMARK; GIRLS

Background: Cervical cancer is preventable through human papillomavirus vaccination and cervical cancer screening. However, possibly due to systemic, individual (e.g. low socio-economic status) and socio-cultural barriers, it is likely that non-natives, especially non-westerns, are more prone to attend neither vaccination nor screening (combined non-attendance). This is disturbing as the non-native population in Denmark is predicted to rise to 21% by 2060. We aimed to investigate differences in combined non-attendance by nativity and region of origin, and to analyse the association between country of origin and combined non-attendance adjusted for socio-economic status. Setting: 1.6.2007-31.12.2016 Denmark. Methods: Logistic regression was performed to estimate crude and adjusted odds ratios with 95% confidence intervals for combined non-attendance. Results: 170,158 women were included. Overall combined non-attendance was 11.8% [11.7-12.0]; 10.0% [9.8-10.1] for native women and 27.1% [26.4-27.7] for non-native women, with highest degrees among Middle-Eastern and North-Africans (30.1% [29.2-30.9]). Even when adjusted for socio-economics, women from Middle-East and North-Africa had substantially higher odds of combined non-attendance than natives (adj. OR = 7.5 [6.3-8.9] for Somali women). Conclusion: Denmark has a relatively low degree of combined non-attendance. However, cervical cancer preventive programmes seem to be better tailored to the needs of native women and do not appear to cater sufficiently to the needs of the fast-growing non-native populations, particularly not to the needs of Middle-Eastern and North African women. In order to secure more just cervical cancer prevention, future studies are recommended to develop tailored intervention sensitive to the need of non-native women. [Badre-Esfahani, S.; Larsen, M. Eastern Mediterranean Region During the Years 2000 and 2017:
Retrospective Data Analysis of the Global Burden of Disease Study
JMIR PUBLIC HEALTH AND SURVEILLANCE English
Article cervical cancer;
Eastern Mediterranean Region; burden of disease; cancer; burden;
inequality; mortality; preventable disease EXTENDED MIDDLE-EAST;
ATTITUDES Background: Cervical cancer is a growing health
concern, especially in resource-limited settings. Objective: The
objective of this study was to assess the burden of cervical
cancer mortality and disability-adjusted life years (DALYs) in the
Eastern Mediterranean Region (EMR) and globally between the years
2000 and 2017 by using a pooled data analysis approach. Methods:
We used an ecological approach at the country level. This included
extracting data from publicly available databases and linking them
together in the following 3 steps: (1) extraction of data from the
Global Burden of Disease (GBD) study in the years 2000 and 2017,
(2) categorization of EMR countries according to the World Bank
gross domestic product per capita, and (3) linking age-specific
population data from the Population Statistics Division of the
United Nations (20-29 years, 30-49 years, and >50 years) and GBD's
data with gross national income per capita and globally extracted

data, including cervical cancer mortality and DALY numbers and rates per country. The cervical cancer mortality rate was provided by the GBD study using the following formula: number of cervical cancer deaths x 100,000/female population in the respective age group. Results: The absolute number of deaths due to cervical cancer increased from the year 2000 (n=6326) to the year 2017 (n=8537) in the EMR; however, the mortality rate due to this disease decreased from the year 2000 (2.7 per 100,000) to the year 2017 (2.5 per 100,000). According to age-specific data, the age group ≥ 50 years showed the highest mortality rate in both EMR countries and globally, and the age group of 20-29 years showed the lowest mortality rate both globally and in the EMR countries. Further, the rates of cervical cancer DALYs in the EMR were lower compared to the global rates (2.7 vs 6.8 in 2000 and 2.5 vs 6.8 in 2017 for mortality rate per 100,000; 95.8 vs 222.2 in 2000 and 86.3 vs 211.8 in 2017 for DALY rate per 100,000; respectively). However, the relative difference in the number of DALYs due to cervical cancer between the year 2000 and year 2017 in the EMR was higher than that reported globally (34.9 vs 24.0 for the number of deaths and 23.5 vs 18.1 for the number of DALYs, respectively). Conclusions: We found an increase in the burden of cervical cancer in the EMR as per the data on the absolute number of deaths and DALYs. Further, we found that the health care system has an increased number of cases to deal with, despite the decrease in the absolute number of deaths and DALYs. Cervical cancer is preventable if human papilloma vaccination is taken and early screening is performed. Therefore, we recommend identifying effective vaccination programs and interventions to reduce the burden of this disease. Clinico-pathologic and mammographic characteristics of inflammatory and non-inflammatory breast cancer at six centers in North Africa

BREAST CANCER RESEARCH AND TREATMENT

English Article

Inflammatory breast cancer; Diagnostic criteria; Egypt; Tunisia; Morocco CARCINOMA; DIAGNOSIS; CONSENSUS; TUNISIA; PROGRAM

PurposeWe describe the clinico-pathologic and mammographic characteristics of inflammatory breast cancer (IBC) and non-IBC cases enrolled in a case-control study. Because IBC is a clinico-pathologic entity with rapid appearance of erythema and other signs, its diagnosis is based on clinical observation and thus, by necessity, subjective. Therefore, we evaluate our cases by photographic review by outside expert clinicians and by degree of adherence to the two most recent definitions of IBC: the international expert panel consensus statement and American Joint Committee on Cancer (AJCC) 8th edition (we used the slightly less restrictive 7th edition definition for our study). **Methods**We enrolled 267 IBC and 274 age- and geographically matched non-IBC cases at 6 sites in Egypt, Tunisia, and Morocco in a case-control study of IBC conducted between 2009 and 2015. We collected clinico-pathologic and mammographic data and standardized medical photographs of the breast. **Results**We identified many differences between IBC and non-IBC cases: 54.5% versus 68.8% were estrogen receptor-positive, 39.9% versus 14.8% human epidermal growth factor receptor 2-positive, 91% versus 4% exhibited erythema, 63% versus 97% had a mass, and 57% versus 10% had mammographic evidence of skin thickening. Seventy-six percent of IBC cases adhered to the expert panel consensus statement and 36% to the AJCC definition; 86 percent were confirmed as IBC by either photographic review or adherence to the consensus statement. **Conclusions**We successfully identified distinct groups of IBC and non-IBC cases. The reliability of IBC diagnosis would benefit from expert review of standardized medical photographs and associated clinical information. Dietary index scores and invasive breast cancer risk among women with a family history of breast cancer AMERICAN JOURNAL OF CLINICAL NUTRITION English Article

breast cancer; dietary index; cohort studies; DASH diet; Mediterranean diet; Alternative Healthy Eating Index DASH-STYLE DIET; MEDITERRANEAN DIET; POOLED ANALYSIS; REGRESSION-MODELS; LIFE-STYLE; ADHERENCE; CONSUMPTION; DISEASE; QUALITY; METAANALYSIS Background: Many epidemiologic studies have analyzed the relations of individual foods and nutrients and breast cancer risk with inconsistent results. Few studies have examined recommendation-based dietary indices and breast cancer risk. Objective: The aim of this study was to determine associations between recommendation-based dietary index scores and incident invasive breast cancer. Methods: The Sister Study is a prospective cohort of 50,884 US women (baseline: 2003-2009) who had a sister with breast cancer but no prior breast cancer themselves. We created scores for the Dietary Approaches to Stop Hypertension (DASH) diet, Alternative Mediterranean Diet (AMED), and Alternative Healthy Eating Index-2010 (AHEI-2010) from

dietary intakes estimated by a baseline-validated Block food-frequency questionnaire (FFQ). We used Cox regression to estimate multivariable-adjusted HRs and 95% CIs for total invasive breast cancer risk and by estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor receptor-2 (HER2) status. Results: We documented 1,700 invasive breast cancer cases through 2015 (mean follow-up, 7.6 y). Individuals in the highest quartile of DASH scores had a lower risk of invasive breast cancer compared with those in the lowest quartile (HR: 0.78; 95% CI: 0.67, 0.90; P-trend = 0.001), with stronger associations for ER (HR: 0.61; 95% CI: 0.40, 0.94; P-trend = 0.006) as well as ER-/PR- and ER-/PR-/HER2-subtypes. AHEI-2010 (HR for highest compared with lowest quartile: 0.90; 95% CI: 0.78, 1.03; P-trend = 0.15) and AMED (HR for highest compared with lowest quartile: 0.90; 95% CI: 0.77, 1.06; P-trend = 0.07) were weakly and nonsignificantly associated with breast cancer risk, but after excluding alcohol, AHEI-2010 was inversely associated with risk of ER-/PR- (HR: 0.64; 95% CI: 0.42, 0.98; P-trend = 0.04) and ER-/PR-/HER2-subtypes. We did not observe any significant interactions by menopausal status or other participant characteristics. Conclusions: DASH scores were inversely associated with breast cancer risk; DASH and AHEI-2010 scores excluding alcohol were particularly inversely associated with risk of ER-/PR- and ER-/PR-/HER2-breast cancers. This trial was registered at clinicaltrials.gov as NCT00047970. Adherence to the Western, Prudent and Mediterranean dietary patterns and breast cancer risk: MCC-Spain study MATURITAS

English Article

Mediterranean diet; Western diet; Breast neoplasms; Prevention and control; Population attributable fractionFOOD; AMERICAN; SUBTYPES Objective: To externally validate the previously identified effect on breast cancer risk of the Western, Prudent and Mediterranean dietary patterns. Study design: MCC-Spain is a multicase-control study that collected epidemiological information on 1181 incident cases of female breast cancer and 1682 healthy controls from 10 Spanish provinces. Three dietary patterns derived in another Spanish case-control study were analysed in the MCC-Spain study. These patterns were termed Western (high intakes of fatty and sugary products and red and processed meat), Prudent (high intakes of low-fat dairy products, vegetables, fruits, whole grains and juices) and Mediterranean (high intake of fish, vegetables, legumes, boiled potatoes, fruits, olives, and vegetable oil, and a low intake of juices). Their association with breast cancer was assessed using logistic regression models with random province-specific intercepts considering an interaction with menopausal status. Risk according to tumour subtypes based on oestrogen (ER), progesterone (PR) and human epidermal growth factor 2 (HER2) receptors (ER +/PR + HER2; HER2+; ER- /PR- & HER2-) -was evaluated with multinomial regression models. Main outcome measures: Breast cancer and histological subtype. Results: Our results confirm most of the associations found in the previous case-control study. A high adherence to the Western dietary pattern seems to increase breast cancer risk in both premenopausal women (OR4th vs 1st quartile (95% CI):1.68 (1.02;2.79); ORISD-increase (95% CI):1.19 (1.02;1.40)) and postmenopausal women (OR4th vs 1st quartile(95% CI):1.48(1.07;2.05); ORISD-increase(95% CO: 1.14 (1.01;1.29)). While high adherence to the Prudent pattern did not show any effect on breast cancer, the Mediterranean dietary pattern seemed to be protective, but only among postmenopausal women (OR4th vs 1st quartile (95% CI): 0.72 (95% CI 0.53;0.98); p-int = 0.075). There were no significant differences by tumour subtype. Conclusion: Dietary recommendations based on a departure from the Western dietary pattern in favour of the Mediterranean diet could reduce breast cancer risk in the general population.

Adherence to the Vegetable-Fruit-Soy Dietary Pattern, a
Reference From Mediterranean Diet, Protects Against Postmenopausal
Breast Cancer Among Chinese Women FRONTIERS IN NUTRITION

English Article

breast

cancer; Mediterranean diet; cancer prevention; molecular subtype;
vegetable-fruit-soy diet POOLED ANALYSIS; RISK; CAROTENOIDS;
MORTALITY; CONSUMPTION; NUTRITION; SURVIVAL; QUALITY; HABITS;
COHORT BackgroundThe diet-center hypothesis has gained much

support from the apparent protective effect of the Mediterranean
diet on breast cancer. However, the evidence of the association
between Mediterranean diet adherence and breast cancer molecular
subtypes remains small, especially in non-Mediterranean
populations. MethodsThe subjects from the Chinese Wuxi Exposure
and Breast Cancer Study, a population-based case-control study,
included 818 patients and 935 healthy controls. A validated food
frequency questionnaire used for diet assessment and a modified
version of the alternate Mediterranean Diet Score, which is called
the alternate Chinese Diet Score, was developed to assess
adherence to a migrated Chinese version of the Mediterranean diet,
which we called the vegetable-fruit-soy dietary pattern. Soy
foods, rapeseed oil, and coarse cereals replaced legumes, olive
oil, and whole grains reflecting the cuisine of the region. We
examined the association between the vegetable-fruit-soy diet
adherence and breast cancer risk, stratified by menopause status
(pre- or postmenopausal) and receptor status [estrogen-receptor
(ER), progesterone-receptor (PR) status, and human epidermal
growth factor 2 (HER2)] oncogene expression, followed by five
specific combinations (ER+, ER-, ER+/PR+, ER-/PR-, and ER-/PR-
/HER2-). ResultsThe results suggest that the vegetable-fruit-soy
dietary pattern was inversely associated with postmenopausal
breast cancer risk [4th vs. 1st quartile, odds ratio (OR) = 0.57,
95%CI = 0.41, 0.80; P trend < 0.001] and that the inverse
association was somewhat stronger to detect among ER- subtypes (OR
= 0.63; 95%CI = 0.37, 0.94; P trend = 0.003) and ER-/PR-subtypes
(OR = 0.64; 95%CI = 0.41, 0.93; P trend = 0.012). We did not
observe any significant association between the vegetable-fruit-
soy diet characteristics and ER+ subtype, as well as between PR+
and ER+/PR+ subtypes. ConclusionThe favorable influence from the
Mediterranean diet may also apply to Chinese women. The vegetable-
fruit-soy dietary pattern may reduce the risk of postmenopausal
breast cancer, particularly among ER- subtype, and ER-/PR-subtype.

survival after breast cancer diagnosis in women from nine European countries: results from the EPIC cohort study BMC MEDICINE English Article

Mediterranean diet; Breast cancer; Cancer survivors; Dietary patterns; Prospective studies ADHERENCE; DEATH; RISK

BackgroundThe Mediterranean diet has been associated with lower risk of breast cancer (BC) but evidence from prospective studies on the role of Mediterranean diet on BC survival remains sparse and conflicting. We aimed to investigate whether adherence to Mediterranean diet prior to diagnosis is associated with overall and BC-specific mortality.MethodsA total of 13,270 incident breast cancer cases were identified from an initial sample of 318,686 women in 9 countries from the European Prospective Investigation into Cancer and Nutrition (EPIC) study. Adherence to Mediterranean diet was estimated through the adapted relative Mediterranean diet (arMED), a 16-point score that includes 8 key components of the Mediterranean diet and excludes alcohol. The degree of adherence to arMED was classified as low (score 0-5), medium (score 6-8), and high (score 9-16). Multivariable Cox proportional hazards models were used to analyze the association between the arMED score and overall mortality, and

Fine-Gray competing risks models were applied for BC-specific mortality. Results After a mean follow-up of 8.6 years from diagnosis, 2340 women died, including 1475 from breast cancer. Among all BC survivors, low compared to medium adherence to arMED score was associated with a 13% higher risk of all-cause mortality (HR 1.13, 95%CI 1.01-1.26). High compared to medium adherence to arMED showed a non-statistically significant association (HR 0.94; 95% CI 0.84-1.05). With no statistically significant departures from linearity, on a continuous scale, a 3-unit increase in the arMED score was associated with an 8% reduced risk of overall mortality (HR3-unit 0.92, 95% CI: 0.87-0.97). This result sustained when restricted to postmenopausal women and was stronger among metastatic BC cases (HR3-unit 0.81, 95% CI: 0.72-0.91).

Conclusions Consuming a Mediterranean diet before BC diagnosis may improve long-term prognosis, particularly after menopause and in cases of metastatic breast cancer. Well-designed dietary interventions are needed to confirm these findings and define specific dietary recommendations.

J Bennacef, AC; Khodja, AA; Abou-Bekr, FA; Ndao, T; Holl, R; Bencina, G Bennacef, Ali-Chakib; Khodja, Aomar Ammar; Abou-Bekr, Fadl Allah; Ndao, Tidiane; Holl, Ryan; Bencina, Goran Costs and Resource Use Among Patients with Cervical Cancer, Cervical Intraepithelial Neoplasia, and Genital Warts in Algeria JOURNAL OF HEALTH ECONOMICS AND OUTCOMES RESEARCH

papillomavirus infections; sexually transmitted viral diseases; genital warts; North Africa epidemiology; Algeria epidemiology; burden of illness; cost of illness EXTENDED MIDDLE-EAST; HUMAN-PAPILLOMAVIRUS INFECTIONS; BURDEN; PREVENTION; MANAGEMENT; DISEASES; EUROPE; WOMEN; HPV Background: Cervical cancer rates in North Africa have risen in the last 10 years, suggesting that this region might benefit from cervical cancer screening and HPV vaccination programs. To assess the potential benefits of cervical cancer screening and HPV vaccination in North African countries, country-specific data on the prevalence and burden of HPV-related conditions are needed. Objectives: To describe the patterns and estimate the costs of management of cervical cancer, cervical intraepithelial neoplasia (CIN), and genital warts in Algeria. Methods: This was a descriptive analysis of questionnaire data obtained from a panel of 15 oncologists, gynecologists, and dermatologists (n=5 each). Data on diagnostic and treatment patterns, recurrence, and healthcare resource use (HCRU) were obtained. The costs (in Algerian dinars) associated with diagnosis, treatment, and recurrence were estimated. Results: Diagnosis of CIN was obtained by cytology tests or lesion biopsies; for cervical cancer, lesion biopsies, MRI, and CT scans were the most common diagnostic tests. For CIN, 70% of gynecologists and oncologists regularly or always used conization as a treatment. Treatments used regularly or always for cervical cancer included chemotherapy (80%), hysterectomy (70%), and radiation (70%). Annual HCRU per institution included 20 outpatient visits and 15 hospitalizations for CIN, and 50 outpatient visits and 11 hospitalizations for cervical cancer. For genital warts, diagnostic tests performed regularly or always included assays for hepatitis B, hepatitis C, HIV, and syphilis; cervical cytology; and colposcopy. Cryotherapy was the universal first-line treatment. Median per-patient costs associated with diagnosis, treatment, and recurrence were 6750, 19 750, and 77 750, respectively, for CIN; 53 750, 650 000, and 431 250, respectively, for cervical cancer; and 16 075, 15 500, and 9250, respectively, for genital warts. Discussion: These results give an estimate of the HCRU and cost of cervical cancer, CIN, and genital warts and highlight the need to assess more precisely the epidemiology of these diseases in Algeria. Conclusions: This study investigated the management of patients with cervical cancer, CIN, or genital warts in Algeria and provided the first estimates of diagnosis and treatment patterns, HCRU, and costs associated with these conditions. These resource use and cost estimates highlight the need to develop prevention strategies for HPV-related pathologies. PREvencion Con Dleta MEDiterDairy Product Consumption and Risk of Colorectal Cancer in an Older Mediterranean Population at High Cardiovascular Risk INTERNATIONAL JOURNAL OF CANCER
English Article

colorectal cancer; mediterranean diet; dairy products; milk; PREDIMED study CONJUGATED LINOLEIC-ACID; VITAMIN-D; COHORT; DIET; CALCIUM; FOOD; METAANALYSIS; MECHANISMS; DISEASE; MILK

Prospective studies have reported an inverse association between the consumption of total dairy products and milk and the risk of colorectal cancer (CRC). Nonetheless, there is little and inconsistent evidence regarding subtypes of dairy product and CRC risk. We assessed the associations between the consumption of total dairy products, their different subtypes and CRC risk in older Mediterranean individuals at high cardiovascular risk. We analyzed data from 7,216 men and women (55-80 years) without CRC at baseline from the PREvencion con DIeta MEDiterranea study. Individuals were recruited between 2003 and 2009 and followed up until December 2012. At baseline and yearly thereafter, consumption of total and specific dairy products was assessed using a validated 137-item food-frequency questionnaire. Cox proportional hazards ratios (HRs) of CRC incidence were estimated for tertiles of mean consumption of dairy products during the follow-up. During a median [interquartile range] follow-up of 6.0 [4.4-7.3] years, we documented 101 incident CRC cases. In the multivariable-adjusted models, HRs and 95% confidence intervals (CIs) of CRC for the comparison of extreme tertiles of total dairy product and low-fat milk consumption were 0.55 (95% CI: 0.31-0.99; p-trend = 0.037) and 0.54 (95% CI: 0.32-0.92; p-trend = 0.022), respectively. No significant associations with other dairy products (whole-fat and low-fat dairy products; total, low-fat and whole-fat yogurt; cheese; total, low-fat and whole-fat milk; concentrated full-fat dairy products, sugar-enriched dairy products and fermented dairy products) were found. A high consumption of total dairy products and low-fat milk was significantly associated with a reduced CRC risk. spectrum of BRCA1 and BRCA2 pathogenic sequence variants in Middle
Eastern, North African, and South European countries HUMAN
MUTATION English Article

BRCA1 BRCA2 mutational spectrum; first pass
genotyping; inherited breast cancer; Middle East; North Africa;
underserved populations BREAST-CANCER PATIENTS; FOUNDER
MUTATIONS; HAPLOTYPE ANALYSIS; ASHKENAZI JEWISH; OVARIAN-CANCER;
RECURRENT; POPULATION; RISK; IDENTIFICATION; PREVALENCE BRCA1
BRCA2 mutational spectrum in the Middle East, North Africa, and
Southern Europe is not well characterized. The unique history and
cultural practices characterizing these regions, often involving
consanguinity and inbreeding, plausibly led to the accumulation of
population-specific founder pathogenic sequence variants (PSVs).
To determine recurring BRCA PSVs in these locales, a search in
PUBMED, EMBASE, BIC, and CIMBA was carried out combined with
outreach to researchers from the relevant countries for
unpublished data. We identified 232 PSVs in BRCA1 and 239 in BRCA2
in 25 of 33 countries surveyed. Common PSVs that were detected in
four or more countries were c.5266dup (p.Gln1756Profs), c.181T>G
(p.Cys61Gly), c.68_69del (p.Glu23Valfs), c.5030_5033del
(p.Thr1677Ilefs), c.4327C>T (p.Arg1443Ter), c.5251C>T
(p.Arg1751Ter), c.1016dup (p.Val340Glyfs), c.3700_3704del
(p.Val1234Glnfs), c.4065_4068del (p.Asn1355Lysfs), c.1504_1508del
(p.Leu502Alafs), c.843_846del (p.Ser282Tyrfs), c.798_799del
(p.Ser267Lysfs), and c.3607C>T (p.Arg1203Ter) in BRCA1 and
c.2808_2811del (p.Ala938Profs), c.5722_5723del (p.Leu1908Argfs),
c.9097dup (p.Thr3033Asnfs), c.1310_1313del (p.p.Lys437Ilefs), and
c.5946del (p.Ser1982Argfs) for BRCA2. Notably, some mutations
(e.g., p.Asn257Lysfs (c.771_775del)) were observed in unrelated
populations. Thus, seemingly genotyping recurring BRCA PSVs in
specific populations may provide first pass BRCA genotyping
platform. [Laitman, Yael; Friedman, Eitan] Sheba Med Ctr, Inst

Adherence to the mediterranean diet and risk of breast cancer in the European prospective investigation into cancer and nutrition cohort study

INTERNATIONAL JOURNAL OF CANCER English
Article breast cancer;
Europe; Mediterranean diet; prospective studies FATTY-ACID;
PATTERNS; ESTROGEN; CALIBRATION; RATIONALE; VALIDITY; DISEASE;

GROWTH; CELLS Epidemiological evidence suggests that the Mediterranean diet (MD) could reduce the risk of breast cancer (BC). As evidence from the prospective studies remains scarce and conflicting, we investigated the association between adherence to the MD and risk of BC among 335,062 women recruited from 1992 to 2000, in ten European countries, and followed for 11 years on average. Adherence to the MD was estimated through an adapted relative Mediterranean diet (arMED) score excluding alcohol. Cox proportional hazards regression models were used while adjusting for BC risk factors. A total of 9,009 postmenopausal and 1,216 premenopausal first primary incident invasive BC were identified (5,862 estrogen or progesterone receptor positive [ER+/PR+] and 1,018 estrogen and progesterone receptor negative [ER/PR]). The arMED was inversely associated with the risk of BC overall and in postmenopausal women (high vs. low arMED score; hazard ratio [HR] = 0.94 [95% confidence interval [CI]: 0.88, 1.00] ptrend = 0.048, and HR = 0.93 [95% CI: 0.87, 0.99] ptrend = 0.037, respectively). The association was more pronounced in ER/PR tumors (HR = 0.80 [95% CI: 0.65, 0.99] ptrend = 0.043). The arMED score was not associated with BC in premenopausal women. Our findings show that adherence to a MD excluding alcohol was related to a modest reduced risk of BC in postmenopausal women, and this association was stronger in receptor-negative tumors. The results support the potential scope for BC prevention through dietary modification.

 Cancer; Mortality; Incidence; Risk factors; Eastern Mediterranean regionHEPATITIS-C VIRUS; GLOBAL BURDEN; BREAST-CANCER; HEALTH OUTCOMES; CERVICAL-CANCER; AIR-POLLUTION; DISEASE; EGYPT; SCHISTOSOMIASIS; SMOKING Background: Many countries in the Eastern Mediterranean region (EMR) are undergoing marked demographic and socioeconomic transitions that are increasing the cancer burden in region. We sought to examine the national cancer incidence and mortality profiles as a support to regional cancer control planning in the EMR. Methods: GLOBOCAN 2012 data were used to estimate cancer incidence and mortality by country, cancer type, sex and age in 22 EMR countries. We calculated age- standardized incidence and mortality rates (per 100,000) using direct method of standardization. Results: The cancer incidence and mortality rates vary considerably between countries in the EMR. Incidence rates were highest in Lebanon (204 and 193 per 100,000 in males and females, respectively). Mortality rates were highest in Lebanon (119) and Egypt (121) among males and in Somalia (117) among females. The profile of common cancers differs substantially by sex. For females, breast cancer is the most common cancer in all 22 countries, followed by cervical cancer, which ranks high only in the lower-income countries in the region. For males, lung, prostate, and colorectal cancer in combination represent almost 30% of the cancer burden in countries that have attained very high levels of human development. Conclusions: The most common cancers are largely amenable to preventive strategies by primary and/or secondary prevention, hence a need for effective interventions tackling lifestyle risk factors and infections. The high mortality observed from breast and cervical cancer highlights the need to break the stigmas and improve awareness surrounding these cancers. (C) 2017 Published by Elsevier Ltd. J Simkhada, P; van Teijlingen, E; Gurung, M; Wasti, SP
Simkhada, Padam; van Teijlingen, Edwin; Gurung,
Manju; Wasti, Sharada P. A survey of health
problems of Nepalese female migrants workers in the Middle-East
and Malaysia BMC INTERNATIONAL HEALTH AND HUMAN RIGHTS
English Article

Health problems; Migration; Exploitation; South Asia; Nepal;
Women; Gulf countries; Malaysia DOMESTIC WORKERS; HONG-KONG
Background: Nepal is a key supplier of labour for countries
in the Middle East, India and Malaysia. As many more men than
women leave Nepal to work abroad, female migrant workers are a
minority and very much under-researched. The aim of the study was
to explore the health problems of female Nepalese migrants working
in the Middle-East and Malaysia. Methods: The study was conducted
among 1010 women who were registered as migrant returnees at an
organisation called Pourakhi Nepal. Secondary data were extracted
from the records of the organisation covering the five-year period
of July 2009 to July 2014. Results: The 1010 participants were
aged 14 to 51 with a median age of 31 (IQR: 38-25) years. A
quarter of respondents (24%) reported having experienced health
problems while in the country of employment. Fever, severe illness
and accidents were the most common health problems reported.
Working for unlimited periods of time and not being able to change
one's place of work were independently associated with a greater
likelihood of health problems. Logistic regression shows that
migrant women who are illiterate [OR = 1.56, 95% CI: 1.02 to 2.38,
p = 0.042], who had changed their workplace [OR = 1.63, 95% CI:
1.14 to 2.32, p = 0.007], who worked unlimited periods of time [OR
= 1.64, 95% CI: 1.44 to 1.93, p = 0.020], had been severely
maltreated or tortured in the workplace [OR = 1.84, 95% CI: 1.15
to 2.92, p = 0.010], were not being paid on time [OR = 2.38, 95%
CI: 1.60 to 3.55, p = 0.038] and migrant women who had family
problems at home [OR = 3.48, CI 95%: 1.22 to 9.98, p = 0.020] were
significantly associated with health problems in their host
country in the Middle East. Conclusion: Female migrant workers
face various work-related health risks, which are often related to
exploitation. The Government of Nepal should initiate awareness
campaigns about health risks and rights in relation to health care
services in the host countries. Recruiting agencies/employers

should provide information on health risks and training for preventive measures. Raising awareness among female migrant workers can make a change in their working lives. breast cancer predisposition; breast cancer risk factors; FANCM truncating variants; mutation spectrum; PTVs RISK; MUTATIONS; BRCA1; C.5791C-GREATER-THAN-T; ANEMIA; GENE

Germline protein truncating variants (PTVs) in the FANCM gene have been associated with a 2-4-fold increased breast cancer risk in case-control studies conducted in different European populations. However, the distribution and the frequency of FANCM PTVs in Europe have never been investigated. In the present study, we collected the data of 114 European female breast cancer cases with FANCM PTVs ascertained in 20 centers from 13 European countries. We identified 27 different FANCM PTVs. The p.Gln1701* PTV is the most common PTV in Northern Europe with a maximum frequency in Finland and a lower relative frequency in Southern Europe. On the contrary, p.Arg1931* seems to be the most common PTV in Southern Europe. We also showed that p.Arg658*, the third most common PTV, is more frequent in Central Europe, and p.Gln498Thrfs*7 is probably a founder variant from Lithuania. Of the 23 rare or unique FANCM PTVs, 15 have not been previously reported. We provide here the initial spectrum of FANCM PTVs in European breast cancer cases.  Inequalities in Cervical Cancer Incidence and Mortality MIDDLE
 EAST JOURNAL OF CANCER English Article
 Human Development Index; Cervical cancer;
 Correlation; GLOBOCAN Cancer Project HUMAN-PAPILLOMAVIRUS;
 SURVIVAL; COUNTRIES; BURDEN; PREVALENCE; PATTERNS; OBESITY;
 REGIONS; TRENDS; BREAST Background: Cervical cancer is the
 third most common cancer in women after breast and colorectal
 cancers, and one of the leading causes of cancer death among women
 worldwide. The aim of this study is to determine the associations
 of cervical cancer incidence and mortality rates with the Human
 Development Index. Methods: Information of the incidence and
 mortality rates for cervical cancer were obtained from the
 GLOBOCAN Cancer Project for 2012 and data for the Human
 Development Index for 2013 from the World Bank database. We used
 linear regression models to assess the Human Development Index
 effect on cervical cancer occurrence rates. Inequality in the age-
 standardized incidence and mortality rates of cervical cancer
 according to the Human Development Index were assessed by the
 concentration index. Results: The results showed substantially
 higher cervical cancer incidence and mortality rates in regions
 with low and medium Human Development Index compared to regions
 that had substantially elevated Human Development Index. The death
 and incidence from cervical cancer were more concentrated in low
 Human Development Index countries. There was a significant
 negative association between the cervical cancer incidence and
 mortality rates with all the components of the Human Development
 Index, including life expectancy ($B=-0.98$, $P<0.001$), mean years of
 schooling ($B=-1.86$, $P<0.001$), gross national income ($B=-0.38$,
 $P<0.001$), urbanization level ($B=-0.29$, $P<0.001$), and age
 standardized obesity ($B=-0.45$, $P<0.001$). Conclusion: Cervical
 cancer is a significant public health problem in countries with
 low Human Development Index and requires the implementation of
 prevention programs and screening for early detection and
 treatment. [Mansori, Kamyar] Gonabad Univ Med Sci, Social Dev &

 Mohamed Financial and food security challenges of
 Egyptian women undergoing breast cancer treatment SUPPORTIVE CARE
 IN CANCER English Article
 Breast cancer; Egypt; Financial toxicity; Food
 insecurity; Patient navigation PATIENT NAVIGATION; CARE;
 DIAGNOSIS; COUNTRIES; BARRIERS; IMPACT Background Breast cancer
 treatment is an established cause of financial toxicity, and
 associated costs may contribute to higher mortality and morbidity
 rates. In Egypt, breast cancer incidence and mortality rates are
 among the highest in the Middle East. Late-stage diagnosis is
 common, and disease occurs at an earlier age than in Europe and
 North America. Out-of-pocket payments are the primary means of
 financing healthcare in Egypt, and socioeconomic factors have been
 shown to significantly impact access to cancer screening and
 treatment. Methods An observational cross-sectional study was
 conducted among breast cancer patients at Ain Shams University
 Hospitals in Cairo from 2013 to 2015. Results One hundred women
 with breast cancer participated. There was a high need for
 financial assistance (66.0%) and patients with financial needs had
 great difficulty affording medications (80.0%). A number of
 patients had lost their jobs following diagnosis, with 32.7%
 employed prior to diagnosis and 15.3% afterwards. Nearly one-half
 of participants were classified as food insecure, and nearly one-
 third reported difficulty affording transportation costs.
 Conclusions This is the first study to describe socioeconomic
 needs and financial impact among a cohort of Egyptian women
 undergoing breast cancer treatment. The findings highlight the
 financial impact of breast cancer treatment on a cohort of
 Egyptian breast cancer patients and the need for a
 multidisciplinary approach to help them access and mitigate the
 costs of treatment. Recommendations include implementing patient
 financial navigation services and producing printed materials to
 inform patients of resources to help mitigate the treatment's
 financial impact. [Gany, Francesca; Ayash, Claudia; Raad,

Heather Healthy dietary patterns and risk of breast cancer by molecular subtype BREAST CANCER RESEARCH AND TREATMENT English Article Breast cancer; Diet; Patterns; Molecular subtypes GENE-EXPRESSION PATTERNS; MEDITERRANEAN DIET; POOLED ANALYSIS; ESTROGEN-RECEPTOR; VEGETABLE INTAKE; EATING INDEX; QUALITY; ADHERENCE; COHORT; REPRODUCIBILITY We examined associations between dietary quality indices and breast cancer risk by molecular subtype among 100,643 women in the prospective Nurses' Health Study (NHS) cohort, followed from 1984 to 2006. Dietary quality scores for the Alternative Healthy Eating Index (AHEI), alternate Mediterranean diet (aMED), and Dietary Approaches to Stop Hypertension (DASH) dietary patterns were calculated from semi-quantitative food frequency questionnaires collected every 2-4 years. Breast cancer molecular subtypes were defined according to estrogen receptor (ER), progesterone receptor, human epidermal growth factor 2 (HER2), cytokeratin 5/6 (CK5/6), and epidermal growth factor receptor status from immunostained tumor microarrays in combination with histologic grade. Cox proportional hazards models, adjusted for age and breast cancer risk factors, were used to estimate hazard ratios (HRs) and 95 % confidence intervals (CIs). Competing risk analyses were used to assess heterogeneity by subtype. We did not observe any significant associations between the AHEI or aMED dietary patterns and risk of breast cancer by molecular subtype. However, a significantly reduced risk of HER2-type breast cancer was observed among women in 5th versus 1st quintile of the DASH dietary pattern [n = 134 cases, Q5 vs. Q1 HR (95 % CI) = 0.44 (0.25-0.77)], and the inverse trend across quintiles was significant (p trend = 0.02). We did not observe any heterogeneity in associations between AHEI (p (het) = 0.25), aMED (p (het) = 0.71), and DASH (p (het) = 0.12) dietary patterns and breast cancer by subtype. Adherence to the AHEI, aMED, and DASH dietary patterns was not strongly associated with breast cancer molecular subtypes. Breast cancer; Exome sequencing; Family specific predisposition; Non BRCA Tunisian families SUSCEPTIBILITY GENE; CYSTIC-FIBROSIS; RARE MUTATIONS; RISK; IDENTIFICATION; DNA; POLYMORPHISMS; ASSOCIATION; POPULATION; REVEALS Background: A family history of breast cancer has long been thought to indicate the presence of inherited genetic events that predispose to this disease. In North Africa, many specific epidemio-genetic characteristics have been observed in breast cancer families when

compared to Western populations. Despite these specificities, the majority of breast cancer genetics studies performed in North Africa remain restricted to the investigation of the BRCA1 and BRCA2 genes. Thus, comprehensive data at a whole exome or whole genome level from local patients are lacking. Methods: A whole exome sequencing (WES) of seven breast cancer Tunisian families have been performed using a family-based approach. We focused our analysis on BC-TN-F001 family that included two affected members that have been sequenced using WES. Relevant variants identified in BC-TN-F001 have been confirmed using Sanger sequencing. Then, we conducted an integrative analysis by combining our results with those from other WES studies in order to figure out the genetic transmission model of the newly identified genes. Biological network construction and protein-protein interactions analyses have been performed to decipher the molecular mechanisms likely accounting for the role of these genes in breast cancer risk. Results: Sequencing, filtering strategies, and validation analysis have been achieved. For BC-TN-F001, no deleterious mutations have been identified on known breast cancer genes. However, 373 heterozygous, exonic and rare variants have been identified on other candidate genes. After applying several filters, 12 relevant high-risk variants have been selected. Our results showed that these variants seem to be inherited in a family specific model. This hypothesis has been confirmed following a thorough analysis of the reported WES studies. Enriched biological process and protein-protein interaction networks resulted in the identification of four novel breast cancer candidate genes namely MMS19, DNAH3, POLK and KATB6. Conclusions: In this first WES application on Tunisian breast cancer patients, we highlighted the impact of next generation sequencing technologies in the identification of novel breast cancer candidate genes which may bring new insights into the biological mechanisms of breast carcinogenesis. Our findings showed that the breast cancer predisposition in non-BRCA families may be ethnic and/or family specific. Farshad; Torabizadeh, Zhila; Haghshenas, Mohammadreza; Sangsefidi,
Hadi Relationship between Human Papilloma Virus and
Colorectal Cancer in Northern Iran MIDDLE EAST JOURNAL OF
CANCER English Article
Colorectal cancer; Human papilloma virus; PCR
COLON; INFECTION; ASSOCIATION; DNA; CARCINOMAS; FREQUENCY
Background: Colorectal cancer is one of the most common
malignancies worldwide with more than one million new cases.
According to the Ministry of Health and Medical Education of Iran,
colorectal cancer is the third most common cancer in Iran. Many
risk factors are known causes of this disease. However, the
molecular mechanisms associated with colorectal cancer are still
under investigation. Recent studies have shown that some viruses,
particularly human papilloma virus, may be associated with the
pathology of colorectal cancer. Methods: This case-control study
examined 95 colorectal cancer and 95 normal colon tissue paraffin
blocks (control) to identify the relationship between human
papilloma virus and colorectal cancer by polymerase chain
reaction. Results: Clinicopathological data that included sex,
age, tumor grade, stage and location were recorded. All tumor and
control groups (totally: 190 samples) were negative in terms of
the human papilloma virus genome. No relationship between
clinicopathological data and human papilloma virus genome was
identified. Conclusions: Regardless of other risk factors for
colorectal cancer, a number of studies in different parts of the
world have shown that human papilloma virus may be an important
factor in the increasing incidence of colorectal cancer. However,
we have found no association between human papilloma virus and
colorectal cancer in this study. [Nosrati, Anahita; Naghshvar,

D. Urban-rural differences in breast cancer

incidence in Egypt (1999-2006) BREAST English

Article Breast cancer;

Incidence; Urban-rural; xenoestrogens; Egypt PERSISTENT ORGANIC

POLLUTANTS; PASSIVE AIR SAMPLERS; BISPHENOL-A; ORGANOCHLORINE

PESTICIDES; POLYCHLORINATED-BIPHENYLS; US POPULATION; WASTE-WATER;

ENVIRONMENT; EXPOSURE; MORTALITY Objective: To describe urban

rural differences in breast cancer incidence in Gharbiah, Egypt

and to investigate if these differences could be explained by

known risk factors of breast cancer. Methods: We used data from

the population-based cancer registry of Gharbiah, Egypt to assess

breast cancer incidence from 1999 through 2006. The Egyptian

census provided data on district-specific population, age, and

urban rural classification. Incidence patterns of breast cancer by

district and age-specific urban rural differences were analyzed.

Results: Overall, incidence rate of breast cancer was three to

four times higher in urban areas than in rural areas (60.9/10(5)-

year for urban areas versus 17.8/10(5)-year for rural areas; IRR =

3.73, 95% CI = 3.30, 4.22). Urban areas had consistently higher

incidence of breast cancer across all age-groups for all years.

Higher incidence of breast cancer was also seen in the more

developed districts of Tanta and El-Mehalla. Conclusions: Higher

incidence of breast cancer in urban and more developed populations

might be related to higher exposure to xenoestrogens, as well as

other endocrine disruptors and genotoxic substances. (C) 2010

Shadmani, Fatemeh; Mansori, Kamyar; Khazaei, Zaher; Moradpour,
Farhad; Varse, Fatemeh Trends in Cervical Cancer
Incidence in Iran from 2003 to 2009 MIDDLE EAST JOURNAL OF
CANCER English Article

Cervical cancer; Trend of incidence; Epidemiology
HUMAN-PAPILLOMAVIRUS; ORAL-CONTRACEPTIVES; CYTOLOGY; RISK;
NEOPLASIA; HISTORY; BREAST; CELLS Background: Cancer is the second
leading cause of death worldwide and the third in Iran. Among
cancers, cervical cancer is the third leading cause of death in
women. Thus, recognizing the epidemiology and trends of cervical
cancer can be effective for planning and policy-making. This study
aims to investigate the incidence and trends of cervical cancer in
Iran due to the few studies that have addressed this issue and the
unclear trend for cervical cancer in Iran. Methods: This study re-
analyzed existing data from the cancer data recording system in
Iran during years 2003 to 2009. We used available data from the
National Cancer Registry and Center for Disease Control of the
Ministry of Health, Treatment and Medical Education. Stata
software (version 11) was used for data analysis and the
significance of the incidence trend diagram was derived with
WINPEPI software. Results: Assessment of the National Cancer

Registry statistics from 2003 to 2009 showed an increased trend in cervical cancer from 2003 to 2008 and a decreased trend from 2008 to 2009. During this period, there were 4273 cases of cervical cancer registered. From these, 394 cases were registered in 2003 which peaked at 907 cases in 2009. The registered cancer cases had an approximately 3-fold increase during this period. Most provinces reported an increased trend of incidence in cervical cancer. Conclusion: Based on the results of this study, the incidence of cervical cancer is increasing in Iran, especially in the central regions of the country. Therefore, considering the growing trend of cancer, we recommend early detection through screening programs, public awareness, and public training programs that particularly target high risk populations.  Stop Hypertension (DASH) diets and colorectal cancer AMERICAN
 JOURNAL OF CLINICAL NUTRITION English Article
 NIH-AARP DIET; CORONARY-
 HEART-DISEASE; IGF-BINDING-PROTEINS; GROWTH-FACTOR-I; C-PEPTIDE;
 RISK; INSULIN; QUESTIONNAIRE; METAANALYSIS; ADHERENCE

Background Although the Mediterranean diet has been studied for cancer mortality and the Dietary Approaches to Stop Hypertension (DASH) diet shares similarities with the Mediterranean diet few studies have specifically examined these 2 diets and incident colorectal cancer Objective The objective was to prospectively assess the association between the Alternate Mediterranean Diet (aMed) and the DASH style diet scores and risk

of colorectal cancer in middle aged men and women Design A total of 87 256 women and 45 490 men (age 30-55 y for women and 40-75 y for men at baseline) without a history of cancer were followed for ≤ 26 y The aMed and DASH scores were calculated for each participant by using dietary information that was assessed ≤ 7 times during follow up Relative risks (RRs) for colorectal cancer were computed with adjustment for potential confounders Results We documented 1432 cases of incident colorectal cancer among women and 1032 cases in men Comparing top with bottom quintiles of the DASH score the pooled RR for total colorectal cancer was 0.80 (95% CI 0.70-0.91 P for trend = 0.0001) The corresponding RR for DASH score and colon cancer was 0.81 (95% CI 0.69-0.95 P for trend = 0.002) There was a suggestion of an inverse association with rectal cancer with a pooled RR-of 0.73 (95% CI 0.55-0.98 P for trend = 0.31) when comparing top with bottom quintiles of DASH score No association was observed with aMed score Conclusion Adherence to the DASH diet (which involves higher intakes of whole grains fruit and vegetables moderate amounts of low fat dairy and lower amounts of red or processed meats desserts and sweetened beverages) was associated with a lower risk of colorectal cancer Am J Clin Nutr 2010 92 1429-35 [Fung, Teresa T.] Simmons Coll, Dept Nutr, Boston, MA 02115 USA; [Fung, Teresa T.; Hu, Frank B.; Wu, Kana; Chiuve, Stephanie E.; Giovannucci, Edward] Harvard Univ, Sch Publ Hlth, Dept Nutr, Boston, MA 02115 USA; [Hu, Frank B.; Giovannucci, Edward] Harvard Univ, Sch Publ Hlth, Dept Epidemiol, Boston, MA 02115 USA; [Fuchs, Charles S.] Dana Farber Canc Inst, Boston, MA 02115 USA; [Hu, Frank B.; Giovannucci, Edward] Brigham & Womens Hosp, Dept Med, Channing Lab, Boston, MA USA; [Chiuve, Stephanie E.] Brigham & Womens Hosp, Dept Med, Div Prevent Med, Boston, MA USA; Harvard Univ, Sch Med, Boston, MA USA Simmons University; Harvard University; Harvard T.H. NBCS Collaborators; kConFab Investigators Spectrum and Frequency of Germline FANCM Protein-Truncating Variants in 44,803 European Female Breast Cancer Cases
CANCERS English Article

breast cancer predisposition; breast cancer risk factors; FANCM PTVs spectrum; protein truncating variants; PTVs RISK; GENE; C.5791C-GREATER-THAN-T; SUSCEPTIBILITY Simple Summary Mutations in the FANCM gene may cause a particular type of breast cancer known as ER-negative. In this study, we describe the geographic distribution of 66 different FANCM mutations identified in 44,803 female breast cancer cases from Europe, USA, Canada and Australia. We found that the FANCM:p.Gln1701* mutation is most common in Northern Europe and has lower frequencies in Southern European countries. In contrast, the FANCM:p.Gly1906Alafs*12 mutation is most common in Southern Europe and rarer in Central and Northern Europe. We found that the FANCM:p.Arg658* mutation is most prevalent in Central Europe and that the FANCM:p.Gln498Thrfs*7 mutation originates from Lithuania. Finally, we showed that many and varied FANCM mutations are present in Southwestern and Central Europeans while a much more limited range of mutations is present in Northeastern Europeans. The knowledge of this geographic distribution of FANCM mutations is important to establish more efficient genetic testing strategies in specific

populations. FANCM germline protein truncating variants (PTVs) are moderate-risk factors for ER-negative breast cancer. We previously described the spectrum of FANCM PTVs in 114 European breast cancer cases. In the present, larger cohort, we report the spectrum and frequency of four common and 62 rare FANCM PTVs found in 274 carriers detected among 44,803 breast cancer cases. We confirmed that p.Gln1701* was the most common PTV in Northern Europe with lower frequencies in Southern Europe. In contrast, p.Gly1906Alafs*12 was the most common PTV in Southern Europe with decreasing frequencies in Central and Northern Europe. We verified that p.Arg658* was prevalent in Central Europe and had highest frequencies in Eastern Europe. We also confirmed that the fourth most common PTV, p.Gln498Thrfs*7, might be a founder variant from Lithuania. Based on the frequency distribution of the carriers of rare PTVs, we showed that the FANCM PTVs spectra in Southwestern and Central Europe were much more heterogeneous than those from Northeastern Europe. These findings will inform the development of more efficient FANCM genetic testing strategies for breast cancer cases from specific European populations. This study was supported by Associazione Italiana Ricerca sul Cancro (AIRC; IG22860) to Paolo Peterlongo and by a fellowship from Fondazione Umberto Veronesi to Gisella Figlioli. BCAC is funded by the European Union's Horizon 2020 Research and Innovation Programme (grant numbers 634935 and 633784 for BRIDGES and B-CAST, respectively), and the PERSPECTIVE I&I project, funded by the Government of Canada through Genome Canada and the Canadian Institutes of Health Research, the Ministère de l'Économie et de l'Innovation du Québec through Genome Québec, the Quebec Breast Cancer Foundation. The EU Horizon 2020 Research and Innovation Programme funding source had no role in study design, data collection, data analysis, data interpretation or writing of the report. Additional funding for BCAC is provided via the Confluence project which is funded with intramural funds from the National Cancer Institute Intramural Research Program, National Institutes of Health. The BRIDGES panel sequencing was supported by the European Union Horizon 2020 research and innovation program BRIDGES (grant number, 634935) and the Wellcome Trust (v203477/Z/16/Z). The ABCS study was supported by the Dutch Cancer Society [grants NKI 2007-3839; 2009 4363] and an institutional grant of the Dutch Cancer Society and of the Dutch Ministry of Health, Welfare and Sport. The work of the BBCC was partly funded by ELAN-Fond of the University Hospital of Erlangen. For BIGGS, ES is supported by NIHR Comprehensive Biomedical Research Centre, Guy's & St. Thomas' NHS Foundation Trust in partnership with King's College London, United Kingdom. IT is supported by the Oxford Biomedical Research Centre. The BREast Oncology Galician Network (BREOGAN) is funded by Accion Estrategica de Salud del Instituto de Salud Carlos III FIS PI12/02125/Cofinanciado and FEDER PI17/00918/Cofinanciado FEDER; Accion Estrategica de Salud del Instituto de Salud Carlos III FIS Intrasalud (PI13/01136); Programa Grupos Emergentes, Cancer Genetics Unit, Instituto de Investigacion Biomedica Galicia Sur. Xerencia de Xestion Integrada de Vigo-SERGAS, Instituto de Salud Carlos III, Spain; Grant 10CSA012E, Conselleria de Industria Programa Sectorial de Investigacion Aplicada, PEME I + D e I + D Suma del Plan Gallego de Investigacion, Desarrollo e Innovacion Tecnologica de la Conselleria de Industria de la Xunta de Galicia, Spain; Grant EC11-192. Fomento de la Investigacion Clinica Independiente, Ministerio de Sanidad, Servicios Sociales e Igualdad, Spain; and Grant FEDER-Innterconecta. Ministerio de Economia y Competitividad, Xunta de Galicia, Spain. The BSUCH study was supported by the Dietmar-Hopp Foundation, the Helmholtz Society

and the German Cancer Research Center (DKFZ). The CAMA study was funded by Consejo Nacional de Ciencia y Tecnologia (CONACyT) (SALUD-2002-C01-7462). Sample collection and processing was funded in part by grants from the National Cancer Institute (NCI R01CA120120 and K24CA169004). CCGP is supported by funding from the University of Crete. The CECILE study was supported by Fondation de France, Institut National du Cancer (INCa), Ligue Nationale contre le Cancer, Agence Nationale de Securite Sanitaire, de l'Alimentation, de l'Environnement et du Travail (ANSES), Agence Nationale de la Recherche (ANR). The CGPS was supported by the Chief Physician Johan Boserup and Lise Boserup Fund, the Danish Medical Research Council and Herlev and Gentofte Hospital. The CNIO-BCS was supported by the Instituto de Salud Carlos III, the Red Tematica de Investigacion Cooperativa en Cancer and grants from the Asociacion Espanola Contra el Cancer and the Fondo de Investigacion Sanitario (PI11/00923 and PI12/00070). FHRISK and PROCAS are funded from NIHR grant PGfAR 0707-10031. DGE, AH and WGN are supported by the NIHR Manchester Biomedical Research Centre (IS-BRC-1215-20007). The GC-HBOC (German Consortium of Hereditary Breast and Ovarian Cancer) is supported by the German Cancer Aid (grant no 110837 and 70114178, coordinator: Rita K. Schmutzler, Cologne) and the Federal Ministry of Education and Research, Germany (grant no 01GY1901). This work was also funded by the European Regional Development Fund and Free State of Saxony, Germany (LIFE-Leipzig Research Centre for Civilization Diseases, project numbers 713-241202, 713-241202, 14505/2470, 14575/2470). The GENICA was funded by the Federal Ministry of Education and Research (BMBF) Germany grants 01KW9975/5, 01KW9976/8, 01KW9977/0 and 01KW0114, the Robert Bosch Foundation, Stuttgart, Deutsches Krebsforschungszentrum (DKFZ), Heidelberg, the Institute for Prevention and Occupational Medicine of the German Social Accident Insurance, Institute of the Ruhr University Bochum (IPA), Bochum, as well as the Department of Internal Medicine, Johanniter GmbH Bonn, Johanniter Krankenhaus, Bonn, Germany. Generation Scotland (GENSCOT) received core support from the Chief Scientist Office of the Scottish Government Health Directorates [CZD/16/6] and the Scottish Funding Council [HR03006]. Genotyping of the GS:SFHS samples was carried out by the Genetics Core Laboratory at the Edinburgh Clinical Research Facility, University of Edinburgh, Scotland and was funded by the Medical Research Council UK and the Wellcome Trust (Wellcome Trust Strategic Award "STratifying Resilience and Depression Longitudinally" (STRADL) Reference 104036/Z/14/Z). Funding for identification of cases and contribution to BCAC funded in part by the Wellcome Trust Seed Award "Temporal trends in incidence and mortality of molecular subtypes of breast cancer to inform public health, policy and prevention" Reference 207800/Z/17/Z. The GESBC was supported by the Deutsche Krebshilfe e. V. [70492] and the German Cancer Research Center (DKFZ). The HABCS study was supported by German Research Foundation (DFG Do761/15-1), the Claudia von Schilling Foundation for Breast Cancer Research, by the Lower Saxonian Cancer Society, and by the Rudolf Bartling Foundation. The HEBCS was financially supported by the Helsinki University Hospital Research Fund, the Sigrid Juselius Foundation and the Cancer Foundation Finland. The HEBON study is supported by the Dutch Cancer Society grants NKI1998-1854, NKI2004-3088, NKI2007-3756, NKI 12535, the Netherlands Organisation of Scientific Research grant NWO 91109024, the Pink Ribbon grants

110005 and 2014-187.WO76, the BBMRI grant NWO 184.021.007/CP46, and the Transcan grant JTC 2012 Cancer 12-054. The HMBCS was supported by the German Research Foundation (DFG Do761/151), a grant from the Friends of Hannover Medical School, and by the Rudolf Bartling Foundation. The HUBCS was supported by German Research Foundation (DFG Do761/15-1), a grant from the German Federal Ministry of Research and Education (RUS08/017), B.M. was supported by grant 17-44-020498, 17-29-06014 of the Russian Foundation for Basic Research, D.P. was supported by grant 18-29-09129 of the Russian Foundation for Basic Research, E.r K was supported by the mega grant from the Government of Russian Federation (2020-220-08-2197), and the study was performed as part of the assignment of the Ministry of Science and Higher Education of the Russian Federation (No AAAAA-16-116020350032-1). Financial support for KARBAC was provided through the regional agreement on medical training and clinical research (ALF) between Stockholm County Council and Karolinska Institutet, the Swedish Cancer Society, The Gustav V Jubilee foundation and Bert von Kantzows foundation. The KARMA study was supported by Marit and Hans Rausings Initiative Against Breast Cancer. The KBCP was financially supported by the special Government Funding (VTR) of Kuopio University Hospital grants, Cancer Fund of North Savo, the Finnish Cancer Organizations and by the strategic funding of the University of Eastern Finland. kConFab was supported by a grant from the National Breast Cancer Foundation, and previously by the National Health and Medical Research Council (NHMRC), the Queensland Cancer Fund, the Cancer Councils of New South Wales, Victoria, Tasmania and South Australia and the Cancer Foundation of Western Australia. Financial support for the AOCS was provided by the United States Army Medical Research and Materiel Command [DAMD17-01-1-0729], Cancer Council Victoria, Queensland Cancer Fund, Cancer Council New South Wales, Cancer Council South Australia, The Cancer Foundation of Western Australia, Cancer Council Tasmania and the National Health and Medical Research Council of Australia (NHMRC; 400413, 400281, 199600). G.C.T. and P.W. were supported by the NHMRC. RB was a Cancer Institute NSW Clinical Research Fellow. The MARIE study was supported by the Deutsche Krebshilfe e.V. [70-2892-BR I, 106332, 108253, 108419, 110826, 110828], the Hamburg Cancer Society, the German Cancer Research Center (DKFZ) and the Federal Ministry of Education and Research (BMBF) Germany [01KH0402]. The MASTOS study was supported by "Cyprus Research Promotion Foundation" grants 0104/13 and 0104/17, and the Cyprus Institute of Neurology and Genetics. MBCSG is supported by grants from the Italian Association for Cancer Research (AIRC). The Melbourne Collaborative Cohort Study (MCCS) cohort recruitment was funded by VicHealth and Cancer Council Victoria. The MCCS was further augmented by Australian National Health and Medical Research Council grants 209057, 396414 and 1074383 and by infrastructure provided by Cancer Council Victoria. Cases and their vital status were ascertained through the Victorian Cancer Registry and the Australian Institute of Health and Welfare, including the National Death Index and the Australian Cancer Database. The NBCS has received funding from the K.G. Jebsen Centre for Breast Cancer Research; the Research Council of Norway grant 193387/V50 (to A-L Borresen-Dale and V.N. Kristensen) and grant 193387/H10 (to A-L Borresen-Dale and V.N. Kristensen), South Eastern Norway Health Authority (grant 39346 to A-L Borresen-Dale) and the Norwegian Cancer Society (to A-L Borresen-

Dale and V.N. Kristensen). The NBHS was supported by NIH grant R01CA100374. Biological sample preparation was conducted the Survey and Biospecimen Shared Resource, which is supported by P30 CA68485. The Ontario Familial Breast Cancer Registry (OFBCR) was supported by grant U01CA164920 from the USA National Cancer Institute of the National Institutes of Health. The content of this manuscript does not necessarily reflect the views or policies of the National Cancer Institute or any of the collaborating centers in the Breast Cancer Family Registry (BCFR), nor does mention of trade names, commercial products, or organizations imply endorsement by the USA Government or the BCFR. The PBCS was funded by Intramural Research Funds of the National Cancer Institute, Department of Health and Human Services, USA.

Genotyping for PLCO was supported by the Intramural Research Program of the National Institutes of Health, NCI, Division of Cancer Epidemiology and Genetics. The PLCO is supported by the Intramural Research Program of the Division of Cancer Epidemiology and Genetics and supported by contracts from the Division of Cancer Prevention, National Cancer Institute, National Institutes of Health. The RBCS was funded by the Dutch Cancer Society (DDHK 2004-3124, DDHK 2009-4318). The SASBAC study was supported by funding from the Agency for Science, Technology and Research of Singapore (A*STAR), the US National Institute of Health (NIH) and the Susan G. Komen Breast Cancer Foundation. SEARCH was funded by Cancer Research UK [C490/A10124, C490/A16561] and supported by the UK National Institute for Health Research Biomedical Research Centre at the University of Cambridge. The University of Cambridge has received salary support for PDPP from the NHS in the East of England through the Clinical Academic Reserve. SKKDKFZS was supported by the DKFZ. The SZBCS was supported by Grant PBZ_KBN_122/P05/2004 and the program of the Minister of Science and Higher Education under the name "Regional Initiative of Excellence" in 2019-2022 project number 002/RID/2018/19 amount of financing 12,000,000 PLN. UBCS was supported by funding from National Cancer Institute (NCI) grant R01 CA163353 (to N.J. Camp) and the Women's Cancer Center at the Huntsman Cancer Institute (HCI). Data collection for UBCS was supported by the Utah Population Database (UPDB) and Utah Cancer Registry (UCR). Partial support for all datasets within the UPDB was provided by the University of Utah HCI and the HCI Cancer Center Support grant, P30 CA2014 from the NCI. The UCR is funded by the NCI's SEER Program, Contract No. HHSN261201800016I, the US Centers for Disease Control and Prevention's National Program of Cancer Registries, Cooperative Agreement No. NU58DP006320, with additional support from the University of Utah and Huntsman Cancer Foundation.

cancer among women with rising incidence of cervical cytological abnormalities. The unlearned lesson EUROPEAN JOURNAL OF GYNAECOLOGICAL ONCOLOGY English Article

Pap smear; Cervical cancer; HPV; Cervical screening program; Jordan EXTENDED MIDDLE-EAST; HUMAN-PAPILLOMAVIRUS; NORTH-AFRICA; PAP-SMEAR; PREVENTION; ADENOCARCINOMA; KNOWLEDGE Objectives: Cervical cancer is preceded by a group of epithelial cell abnormalities. However, there is insufficient data on cervical abnormalities in Jordan and the Middle East at large. The current study aimed at determining the prevalence of different cytological abnormalities in women in Jordan. In addition, it aimed at assessing the age specific cytological abnormalities in these women and analyzing the changing trends of epithelial cell abnormalities in cervical smear over a period of 15 years compared in three periods of five years each. Materials and Methods: 6,455 conventional cervical Papanicolaou (Pap) smear results obtained between January 2000 and December 2014 were retrospectively analyzed. Results: Out of the 6,454 Pap smears analyzed, 5,645 (87.5%) were found adequate for reporting. A total number of 801 (14.2 %) cases had cervical epithelial abnormalities. A significant increase in cytological abnormalities was observed between 2000 and 2014. In addition, a significant increasing trend in cervical cytological abnormalities was noted between 2000 and 2014. The highest percentage of cytological abnormalities (20.1%) was found in women younger than 25 years old. In all of the age groups, the low-grade squamous intraepithelial lesions (LSIL) cytological abnormality was the most prevalent. Conclusions: Invasive cervical cancer is still a killer for young women in the developing countries. The present study may reflect a change in the sociosexual behavior over the last 15 years. The current work highlights the importance of awareness campaigns on the importance of cervical smear and the urgent need for initiating a cervical screening program in Jordan.

Drozdowski, Marek; Chadzynski, Tomasz Associations of
Dietary Patterns and Metabolic-Hormone Profiles with Breast Cancer
Risk: A Case-Control Study NUTRIENTS English
Article breast cancer;

dietary pattern; Mediterranean diet; hormones; metabolic syndrome
MEDITERRANEAN DIET; CHOLESTEROL; PROLACTIN; COHORT; SERUM;
ADHERENCE; ESTROGEN; INSULIN; OBESITY Breast cancer is the most
diagnosed cancer in women worldwide. Studies regarding complex
breast cancer aetiology are limited and the results are
inconclusive. We investigated the associations between dietary
patterns (DPs), metabolic-hormone profiles (M-HPs), and breast
cancer risk. This case-control study involved 420 women aged 40-79
years from north-eastern Poland, including 190 newly-diagnosed
breast cancer cases. The serum concentration of lipid components,
glucose, and hormones (oestradiol, progesterone, testosterone,
prolactin, cortisol, insulin) was marked in 129 post-menopausal
women (82 controls, 47 cases). The food frequency consumption was
collected using a validated 62-item food frequency questionnaire.
A posteriori DPs or M-HPs were derived with a Principal Component
Analysis (PCA). Three DPs: Non-Healthy', Prudent', and Margarine
and Sweetened Dairy' and two M-HPs: Metabolic-Syndrome' and High-
Hormone' were identified. The Polish-adapted Mediterranean Diet'
(Polish-aMED') score was calculated. The risk of breast cancer
risk was three-times higher (odds ratio (OR): 2.90; 95% confidence
interval (95% CI): 1.62-5.21; $p < 0.001$) in the upper tertile of
the Non-Healthy' pattern (reference: bottom tertile) and five-
times higher (OR: 5.34; 95% CI: 1.84-15.48; $p < 0.01$) in the upper
tertile of the High-Hormone' profile (reference: bottom tertile).
There was a positive association of Metabolic-Syndrome' profile
and an inverse association of Polish-aMED' score with the risk of
breast cancer, which disappeared after adjustment for confounders.
No significant association between Prudent' or Margarine and
Sweetened Dairy' DPs and cancer risk was revealed. Concluding, a
pro-healthy diet is insufficient to reduce the risk of breast
cancer in peri- and postmenopausal women. The findings highlight
the harmful effect of the High-Hormone' profile and the Non-
Healthy' dietary pattern on breast cancer risk. In breast cancer
prevention, special attention should be paid to decreasing the
adherence to the Non-Healthy' pattern by reducing the consumption
of highly processed food and foods with a high content of sugar
and animal fat. There is also a need to monitor the concentration
of multiple sex hormones in the context of breast cancer risk.

Evaluating the Effects of an Organic Extract from the Mediterranean Sponge *Geodia cydonium* on Human Breast Cancer Cell Lines INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES

English Article breast

cancer; cytotoxicity; metabolomics; cytokines; sponges CARIBBEAN SPONGE; NATURAL-PRODUCTS; ANTITUMOR; METABOLISM; NUCLEOSIDES; PATHWAY

Marine sponges are an excellent source of bioactive secondary metabolites for pharmacological applications. In the present study, we evaluated the chemistry, cytotoxicity and metabolomics of an organic extract from the Mediterranean marine sponge *Geodia cydonium*, collected in coastal waters of the Gulf of Naples. We identified an active fraction able to block proliferation of breast cancer cell lines MCF-7, MDA-MB231, and MDA-MB468 and to induce cellular apoptosis, whereas it was inactive on normal breast cells (MCF-10A). Metabolomic studies showed that this active fraction was able to interfere with amino acid metabolism, as well as to modulate glycolysis and glycosphingolipid metabolic pathways. In addition, the evaluation of the cytokinome profile on the polar fractions of three treated breast cancer cell lines (compared to untreated cells)

demonstrated that this fraction induced a slight anti-inflammatory effect. Finally, the chemical entities present in this fraction were analyzed by liquid chromatography high resolution mass spectrometry combined with molecular networking. [Costantini,

GEICAM Spanish Mediterranean diet and other dietary
 patterns and breast cancer risk: case-control EpiGEICAM study
 BRITISH JOURNAL OF CANCER English Article
 breast neoplasms; dietary
 patterns; aMED; AHEI; principal component analysis; Mediterranean
 pattern PLASMA-CONCENTRATIONS; MULTIPLE IMPUTATION; OLIVE OIL;
 WOMEN; METAANALYSIS; REPRODUCIBILITY; CONSUMPTION; ADHERENCE;
 VALIDITY; QUALITY Background: Although there are solid

findings regarding the detrimental effect of alcohol consumption, the existing evidence on the effect of other dietary factors on breast cancer (BC) risk is inconclusive. This study aimed to evaluate the association between dietary patterns and risk of BC in Spanish women, stratifying by menopausal status and tumour subtype, and to compare the results with those of Alternate Healthy Index (AHEI) and Alternate Mediterranean Diet Score (aMED). Methods: We recruited 1017 incident BC cases and 1017 matched healthy controls of similar age ($\pm$ 5 years) without a history of BC. The association between 'a priori' and 'a posteriori' developed dietary patterns and BC in general and according to menopausal status and intrinsic tumour subtypes (ER+/PR+ and HER2-; HER2+; and ER-/PR- and HER2-) was evaluated using logistic and multinomial regression models. Results: Adherence to the Western dietary pattern was related to higher risk of BC (OR for the top vs the bottom quartile 1.46 (95% CI 1.06-2.01)), especially in premenopausal women (OR = 1.75; 95% CI 1.14-2.67). In contrast, the Mediterranean pattern was related to a lower risk (OR for the top quartile vs the bottom quartile 0.56 (95% CI 0.40-0.79)). Although the deleterious effect of the Western pattern was similarly observed in all tumour subtypes, the protective effect of our Mediterranean pattern was stronger for triple-negative tumours (OR = 0.32; 95% CI 0.15-0.66 and P-heterogeneity = 0.04). No association was found between adherence to the Prudent pattern and BC risk. The associations between 'a priori' indices and BC risk were less marked (OR for the top vs the bottom quartile of AHEI = 0.69; 95% CI 0.51-0.94 and aMED = 0.74; 95% CI 0.46-1.18)). Conclusions: Our results confirm the harmful effect of a Western diet on BC risk, and add new evidence on the benefits of a diet rich in fruits, vegetables, legumes, oily fish and vegetable oils for preventing all BC subtypes, and particularly triple-negative tumours. Diet Quality Scores Inversely Associated with Postmenopausal Breast Cancer Risk Are Not Associated with Premenopausal Breast Cancer Risk in the California Teachers Study
JOURNAL OF NUTRITION English Article

diet quality; diet pattern; aMED; AHEI-2010; DASH; Paleolithic index; breast cancer MEDITERRANEAN DIET; PATTERN SCORES; ADHERENCE; METAANALYSIS; CONSUMPTION; INDEXES; COHORT; WOMEN Background: Evidence for the association

between diet and breast cancer risk is inconsistent. Thus, research that compares indexes of overall diet quality may provide new insight. Objective: We examined the association between diet quality indexes and pre- and postmenopausal breast cancer risk in a large prospective cohort. Methods: This was a prospective analysis of 96,959 women, aged 22-104 y, in the California Teachers Study cohort (1995-2011). Diet quality was characterized by 4 different indexes. Specifically, we examined Alternate Mediterranean Diet (aMED), Alternative Healthy Eating Index-2010 (AHEI-2010), Dietary Approaches to Stop Hypertension (DASH), and Paleolithic index (PALEO) scores with the risk of developing breast cancer. We used multivariable Cox proportional hazards regression models to derive HRs and 95% CIs for breast cancer risk. Results: In the analysis of 42,517 women at risk of premenopausal breast cancer, there was no association between any of the indexes and incident breast cancer (346 cases). In the analysis of 54,442 women at risk of postmenopausal breast cancer at baseline, higher AHEI-2010, aMED, and DASH scores were inversely associated with incident breast cancer (3523 incident cases). Respectively, HRs (95% CIs) comparing quintile 5 to quintile 1 (reference) for AHEI-2010, aMED, and DASH indexes were 0.87 (0.78, 0.97; P-trend = 0.004), 0.91 (0.82, 1.02; P-trend = 0.03), and 0.89 (0.80, 1.00; P-trend = 0.03). The PALEO score was not associated with postmenopausal breast cancer (HR for quintile 5 compared with quintile 1: 1.05; 95% CI: 0.94, 1.17).

Conclusions: Diet quality indexes that emphasize intake of whole grains, vegetables, fruits, legumes, and nuts and seeds and de-emphasize red and processed meats and sugar-sweetened beverages were modestly associated with a lower risk of incident postmenopausal breast cancer risk. However, they were not associated with premenopausal breast cancer, and the PALEO score was not associated with cancer risk regardless of menopausal status.

Mediterranean Diet and Breast Density in the Minnesota
Breast Cancer Family Study NUTRITION AND CANCER-AN INTERNATIONAL
JOURNAL English Article

MAMMOGRAPHIC PARENCHYMAL PATTERNS; POSTMENOPAUSAL
WOMEN; FOLLOW-UP; RISK; COHORT; POPULATION; ESTROGEN; SURVIVAL;
TRIAL; FAT Mediterranean populations' lower breast cancer
incidence has been attributed to a traditional Mediterranean diet,
but few studies have quantified Mediterranean dietary pattern
intake in relation to breast cancer. We examined the association
of a Mediterranean diet scale (MDS) with mammographic breast
density as a surrogate marker for breast cancer risk. Participants
completed a dietary questionnaire and provided screening
mammograms for breast density assessment using a computer-assisted
method. Among 1,286 women, MDS was not clearly associated with
percent density in multivariate linear regression analyses.
Because of previous work suggesting dietary effects limited to
smokers, we conducted stratified analyses and found MDS and
percent density to be significantly, inversely associated among
current smokers (beta = -1.68, P = 0.002) but not among nonsmokers
(beta = -0.08, P = 0.72; P for interaction = 0.008). Our results
confirm a previous suggestion that selected dietary patterns may
be protective primarily in the presence of procarcinogenic
compounds such as those found in tobacco smoke. [Tseng,

Article human papillomavirus; vaccine acceptance; vaccine awareness; Middle East; meta-analysis; meta-regression CERVICAL-CANCER; HPV-VACCINATION; UNIVERSITY-STUDENTS; ADOLESCENT GIRLS; RISK-FACTORS; WOMENS KNOWLEDGE; VIRUS INFECTION; FAMILY PHYSICIANS; MOTHERS KNOWLEDGE; NURSING-STUDENTS

Cervical cancer, closely linked to human papillomavirus (HPV) infection, is a major global health concern. Our study aims to fill the gap in understanding HPV vaccine awareness and acceptance in the Middle East, where national immunization programs are often lacking and cultural perceptions hinder acceptance. This systematic review and meta-analysis adhered to Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines. A comprehensive literature search across several databases was conducted on 5 September 2023. We included quantitative studies on HPV vaccine awareness and acceptance in Middle Eastern countries. Data extraction and quality assessment were conducted independently by multiple reviewers to ensure accuracy. Statistical analyses, including subgroup analyses, were performed using R to calculate pooled estimates, assess heterogeneity, and publication bias. We reviewed 159 articles from 15 Middle Eastern countries, focusing on 93,730 participants, predominantly female and healthcare workers. HPV vaccine awareness was found to be 41.7% (95% CI 37.4%-46.1%), with higher awareness among healthcare workers. The pooled acceptance rate was 45.6% (95% CI 41.3%-50.1%), with similar rates between healthcare and non-healthcare workers. Our study highlights the critical need for increased HPV vaccine awareness and acceptance in the Middle East, emphasizing the importance of integrating the vaccine into national immunization programs and addressing cultural and religious factors to improve public health outcomes. J Jarosz, E; Gugushvili, A Jarosz, Ewa;
Gugushvili, Alexi Parental education, health
literacy and children's adult body height JOURNAL OF BIOSOCIAL
SCIENCE English Article

Body height; Parental education; Functional literacy
LABOR-MARKET; BIRTH-WEIGHT; FOLLOW-UP; WOMEN; MORTALITY;
COUNTRIES; STATURE; INEQUALITIES; ASSOCIATION; MIGRATIONHuman
anthropometric traits, while significantly determined by genetic
factors, are also affected by an individual's early life
environment. An adult's body height is a valid indicator of their
living conditions in childhood. Parental education has been shown
to be one of the key covariates of individuals' health and height,
both in childhood and adulthood. Parental functional literacy has
been demonstrated to be another important determinant of child
health, but this has largely been overlooked in studies on height.
The objective of this study was to analyse the associations
between parents' education, their functional literacy and their
children's adult body height. The study used data for 39,240
individuals from the 2016 wave of the nationally representative
Life in Transition Survey (LITS) conducted in 34 countries in
Southern and Eastern Europe, the Middle East and Central Asia.
Using linear and Poisson models, regression adjustment treatment
estimators and multilevel mixed-effects linear regressions, the
study analysed the links between mother's and father's educational
attainment, parental functional literacy, measured by the number
of books in the childhood home, and children's adult height. The
models also included other individual and contextual covariates of
height. The results demonstrated that mother's educational
attainment and parental functional literacy have independent
associations with children's adult body height. Sufficient
literacy skills of the parent may have a positive effect on
children's growth even if parental education is low. These
associations remained significant across time. The study also
provides evidence of a widening of the height gap for men born in
the period just before and after systemic transition in post-
socialist societies, which may suggest an increase in social
differences in early living standards. [Jarosz, Ewa] Polish Acad

 D. Urban-rural differences in breast cancer
 incidence by hormone receptor status across 6 years in Egypt
 BREAST CANCER RESEARCH AND TREATMENT English
 Article Breast cancer
 incidence; Hormone receptor status; Mammary stem cells;
 Xenoestrogens; Egypt PERSISTENT ORGANIC POLLUTANTS; ESTROGEN-
 RECEPTOR; RISK-FACTORS; ENVIRONMENTAL-POLLUTANTS; BISPHENOL-A;
 STEM-CELLS; EPIDEMIOLOGY; TUMOR; IDENTIFICATION; POPULATION
 Breast cancer incidence is higher in developed countries
 with higher rates of estrogen receptor positive (ER+) tumors. ER+
 tumors are caused by estrogenic exposures although known exposures
 explain approximately 50% of breast cancer risk. Unknown risk
 factors causing high breast cancer incidence exist that are
 estrogenic and development-related. Xenoestrogens are such risk
 factors but are difficult to study since developed countries lack
 unexposed populations. Developing countries have urban-rural
 populations with differential exposure to xenoestrogens. This
 study assessed urban-rural breast cancer incidence classified by
 hormone receptor status using data from Gharbiah population-based
 cancer registry in Egypt from 2001 to 2006. Urban ER+ incidence
 rate (per 100,000 women) was 2-4 times (IRR = 3.36, 95% CI = 4.84,
 2.34) higher than rural incidence rate. ER-incidence rate was 2-3
 times (IRR = 1.86, 95% CI = 2.38, 1.45) higher in urban areas than
 in rural areas. Our findings indicate that urban women may
 probably have a higher exposure to xenoestrogens. [Dey, Subhojit;

Tsui, Jennifer; Saraiya, Mona; Thompson, Trevor;
Dey, Achintya; Richardson, Lisa Cervical cancer
screening among foreign-born women by birthplace and duration in
the United States JOURNAL OF WOMENS HEALTH

English Article; Proceedings Paper 14th Annual Congress
on Womens Health JUN 03-06, 2006 Hilton Head Isl, SC

HUMAN-PAPILLOMAVIRUS VACCINE; PACIFIC ISLANDER WOMEN;
HEALTH-INSURANCE; CITIZENSHIP STATUS; BREAST; AMERICAN;

IMMIGRANTS; BEHAVIORS; ATTITUDES; ACCULTURATION Objective: Mortality rates for cervical cancer have increased among foreign-born women in the United States in the last two decades. Previous research indicates that rates of Pap testing are lower among foreign-born women than in U.S.-born women. This study identifies screening rates among foreign-born women by birthplace and duration in the United States. Methods: We used data from 4 years (1998, 1999, 2000, 2003) of the National Health Interview Survey (NHIS) to estimate Pap testing rates by birthplace (Mexico, Central America, Caribbean, South America, Europe, Russia, Africa, Middle East, India, Asia, and Southeast Asia) and percent of lifetime spent in the United States for women aged ≥ 18 years ($n = 70,775$). Rates were age standardized to the 2000 U. S.

population. Results: After adjusting for demographic characteristics and health indicators, we found that 18.6% (95% CI 16.7, 20.6) of recent immigrants ($<25\%$ of lifetime in the United States) and 9.9% (95% CI 9.0, 10.8) of established immigrants ($\geq 25\%$ of lifetime in the United States) never received a Pap test in their lifetime compared with 5.8% (95% CI 5.5, 6.1) of U.S.-born women. Adjusted prevalence of never receiving a Pap test was highest among women from Asia, Southeast Asia, and India (19.6%), South America (12.7%), Mexico (11.2%), Caribbean (11.0%), Europe (9.9%), and Central America (9.2%). Conclusions: Significant differences exist in rates of screening for cervical cancer between foreign-born groups by birthplace and by duration in the United States. Nationally and locally funded screening programs may benefit from these findings in developing screening strategies for foreign-born women.

Recommendation-based dietary indexes and risk of colorectal cancer in the Nurses' Health Study and Health Professionals Follow-up Study AMERICAN JOURNAL OF CLINICAL NUTRITION English Article

colorectal cancer; dietary index; cohort studies; DASH diet; Mediterranean diet; Alternative Healthy Eating Index POLYUNSATURATED FATTY-ACIDS; DASH-STYLE DIET; VITAMIN-D; MEDITERRANEAN DIET; REGRESSION-MODELS; QUALITY INDEXES; POOLED ANALYSIS; CALCIUM INTAKE; COLON-CANCER; RED MEAT Background: Many dietary indexes exist for chronic disease prevention, but the optimal dietary pattern for colorectal cancer prevention is unknown. Objective: We sought to determine associations between adherence to various dietary indexes and incident colorectal cancer in 2 prospective cohort studies. Design: We followed 78,012 women in the Nurses' Health Study and 46,695 men in the Health Professionals Follow-up Study from 1986 and 1988, respectively, until 2012. We created dietary index scores for the Dietary Approaches to Stop Hypertension (DASH) diet, Alternative Mediterranean Diet (AMED), and Alternative Healthy Eating Index-2010 (AHEI-2010) and used Cox regression to estimate HRs and 95% CIs for risk of colorectal cancer (CRC) and by anatomic subsite. We also conducted latency analyses to examine associations between diet and CRC risk during different windows of exposure. We conducted analyses in men and women separately, and subsequently pooled these results in a random-effects meta-analysis. Results: We documented 2690 colorectal cancer cases. Pooled multivariable HRs for colorectal cancer risk comparing the highest to lowest quintile of diet scores were 0.89 (95% CI: 0.74, 1.08; P-trend = 0.10) for DASH, 0.89 (95% CI: 0.73, 1.10; P-trend = 0.31) for AMED, and 0.95 (95% CI: 0.83, 1.09; P-trend = 0.56) for AHEI-2010 (P-heterogeneity ≥ 0.07 for all). In sex-specific analyses, we observed stronger associations in men for all dietary indexes (DASH: multivariable HR = 0.81, 95% CI: 0.66, 0.98; P-trend = 0.003; AMED: multivariable HR = 0.80, 95% CI: 0.65, 0.98; P-trend = 0.02; AHEI-2010: multivariable HR = 0.88, 95% CI: 0.72, 1.07; P-trend = 0.04) than in women (multivariable HRs range from 0.98 to 1.01). Conclusions: Adherence to the DASH, AMED, and AHEI-2010 diets was inversely associated with colorectal cancer risk in men. These diets were not associated with colorectal cancer risk in women.

CHEK2 c.1100delC allele is rarely identified in Greek breast cancer cases CANCER GENETICS English Article

1100delC; BRCA; breast cancer; CHEK2; hereditary TUMOR CHARACTERISTICS; CHEK2-ASTERISK-1100DELC VARIANT; HEREDITARY BREAST; GERMLINE MUTATION; CHK2 KINASE; EARLY-ONSET; SUSCEPTIBILITY; 1100DELC; FAMILIES; GENE The CHEK2 gene encodes a protein kinase that plays a crucial role in maintenance of genomic integrity and the DNA repair mechanism. CHEK2 germline mutations are associated with increased risk of breast cancer and other malignancies. From a clinical perspective, the most significant mutation identified is the c.1100delC mutation, which is associated with an approximately 25% lifetime breast cancer risk. The distribution of this mutation shows wide geographical variation; it is more prevalent in the Northern European countries and less common, or even absent, in Southern Europe. In order to estimate the frequency of the CHEK2 c.1100delC mutation in Greek breast cancer patients, we genotyped 2,449 patients (2,408 females and 41 males), which was the largest series ever tested for c.1100delC. The mean age of female and male breast cancer diagnosis was 49 and 59 years, respectively. All

patients had previously tested negative for the Greek BRCA1 founder and recurrent mutations. The CHEK2 c.1100delC mutation was detected in 0.16% (4 of 2,408) of females, all of whom were diagnosed with breast cancer before the age of 50 years. Only one c.1100delC carrier was reported with breast cancer family history. The present study indicates that the CHEK2 c.1100delC mutation does not contribute substantially to hereditary breast cancer in patients of Greek descent. Associations between overall, healthful, and unhealthful low-fat dietary patterns and breast cancer risk in a Mediterranean cohort: The SUN project

NUTRITION

English

Article

Breast cancer; Cohort; Low -fat diet; Dietary patterns; Prospective cohort study; Epidemiology FOOD-FREQUENCY QUESTIONNAIRE; CARDIOVASCULAR-DISEASE; FOLLOW-UP; VALIDATION; NUTRITION; MORTALITY; INSULIN; INDEX; ACIDS Objectives: Dietary patterns may have a greater influence on human health than individual foods or nutrients, and they are also of substantial interest in the field of breast cancer prevention. Beyond the adequate balance of macronutrients, evidence indicates that the quality of macronutrient sources may play an important role in health outcomes. We sought to examine the relationship between healthful and unhealthful low-fat dietary patterns in relation to breast cancer. Methods: We used observational data from a Mediterranean cohort study (the Seguimiento Universidad de Navarra project). We prospectively followed 10 930 middle-aged women initially free of breast cancer during a median follow-up of 12.1 y. We calculated an overall, an unhealthful, and a healthful low-fat diet score, based on a previously validated 136-item food frequency questionnaire and grouped participants into ter -tiles. Incident breast cancer-overall and stratified by menopausal status-was the primary outcome. It was self-reported by participants and confirmed based on medical reports or consultation of the National Death Index. We used multivariable Cox regression models adjusted for potential confounders. Results: During 123 297 person-years of follow-up, 150 cases of incident breast cancer were confirmed. No signifi-cant associations were observed for overall or premenopausal breast cancer. For postmenopausal women, we observed a significant association for moderate adherence to the unhealthful low-fat dietary score and postmeno-pausal breast cancer (comparing tertile 2 to tertile 1; hazard ratio = 2.18; 95% confidence interval, 1.15-4.13). Conclusions: In conclusion, no clear associations were observed, although more research is needed to address the association between an unhealthful dietary pattern and postmenopausal breast cancer risk.  Human papillomavirus infection in women with and
 without cervical cancer in Tehran, Iran INTERNATIONAL JOURNAL OF
 CANCER English Article
 human papillomavirus; prevalence; cervical cancer;
 Iran REPUBLIC-OF-CHINA; REGISTRY; PREVALENCE; WORLDWIDE; CITYNo
 data exist on the population prevalence of, or risk factors for,
 human papillomavirus (HPV) infection in Iran or the Middle East.
 Cervical specimens were obtained from 825 married women aged 18-59
 years from the general population of Tehran, Iran and from 45
 locally diagnosed invasive cervical cancers (ICC) according to the
 standardized protocol of the International Agency for Research on
 Cancer HPV Prevalence Surveys. HPV was detected and genotyped
 using a GP5+/6+ PCR-based assay. HPV prevalence in the general
 population was 7.8% (95% confidence interval: 6.0-9.8) (5.1% of
 high-risk types), with no significant variation by age. HPV
 positivity was significantly higher among divorced women, women in
 polygamous marriages and those reporting husband's absence from
 home for >7 nights/month. HPV16/18 accounted for 30 and 82.2% of
 HPV-positive women in the general population and ICC,
 respectively. Cervical cancer prevention policies should take into
 account the relatively low HPV prevalence in this population.

Co-Incidence of Epstein-Barr Virus and High-Risk Human Papillomaviruses in Cervical Cancer of Syrian Women FRONTIERS IN ONCOLOGY English Article
Epstein-Barr virus; high-risk human papillomaviruses; cervical cancer; Syrian women; cancer phenotype BREAST-CANCER; TISSUE MICROARRAY; EPITHELIAL-CELLS; HPV TYPE-16; EBV; CARCINOGENESIS; ASSOCIATION; METASTASIS; EXPRESSION; CARCINOMA
Epstein-Barr virus (EBV) has been recently shown to be co-present with high-risk human papillomaviruses (HPVs) in human cervical cancer; thus, these oncoviruses play an important role in the initiation and/or progression of this cancer. Accordingly, our group has recently viewed the presence and genotyping distribution of high-risk HPVs in cervical cancer in Syrian women; our data pointed out that HPVs are present in 42/44 samples (95%). Herein, we aim to explore the co-prevalence of EBV and high-risk HPVs in 44 cervical cancer tissues from Syrian women using polymerase

chain reaction, immunohistochemistry, and tissue microarray analyses. We found that EBV and high-risk HPVs are co-present in 15/44 (34%) of the samples. However, none of the samples was exclusively EBV-positive. Additionally, we report that the co-expression of LMP1 and E6 genes of EBV and high-risk HPVs, respectively, is associated with poorly differentiated squamous cell carcinomas phenotype; this is accompanied by a strong and diffuse overexpression of Id-1 (93% positivity), which is an important regulator of cell invasion and metastasis. These data imply that EBV and HPVs are co-present in cervical cancer samples in the Middle East area including Syria and their co-presence is associated with a more aggressive cancer phenotype. Future investigations are needed to elucidate the exact role of EBV and HPVs cooperation in cervical carcinogenesis. impairment induced by cancer therapy is common and can be long lasting after completion of therapy. Little is known on factors that influence recovery from the impairment. We evaluated the associations of dietary intake and supplement use with post-therapy cognitive recovery in a large cohort of breast cancer survivors. This study included 1047 breast cancer patients aged 20-75 who were recruited to the Shanghai Breast Cancer Survival Study between 2002 and 2006 at approximately 6.5 months post-cancer diagnosis. Two cognitive assessments covering immediate memory, delayed memory, verbal fluency, and attention, were conducted at 18 and 36 months post-diagnosis. We used food frequency questionnaire to collect information on their dietary intake and supplement use between 18 and 36 months post-diagnosis. Linear regression models were used to examine the associations of dietary intake and supplement use with mean cognitive scores at 36 months post-diagnosis and with differences in cognitive scores between 18 and 36 months post-diagnosis. Higher vegetable, fruit and fish intake, supplementation with vitamin B and vitamin E, and tea drinking were associated with higher cognitive scores, while alcohol drinking was associated with lower cognitive scores at 36 months post-diagnosis. Vegetable intake was positively associated with improvement in verbal fluency, while tea drinking and fish oil supplementation were associated with greater improvements in delayed memory between 18 and 36 months post-diagnosis. Our results indicate that higher vegetable intake, tea drinking, and fish oil supplementation may help post-therapy cognitive recovery for cancer patients. Whole Grain Consumption and Breast Cancer: A Case-Control Study in Women JOURNAL OF THE AMERICAN COLLEGE OF NUTRITION English Article

breast cancer; whole grain consumption; dietary fiber consumption CARDIOVASCULAR-DISEASE; DIETARY FIBER; COLORECTAL-CANCER; RISK; METAANALYSIS; WEIGHT Objective: Whole grain consumption has long been associated with human health. However, its relationship with breast cancer remains not well understood and appreciated. The aim of this work was to evaluate the association between whole grain consumption and breast cancer in women. Methods: A case-control study was designed. Two hundred and fifty consecutive, newly diagnosed breast cancer female patients (56 +/- 12years) and 250 one-to-one age-matched controls were enrolled. A standardized, validated questionnaire assessing various sociodemographic, clinical, lifestyle, and dietary characteristics was applied through face-to-face interviews. Moreover, data on regular consumption of whole grains (i.e., never/rarely, 1-6times/week, >7times/week) were recorded. Overall dietary habits were assessed through the level of adherence to the Mediterranean diet using the MedDietScore (theoretical range 0-55). Results: Whole grain consumption of more than 7times/week was associated with a 0.49-fold (odds ratio = 0.49; 95% confidence interval, 0.29, 0.82) lower likelihood of having breast cancer, after adjustments were made. Conclusions: This study suggested that whole grain consumption more than 7times/week was consistently associated with reduced risk of breast cancer. J Kolar, M; Luksic, I; Gabrovec, B Kolar,
Marusa; Luksic, Igor; Gabrovec, Branko Public opinion
on the eligibility of health care for migrants and refugees in
Slovenia EASTERN MEDITERRANEAN HEALTH JOURNAL

English Article delivery
of health care; health care sectors; refugees; transients;
migrants CRISIS; EUROPE Background: Worldwide, more than 200
million people have left their home country, and international
migration from the Middle East to Europe is increasing. The
journey and the poor living conditions cause numerous health
problems. Migrants show significant differences in lifestyle,
health beliefs and risk factors compared with native populations
and this can impact access to health systems and participation in
prevention programmes. Aims: Our aim was to measure the attitude
of survey participants to migrants and to define up to what level
migrants are entitled to health care from the viewpoint of
Slovenian citizens. Methods: This survey was carried out in
January 2019 and included 311 respondents. We applied a
quantitative, nonexperimental sampling method. We used a
structured survey questionnaire based on an overview, a national
survey on the experiences of patients in hospitals and user
satisfaction with medical services of basic health care at the
primary level. Results: A large proportion of the respondents
agreed that migrants should receive emergency or full health care
provision, that there is no need to limit their health rights and
that they do not feel that their own rights are compromised by the
rights of migrants. Over 80% agreed with health protection for
women and for children. Conclusion: The findings offer a basis for
supplementing the existing, or designing a new, model of health
care provision for migrants in Slovenia, focusing on the provision
of health protection and care as a fundamental human right.

 Epidemiology of Breast Cancer in Women BREAST
 CANCER METASTASIS AND DRUG RESISTANCE: CHALLENGES AND PROGRESS,
 2ND EDITIONAdvances in Experimental Medicine and Biology
 English Article; Book Chapter
 Alcohol; Breast cancer; Diet; Epidemiology; Genetics;
 Physical activity DIETARY GLYCEMIC INDEX; BODY-MASS INDEX;
 RECREATIONAL PHYSICAL-ACTIVITY; POPULATION ATTRIBUTABLE RISK;
 POSTMENOPAUSAL HORMONE USE; GROWTH-FACTOR-I; MAMMOGRAPHIC DENSITY;
 AFRICAN-AMERICAN; MEDITERRANEAN DIET; LIFE-COURSE Epidemiologic
 studies have contributed importantly to current knowledge of
 environmental and genetic risk factors for breast cancer.
 Worldwide, breast cancer is an important cause of human suffering
 and premature mortality among women. In the United States, breast
 cancer accounts for more cancer deaths in women than any site
 other than lung cancer. A variety of risk factors for breast
 cancer have been well-established by epidemiologic studies
 including race, ethnicity, family history of cancer, and genetic
 traits, as well as modifiable exposures such as increased alcohol
 consumption, physical inactivity, exogenous hormones, and certain
 female reproductive factors. Younger age at menarche, parity, and
 older age at first full-term pregnancy may influence breast cancer
 risk through long-term effects on sex hormone levels or by other
 biological mechanisms. Recent studies have suggested that triple
 negative breast cancers may have a distinct etiology. Genetic
 variants and mutations in genes that code for proteins having a
 role in DNA repair pathways and the homologous recombination of
 DNA double stranded breaks (APEX1, BRCA1, BRCA2, XRCC2, XRCC3,
 ATM, CHEK2, PALB2, RAD51, XPD), have been implicated in some cases
 of breast cancer. [Coughlin, Steven S.] Augusta Univ, Med

 Food groups, diet quality and colorectal cancer

Colorectal cancer; Food group; Dietary quality; Mediterranean diet; Risk-factors; Case-control study
MEDITERRANEAN DIET; POOLED ANALYSIS; FATTY-ACIDS; PREVENTION; QUESTIONNAIRE; MECHANISMS; FREQUENCY; PATTERNS; DISEASE; FIBER BACKGROUND The results obtained to date concerning food groups, diet quality and colorectal cancer (CRC) risk vary according to criteria used and the study populations. AIM To study the relationships between food groups, diet quality and CRC risk, in an adult population of the Basque Country (North of Spain). METHODS This observational study included 308 patients diagnosed with CRC and 308 age- and sex-matched subjects as controls. During recruitment, dietary, anthropometric, lifestyle, socioeconomic, demographic and health status information was collected. Adherence to the dietary recommendations was evaluated utilizing the Healthy Eating Index for the Spanish Diet and the MedDietScore. Conditional logistic regressions were used to evaluate the associations of food group intakes, diet quality scores, categorized in tertiles, with CRC risk. RESULTS The adjusted models for potential confounding factors showed a direct association between milk and dairy products consumption, in particular high-fat cheeses [odds ratio (OR) third tertilevsfirst tertile = 1.87, 95% confidence intervals (CI): 1.11-3.16], and CRC risk. While the consumption of fiber-containing foods, especially whole grains (OR third tertilevsfirst tertile = 0.62, 95%CI: 0.39-0.98), and fatty fish (OR third tertilevsfirst tertile = 0.53, 95%CI: 0.27-0.99) was associated with a lower risk for CRC. Moreover, higher MD adherence was associated with a reduced CRC risk in adjusted models (OR third tertilevsfirst tertile = 0.40, 95%CI: 0.20-0.80). CONCLUSION Direct associations were found for high-fat cheese, whereas an inverse relation was reported for fiber-containing foods and fatty fish, as well as adherence to a Mediterranean dietary pattern. Breast Cancer in the Middle Eastern Population of
California, 1988-2004 BREAST JOURNAL English
Article breast cancer;

California; California Cancer Registry; Middle Eastern; salmon bias; survival MORTALITY; MIGRANTS This report presents the patterns of incidence, survival, and mortality of breast cancer in the Middle Eastern (ME) population of California. Cases were identified through surname recognition and population estimates were obtained from census public use files. Rates, trends, and survival in this ethnic group were compared with the non-Hispanic White (NHW) of California, as well as natives in the Middle East. Age-adjusted incidence rates for the insitu (22.8), invasive (126.2), and mortality (23.2) in ME women were significantly lower than similar rates of 26.0, 146.9, and 30.6 in the NHW women. Incidence rate in ME women in California was higher than rates in women in the Middle East. Lower rates for early stage and higher

rates for late stage diagnoses in this ethnic population suggest lack of optimal access to preventive healthcare. Relative survival in the two groups is negatively associated with stage at diagnosis and is slightly higher in ME women, probably due to large numbers of lost to follow-up in ME women suggesting the presence of salmon bias. Positive association with socioeconomic standing was detected only in the NHW women. Incidence of breast cancer in ME men was significantly higher than that of NHW men. Adherence to the Mediterranean Diet is Associated With Lower Likelihood of Breast Cancer: A Case-Control Study NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL

CARDIOVASCULAR-DISEASE; HEALTHY-ADULTS; OLIVE OIL; RISK; PATTERNS; ALCOHOL Mediterranean diet has long been associated with human health. However, its relationship with breast cancer remains not well understood and appreciated. The aim of this work was to evaluate the association between adherence to the Mediterranean diet and its inherent constituents, with breast-cancer. Two-hundred-and-fifty consecutive, newly diagnosed breast-cancer female patients (56 +/- 12 yr) and 250, 1-to-1 age-matched with the patients, controls, were studied. A standardized, validated questionnaire assessing various sociodemographic, clinical, lifestyle, and dietary characteristics, was applied through face-to-face interviews. Adherence to the Mediterranean diet was evaluated using the 11-components MedDietScore (theoretical range 0-55). Multiple logistic regression was applied to test the research hypothesis, whereas discriminant analysis was used to explore the strength of each component in relation to the outcome. One unit increase in the MedDietScore (i.e., greater adherence to the Mediterranean diet) was associated with 9% lower likelihood of having breast cancer (odds ratio = 0.91; 95% confidence interval, 0.86, 0.97). Decomposition of the MedDietScore revealed that the most important components and with beneficial effect were nonrefined cereals, vegetables, fruits, and alcohol, followed by red meat, but with unfavorable effect. A dietary recommendation for healthy eating, close to the Mediterranean dietary pattern, seems promising for breast cancer prevention.  Awareness of human papilloma virus and cervical
 cancer prevention among Cypriot female healthcare workers
 ECANCERMEDICALSCIENCE English Article

human papilloma virus; cervical cancer
 prevention; awareness; healthcare professionals; Cyprus HPV
 INFECTION; BEHAVIORS; KNOWLEDGE; VACCINES Background: Cervical
 cancer incidence varies around the world with the highest rates in
 Eastern Africa and the lowest rates in Western Asia. In Cyprus, a
 small Mediterranean island, cervical cancer incidence was 6.4 per
 100,000 in 2013. HPV is an established risk factor for cervical
 cancer with HPV-16 and HPV-18 being the most common carcinogenic
 strains. Cervical cancer is preventable through primary (HPV
 vaccination) and secondary (Pap and HPV tests) prevention. These
 prevention methods should be promoted, however, in order to design
 a cancer prevention programme and the awareness and
 characteristics of populations should be investigated so that
 prevention programmes can be targeted specifically to them.
 Methods: In this work, we sought to investigate awareness of HPV
 and cervical cancer prevention among female healthcare workers in
 Cyprus. To achieve this, we conducted a 60-item survey among 200
 healthcare professionals in randomly selected hospitals in two
 different cities within Cyprus. Results: Our results revealed that
 nearly 10% of our participants reported not ever having had a Pap
 test. 88.5% of the healthcare workers knew about HPV and 86.5%
 reported that HPV is transmitted through sexual intercourse. 83.5%
 of the participants were willing to vaccinate themselves for
 cervical cancer prevention. Conclusion: Even though awareness and
 vaccination acceptance were relatively high, they are still not
 optimal for healthcare professionals who play an essential role in
 health promotion. We suggest the design of educational programmes
 to target this population and improve their knowledge so that they
 can promote cervical cancer prevention in their health practice.

Mutations in p53, p53 protein overexpression and breast cancer survival JOURNAL OF CELLULAR AND MOLECULAR MEDICINE

English Article

breast cancer; p53 mutations; p53 overexpression; survival
CARCINOMA IN-SITU; PROGNOSTIC VALUE; GENE-MUTATIONS; RISK-FACTORS; IMMUNOHISTOCHEMICAL EXPRESSION; SURVEYOR(TM) NUCLEASE; MISSENSE MUTATIONS; TP53 MUTATION; MARKERS; GRADE p53 is an important tumour suppressor gene that encodes p53 protein, a molecule involved in cell cycle regulation and has been inconsistently linked to breast cancer survival. Using archived tumour tissue from a population-based sample of 859 women diagnosed with breast cancer between 1996 and 1997, we determined p53 mutations in exons 5-8 and p53 protein overexpression. We examined the association of p53 mutations with overexpression and selected tumour clinical parameters. We assessed whether either p53 marker was associated with survival through 2002, adjusting for other tumour markers and prognostic factors. The prevalence of protein overexpression in the tumour was 36% (307/859) and of any p53 mutation was 15% (128/859). p53 overexpression was positively associated with the presence of any p53 mutation (odds ratio [OR] = 2.2, 95% confidence interval [CI] = 1.5-3.2), particularly missense mutations (ER = 7.0, 95% CI = 3.6-13.7). Negative oestrogen and progesterone receptor (ER/PR) status was positively associated with both p53 protein overexpression (= 2.6, 95% CI = 1.7-4.0) and p53 mutation (OR = 3.9, 95% CI = 2.4-6.5). Any p53 mutation and missense mutations, but not p53 protein overexpression, were associated with breast cancer-specific mortality (hazard ratio [HR] = 1.7, 95% CI = 1.0-2.8; HR = 2.0, 95% CI = 1.1-3.6, respectively) and all-cause mortality (HR = 1.5, 95% CI = 1.0-2.4; HR = 2.0, 95% CI = 1.2-3.4, respectively); nonsense mutations were associated only with breast cancer-specific mortality (HR = 3.0, 95% CI = 1.1-8.1). These associations however did not remain after adjusting for ER/PR status. Thus, in this population-based cohort of women with breast cancer, although p53 protein overexpression and p53 mutations were associated with each other, neither independently impacted breast cancer-specific or all-causing mortality, after considering ER/PR status. Educational level and risk of colorectal cancer in EPIC with specific reference to tumor location INTERNATIONAL JOURNAL OF CANCER English Article

colorectal cancer; tumor location; educational level SOCIOECONOMIC-STATUS; UNITED-STATES; NUTRITION; COLON; SURVIVAL; HEALTH; WOMEN; INEQUALITIES; DEPRIVATION; RECTUM

Existing evidence is inconclusive on whether socioeconomic status (SES) and educational inequalities influence colorectal cancer (CRC) risk, and whether low or high SES/educational level is associated with developing CRC. The aim of our study was to investigate the relationship between educational level and CRC. We studied data from 400,510 participants in the EPIC (European Prospective Investigation into Cancer and Nutrition) study, of whom 2,447 developed CRC (colon: 1,551, rectum: 896, mean follow-up 8.3 years). Cox proportional hazard regression analysis stratified by age, gender and center, and adjusted for potential confounders were used to estimate hazard ratios (HR) and 95% confidence intervals (95% CI). Relative indices of inequality (RII) for education were estimated using Cox regression models. We conducted separate analyses for tumor location, gender and geographical region. Compared with participants with college/university education, participants with vocational secondary education or less had a nonsignificantly lower risk of developing CRC. When further stratified for tumor location, adjusted risk estimates for the proximal colon were statistically significant for primary education or less (HR 0.73, 95% CI 0.57-0.94) and for vocational secondary education (HR 0.76, 95% CI 0.58-0.98). The inverse association between low education and CRC risk was particularly found in women and Southern Europe. These associations were statistically significant for CRC, for colon cancer and for proximal colon cancer. In conclusion, CRC risk, especially in the proximal colon, is lower in subjects with a lower educational level compared to those with a higher educational level. This association is most pronounced in women and Southern Europe. [Leufkens, Anke M.; Siersema, Peter D.; Bueno-de-Mesquita, H. Holmes, MD Fung, Teresa T.; Chiuve, Stephanie E.;
Willett, Walter C.; Hankinson, Susan E.; Hu, Frank B.; Holmes,
Michelle D. Intake of specific fruits and vegetables in
relation to risk of estrogen receptor-negative breast cancer among
postmenopausal women BREAST CANCER RESEARCH AND TREATMENT
English Article

Breast cancer; Diet; Estrogen receptor; Incidence; Risk
PROSPECTIVE COHORT; POOLED ANALYSIS; CAROTENOIDS;
QUESTIONNAIRE; TOCOPHEROLS; VALIDATION; DISEASE; CELLS In
previous studies of postmenopausal women, overall intake of fruits
and vegetables groups has been inversely associated with estrogen
receptor-negative (ER-) breast cancer. In this analysis, we
prospectively examined the associations of specific fruits and
vegetables with risk of ER- postmenopausal breast cancer among
75,929 women aged 38-63 years at baseline and followed for up to
24 years. Dietary data were collected seven times during this
period. Cox proportional hazard models were used, adjusting for
potential confounders, including a modified Alternate
Mediterranean Diet score. We ascertained 792 incident cases of ER-
postmenopausal breast cancer. The multivariate relative risk (RR)
for every 2 servings/week consumption for total berries was 0.82
(95 % CI = 0.71-0.96, p = 0.01), and the RR for women who consumed
at least one serving of blueberries a week was 0.69 (95 % CI =
0.50-0.95, p = 0.02) compared with non-consumers. Also, the RR for
consuming at least 2 servings of peaches/nectarines per week was
0.59 (95 % CI = 0.37-0.93, p = 0.02). Risk of ER- breast cancer
was not associated with intakes of other specific fruits or
vegetables. In conclusion, higher intake of berries and peaches
was associated with lower risk of ER- breast cancer among
postmenopausal women. These results are considered exploratory and
need to be confirmed in further studies. [Fung, Teresa T.]

breast cancer; glycemic index; glycemic load; mediterranean diet; postmenopausal DENSITY-LIPOPROTEIN CHOLESTEROL; PHYSICAL-ACTIVITY QUESTIONNAIRE; FOOD-FREQUENCY QUESTIONNAIRE; MEDITERRANEAN DIET; CARBOHYDRATE INTAKE; DIABETES-MELLITUS; RISK; FIBER; METAANALYSIS; VALIDATION The objective of this study was to evaluate the prospective associations between dietary glycemic index (GI) and glycemic load (GL) and the risk for invasive breast cancer incidence in postmenopausal women at

high cardiovascular disease (CVD) risk. This study was conducted within the framework of the PREvencion con DIeta MEDiterranea (PREDIMED) study, a nutritional intervention trial for primary cardiovascular prevention. We included 4010 women aged between 60 and 80 years who were initially free from breast cancer but at high risk for CVD disease. Dietary information was collected using a validated 137-item food frequency questionnaire. We assigned GI values using the International Tables of GI and GL values. Cases were ascertained through yearly consultation of medical records and through consultation of the National Death Index. Only cases confirmed by results from cytology tests or histological evaluation were included. We estimated multivariable-adjusted hazard ratios for invasive breast cancer risk across tertiles of energy-adjusted dietary GI/GL using Cox regression models. We repeated our analyses using yearly repeated measures of GI/GL intakes. No associations were found between baseline dietary GI/GL and invasive breast cancer incidence. The multivariable hazard ratio and 95% confidence interval (CI) for the top tertile of dietary GI was 1.02 (95% CI: 0.42-2.46) and for dietary GL was 1.00 (95% CI: 0.44-2.30) when compared with the bottom tertile. Repeated-measures analyses yielded similar results. In sensitivity analyses, no significant associations were observed for women with obesity or diabetes. Dietary GI and GL did not appear to be associated with an increased risk for invasive breast cancer in postmenopausal women at high CVD risk. Ethnic Wage Penalty and Human Capital
Transferability: A Comparative Study of Recent Migrants in 11
European Countries INTERNATIONAL MIGRATION REVIEW
English Article ethnic
penalty; labor market; Europe LABOR-MARKET; OCCUPATIONAL
INTEGRATION; NONWESTERN IMMIGRANTS; SAMPLE SELECTION; CLASS
ATTAINMENT; SOCIAL-MOBILITY; EDUCATION; EARNINGS; UNEMPLOYMENT;
ASSIMILATION This article examines the ethnic wage penalty
among migrants in 11 Western European countries. It aims to extend
the literature on the models of migrant occupational inclusion in
European labor markets by studying the wage gap and to disentangle
whether the gross wage penalty experienced by foreign-born
residents can be explained by human capital-related factors and/or
by migrants' occupational segregation. Estimating probit models
with sample selection on European Labour Force Survey data (2009-
2016), we find that both male and female migrants experienced a
larger gross wage penalty in Southern Europe, where they had lower
education levels and faced stronger occupational segregation. In
the other countries under study, we find a smaller gross wage
penalty among foreign-born women. Results show that migrants from
Eastern Europe were not systematically less penalized than
migrants from Africa, Asia, and Latin America, except for men in
Italy and Greece. Wage penalties were higher among tertiary-
educated migrants, compared to their less-educated counterparts,
only in Mediterranean countries, where the former were mainly
concentrated at the bottom of the occupational structure. Finally,
the acquisition of the highest education after migration reduced
migrants' wage penalty, thanks to a better match between
educational credentials and job allocation, especially in Southern
Europe. Focusing on the ethnic wage penalty and on both human
capital- and occupation-related factors of ethnic penalization
highlights cross-country differences not yet explored by existing
comparative research, allowing a new and more comprehensive
picture of migrants' penalization in Europe. [Cantalini, Stefano]

Female genital mutilation and noninvasive cervical abnormalities and invasive cervical cancer in Senegal, West Africa: A retrospective study INTERNATIONAL JOURNAL OF CANCER
English Article

cervical cancer; female genital mutilation; sub-Saharan Africa; Senegal HUMAN-PAPILLOMAVIRUS INFECTION; RISK; INFLAMMATION; COFACTORS; ETIOLOGY; WOMEN Female genital mutilation or cutting (FGM/C) is a traditional practice that affects a significant portion of women in sub-Saharan Africa, Egypt, areas of the Middle East and some countries in Asia. While clinical and epidemiological studies have established a close association between inflammation and carcinogenesis, particularly in epithelial cancers, the relationship between FGM/C and cervical cancer is not well known. We performed a secondary analysis using combined data from six research studies conducted in and around Dakar, Senegal from 1994 to 2012. Study subjects included both asymptomatic women who presented to outpatient clinics but were screened for cervical cancer, and women with cancer symptoms who were referred for cervical cancer treatment. We used unconditional logistic regression to estimate adjusted pooled odds ratios (ORs) and 95% confidence intervals (CI) for associations between FGM/C and (1) Invasive cervical cancer (ICC) and (2) noninvasive cervical abnormalities. After adjusting for confounding, women with ICC were 2.50 times more likely to have undergone FGM/C than women without cervical abnormalities (95% CI, 1.28-4.91). Restricting to HPV-positive women increased the strength of the association (OR = 4.23; 95% CI 1.73-10.32). No significant associations between FGM/C and noninvasive cervical abnormalities were observed, except in commercial sex workers with FGM/C (OR = 2.01; 95% CI 1.19-3.40). The potential increased risk for ICC suggested by our study warrants further examination. Study results may impact cancer prevention efforts in populations where FGM/C is practiced and draw awareness to the additional health risks associated with FGM/C. J Crujeiras, AB; Cueva, J; Vieito, M; Curiel, T; López-López, R; Pollán, M; Casanueva, FF Crujeiras, A. B.; Cueva, J.; Vieito, M.; Curiel, T.; Lopez-Lopez, R.; Pollan, M.; Casanueva, F. F. Association of breast cancer and obesity in a homogeneous population from Spain JOURNAL OF ENDOCRINOLOGICAL INVESTIGATION English Article

Adipokines; breast cancer incidence; dietary patterns; obesity OVERWEIGHT; DIET; WEIGHT; FOOD; COHORT; WOMEN; RISK; SIZE Objective: To evaluate for the first time in Spain if the association between obesity and breast cancer prognosis is similar to that reported in other countries with non Mediterranean dietary patterns. Methods: Weight and height and other variables of interest, tumor characteristics and current clinical status 3 yr after diagnosis were retrieved from medical files of breast cancer women diagnosed during 2006. A total of 159 cases with complete information were studied and categorized according to the World Health Organization criteria in normal-/under-weight, overweight, and obese. Results: Among breast cancer patients, 70.4% were classified as overweight/obese and 29.6% as normal weight. Prevalence of obesity was high (38.4%) in comparison with information reported for healthy women of the same

region (27.11%) and was higher among post-menopausal patients and in women with low level of alcohol and tobacco consumption. Moreover, overweight/obese cases (79.5%) tended to have more often human epidermal growth factor receptor 2 status negative when compared with those with normal weight (70.2%; $p=0.097$) and the survival curves tended to be influenced by body mass index although without statistical significance. Conclusions: Overweight/obesity in a Mediterranean country is highly prevalent among breast cancer patients. Our results support a putative influence of obesity per se and not the alimentary patterns as a prognostic factor in breast cancer patients justifying the need to perform larger prospective studies. J Al-Kuraya, K; Siraj, AK; Bavi, P; Al-Jommah, N; Ezzat, A; Sheikh, S; Amr, S; Al-Dayel, F; Simon, R; Guido, S

Al-Kuraya, K; Siraj, AK; Bavi, P; Al-Jommah, N; Ezzat, A; Sheikh, S; Amr, S; Al-Dayel, F; Simon, R; Guido, S High epidermal growth factor receptor amplification rate but low mutation frequency in Middle East lung cancer population HUMAN

PATHOLOGY

English Article

EGFR; epidermal growth factor receptor; mutation; amplification; gefitinib; Middle East; lung cancer GENE AMPLIFICATION; BREAST-CANCER; TISSUE MICROARRAYS; PROTEIN EXPRESSION; EGFR INHIBITORS; GEFITINIB; OVEREXPRESSION; CARCINOMAS; IMPACT Epidermal growth factor receptor (EGFR) exon 18-21 mutations were shown to be highly predictive of response to gefitinib (Iressa) therapy in lung cancer. Studies on Western and Japanese lung cancers have indicated substantial differences in the EGFR mutation frequency between these populations. To investigate the prevalence of EGFR in another distinct ethnic group, EGFR alterations were studied in 47 consecutive non small cell lung cancers from Saudi Arabia by immunohistochemistry, fluorescence in situ hybridization, and DNA sequencing. Detectable EGFR expression was seen in 69.8% of 43 interpretable cancers. Epidermal growth factor receptor amplification, present in 15.3% of 39 analyzable cancers, was strongly associated with high levels of EGFR expression ($P = .0047$). Only 1 exon 18-21 mutation was seen among 34 lung cancers that could be successfully sequenced. It is concluded that EGFR exon 18-21 mutations are rare in Middle East patients with lung cancer and occur in a similar range as in Western patients. The remarkable high rate of EGFR gene amplifications could potentially facilitate studies on the predictive role of gene copy number changes for response to anti-EGFR therapies in Middle East patient sets. IGF-I; RISKWestern lifestyle, characterized by reduced physical activity and a diet rich in fat, refined carbohydrates, and animal protein is associated with high prevalence of overweight, metabolic syndrome, insulin resistance, and high plasma levels of several growth factors and sex hormones. Most of these factors are associated with breast cancer risk and, in breast cancer patients, with increased risk of recurrences. Recent trials have proven that such a metabolic and endocrine imbalance can be favorably modified through comprehensive dietary modification, shifting from Western to Mediterranean and macrobiotic diet. J Bozorgi, A; Khazaei, F; Bozorgi, M; Khazaei, M
Bozorgi, Azam; Khazaei, Fatemeh; Bozorgi, Maryam; Khazaei, Mozafar In Vitro Stem Cell Isolation from Human Breast Cancer MIDDLE EAST JOURNAL OF CANCER English Article Breast cancer; Cancer stem cells; Isolation PROSPECTIVE IDENTIFICATION; TUMOR; ANTIGENS; SOX2; IRAN Background: Breast cancer (BC) is the most prevalent cancer among women worldwide with significant incidence and death rates. Nowadays, researchers hold that tumor formation, failure in therapy, and disease progression are all related to the presence of a small fraction of cancer cells with self-renewal capability known as "breast cancer stem cells" (BCSCs). Therefore, the study of this cancer cell population can be conducive to eradicating the tumor. The objective of the present study was to survey the existence and in vitro isolation of human BCSCs. Method: An in vitro research study was conducted under controlled laboratory settings to isolate, enrich, and identify breast cancer stem cells. Briefly, fresh breast tumors were carried to the lab immediately after surgery, followed by mechanical and enzymatic digestion (2 mg/ml collagenase I). Then, digested samples were passed through cell strainers (70 and 40 μ m), and obtained cell suspension was cultured under the serum-free medium supplemented with growth factors for 21 days. The expression of cluster of differentiation 44 (CD44) and cluster of differentiation 24 (CD24) surface markers was assessed using immunocytochemistry, and stem cell gene expression was analyzed via RT-PCR. Results: BCSCs were able to survive in serum-free conditions and form floating spheres in vitro. Cells obtained from mammospheres expressed CD44 as the

membranous and cytoplasmic pattern while CD24 expression was negative. Also, octamer-binding transcription factor 4 and SOX2 gene expression was observed in BCSCs. Conclusion: The presence of stem cells was confirmed in Iranian women BC, and an efficient in vitro mammosphere culture model was used to enrich and propagate BCSCs. In our opinion, this in vitro model could be a suitable method for isolating and enriching BCSCs. J Akin, H; Tözün, N Akin, Hakan; Tozun, Nurdan Diet, Microbiota, and Colorectal Cancer

JOURNAL OF CLINICAL GASTROENTEROLOGY English

Article colorectal cancer;

microbiota; diet; dysbiosis; probiotics GUT MICROBIOTA; INTESTINAL MICROBIOTA; MEDITERRANEAN DIET; PREVENTION; METABOLITES; MICROFLORA; PROBIOTICS; CULTURE; DISEASE; HEALTH Colorectal cancer (CRC) is the third most common cancer in the world causing nearly 500,000 deaths every year. In addition to genetic background, environmental factors including diet and lifestyle are accepted as major contributors to adenoma and CRC development. Lifestyle factors include high BMI, obesity, and reduced physical activity. Growing interest and accumulating data on human microbiota implicate that host-microbe interplay has an important role in the development of metabolic, neoplastic, and inflammatory diseases. Findings from recent studies suggest that colon cancer risk is determined by the interaction between diet and gut microbiota. Dietary changes affect gut microbiota and conversely microbiota mediates the generation of dietary factors triggering colon cancer. Identification of the microbial communities associated with carcinogenesis is of crucial importance. Nowadays, with the evolvement of culture-independent molecular techniques, it has become possible to identify main bacterial species in healthy individuals, inflammatory conditions, and CRC. Some recent studies have shown the differences in intestinal microbiota between colon cancer patients and healthy individuals. Animal studies have provided a better understanding of interaction between pathobionts and symbionts in the development of colon cancer. There is no single causative organism identified in CRC; however, there is strong evidence that reduction of protective bacteria, increase in some bacteria (ie, fusobacterium members;

Bacteroides/Prevotella), and age-related changes in microbiota have an impact on adenoma or cancer development. Future studies will enable us to understand procarcinogenic and anticarcinogenic mechanisms and give insights to rational manipulation of the microbiota with prebiotics, probiotics, or dietary modifications.

Metastasis in the MMTV-PyMT Mouse Model of Breast Cancer NUTRIENTS
English Article

diet; fatty acid; breast cancer; lung metastasis MAMMARY
TUMORIGENESIS; MEDITERRANEAN DIET; RISK; ACIDS; OBESITY; HEALTH;
ALPHA; WOMEN; ASSOCIATION; PATTERNS A high-fat diet (HFD) and
obesity are risk factors for many diseases including breast
cancer. This is particularly important with close to 40% of the
current adult population being overweight or obese. Previous
studies have implicated that Mediterranean diets (MDs) partially
protect against breast cancer. However, to date, the links between
diet and breast cancer progression are not well defined.
Therefore, to begin to define and assess this, we used an
isocaloric control diet (CD) and two HFDs enriched with either
olive oil (OObD, high in oleate, and unsaturated fatty acid in
MDs) or a milk fat-based diet (MFBD, high in palmitate and
myristate, saturated fatty acids in Western diets) in a mammary
polyomavirus middle T antigen mouse model (MMTV-PyMT) of breast
cancer. Our data demonstrate that neither MFBD or OObD altered the
growth of primary tumors in the MMTV-PyMT mice. The examination of
lung metastases revealed that OObD mice exhibited fewer surface
nodules and smaller metastases when compared to MFBD and CD mice.
These data suggest that different fatty acids found in different
sources of HFDs may alter breast cancer metastasis.

Cancer health disparities;
Colorectal cancer; Mediterranean diet; Weight loss; Gut microbiome; Bile acids; Nutrition GENE-EXPRESSION PROFILES; US ADULTS; QUALITY; COLONOCYTES; COMBINATION; METABOLISM; BIOMARKERS;

FREQUENCY; SURGERY; PROTEIN Background Among all racial/ethnic groups, people who identify as African American/Blacks have the second highest colorectal cancer (CRC) incidence in the USA. This disparity may exist because African American/Blacks, compared to other racial/ethnic groups, have a higher prevalence of risk factors for CRC, including obesity, low fiber consumption, and higher intakes of fat and animal protein. One unexplored, underlying mechanism of this relationship is the bile acid-gut microbiome axis. High saturated fat, low fiber diets, and obesity lead to increases in tumor promoting secondary bile acids. Diets high in fiber, such as a Mediterranean diet, and intentional weight loss may reduce CRC risk by modulating the bile acid-gut microbiome axis. The purpose of this study is to test the impact of a Mediterranean diet alone, weight loss alone, or both, compared to typical diet controls on the bile acid-gut microbiome axis and CRC risk factors among African American/Blacks with obesity. Because weight loss or a Mediterranean diet alone can reduce CRC risk, we hypothesize that weight loss plus a Mediterranean diet will reduce CRC risk the most. Methods This randomized controlled lifestyle intervention will randomize 192 African American/Blacks with obesity, aged 45-75 years to one of four arms: Mediterranean diet, weight loss, weight loss plus Mediterranean diet, or typical diet controls, for 6 months (48 per arm). Data will be collected at baseline, mid-study, and study end. Primary outcomes include total circulating and fecal bile acids, taurine-conjugated bile acids, and deoxycholic acid. Secondary outcomes include body weight, body composition, dietary change, physical activity, metabolic risk, circulating cytokines, gut microbial community structure and composition, fecal short-chain fatty acids, and expression levels of genes from exfoliated intestinal cells linked to carcinogenesis. Discussion This study will be the first randomized controlled trial to examine the effects of a Mediterranean diet, weight loss, or both on bile acid metabolism, the gut microbiome, and intestinal epithelial genes associated with carcinogenesis. This approach to CRC risk reduction may be especially important among African American/Blacks given their higher risk factor profile and increased CRC incidence. breaks OVARIAN-CANCER; MAINTENANCE; GERMLINE; MUTATION; BREAST; OLAPARIB; THERAPY BACKGROUND Poly (ADP-ribose) polymerase inhibitors (PARPis) are approved as first-line therapies for breast cancer gene (BRCA)-positive, human epidermal growth factor receptor 2-negative locally advanced or metastatic breast cancer. They are also effective for new and recurrent ovarian cancers that are BRCA- or homologous recombination deficiency (HRD)-positive. However, data on these mutations and PARPi use in the Middle East are limited. AIM To assess BRCA/HRD prevalence and PARPi use in patients in the Middle East with breast/ovarian cancer. METHODS This was a single-center retrospective study of 57 of 472 breast cancer patients tested for BRCA mutations, and 25 of 65 ovarian cancer patients tested for HRD. These adult patients participated in at least four visits to the oncology service at our center between August 2021 and May 2023. Data were summarized using descriptive statistics and compared using counts and percentages. Response to treatment was assessed using Response Evaluation Criteria in Solid Tumors criteria. RESULTS Among the 472 breast cancer patients, 12.1% underwent BRCA testing, and 38.5% of 65 ovarian cancer patients received HRD testing. Pathogenic mutations were found in 25.6% of the tested patients: 26.3% breast cancers had germline BRCA (gBRCA) mutations and 24.0% ovarian cancers showed HRD. Notably, 40.0% of gBRCA-positive breast cancers and 66.0% of HRD-positive ovarian cancers were Middle Eastern and Asian patients, respectively. PARPi treatment was used in 5 (33.3%) gBRCA-positive breast cancer patients as first-line therapy (n = 1; 7-months progression-free), for maintenance (n = 2; > 15-months progression-free), or at later stages due to compliance issues (n = 2). Four patients (66.6%) with HRD-positive ovarian cancer received PARPi and all remained progression-free. CONCLUSION Lower testing rates but higher BRCA mutations in breast cancer were found. Ethnicity reflected United Arab Emirates demographics, with breast cancer in Middle Eastern and ovarian cancer in Asian patients. J Aragón, F; Perdigón, G; de LeBlanc, AD

Aragón, Felix; Perdigón, Gabriela; de Moreno de LeBlanc,

Alejandra Modification in the diet can induce
beneficial effects against breast cancer WORLD JOURNAL OF
CLINICAL ONCOLOGY English Article

Breast cancer; Nutrition; Probiotic;
Fermented products The population tends to consume foods
that in addition to their nutritional values can offer some
benefits to their health. There are many epidemiological evidences
and research studies in animal models suggesting that diet plays
an important role in breast cancer prevention or progression. This
review summarized some of the relevant researches about nutrition
and cancer during the last years, especially in breast cancer. The
analysis of probiotics and fermented products containing lactic
acid bacteria in cancer prevention and/or treatment was especially
discussed. It was observed that a balance of fatty acids similar
to those of traditional Mediterranean diet, the consumption of
fruits and vegetables, dietary fiber intake, vitamin
supplementation are, along with the intake of probiotic products,
the most extensively studied by the negative association to breast
cancer risk. The consumption of probiotics and fermented products
containing lactic acid bacteria was associated to reduce breast
cancer risk in some epidemiological studies. The use of animal
models showed the modulation of the host's immune response as one
of the important effects associated to the benefices observed with
most probiotics. However; future assays in human are very
important before the medical community can accept the addition of
probiotic or fermented milks containing lactic acid bacteria as
supplements for cancer patients. (C) 2014 Baishideng Publishing

BREAST CANCER RESEARCH AND TREATMENT English Article

Breast cancer; Vegetables; Fruit; Longitudinal study; Risk FOOD GROUPS; DIET; METAANALYSIS; WOMEN; MICRONUTRIENTS; PROJECT; DESIGN; COHORT The role of fruit and vegetables in breast cancer (BC) development has long been debated. A large variety of vegetables and fruit are consumed by Mediterranean populations, a favourable setting for evaluating the effects of these foods. The association between vegetables and fruit consumption, overall and by specific types, and BC risk was studied in the Italian section of the European Prospective Investigation into Cancer and Nutrition study. Over 31,000 women, aged 36-64 years, recruited in five Italian centers between 1993 and 1998, were available for analyses with dietary and lifestyle information and anthropometric measurements. After a median follow-up of 11.25 years, 1,072 invasive and in situ incident BC cases were identified. Cox proportional hazard models (adjusted for education, anthropometry, reproductive history, hormone replacement therapy, physical activity, alcohol consumption and smoking habits) showed an inverse association between consumption of all vegetables and BC risk (highest vs. lowest quintile HR 0.65; 95% CI 0.53-0.81, P for trend = 0.003). According to subtypes of vegetables, an inverse association emerged for increasing consumption of leafy vegetables (highest vs. lowest quintile HR 0.70; 95% CI 0.57-0.86, P for trend = 0.0001) and fruiting vegetables (highest vs. lowest quintile HR 0.75; 95% CI 0.60-0.94, P for trend = 0.01). An inverse association also emerged with increasing consumption of raw tomatoes (P for trend = 0.03). In contrast, no association of fruit, overall or by subtypes, with BC risk was found. In this Mediterranean population, a clear protective role of increasing vegetables consumption, mainly leafy and fruiting vegetables, on BC risk emerged. Molecular markers and pathway analysis of colorectal carcinoma in the Middle East

CANCER English Article alternate pathway; colorectal cancer; Middle East; molecular pathways; serrated pathway; traditional pathway ISLAND METHYLATOR PHENOTYPE; BRAF MUTATIONS; MICROSATELLITE INSTABILITY; SERRATED PATHWAY; MEAT CONSUMPTION; CANCER; PATTERNS; AGE; ASSOCIATIONS; METAANALYSIS BACKGROUND Colorectal cancer (CRC) is one of the most common cancers in the world. A newly proposed integrated pathway comprising traditional, alternate, and serrated pathways by genetic and epigenetic factors was defined recently and hypothesized to play a role in the pathogenesis of CRC; however, to the authors' knowledge, there is a paucity of information regarding these proposed molecular pathways in different ethnic groups. METHODS Molecular characterization of 770 CRC specimens was performed for microsatellite instability, BRAF, and KRAS by polymerase chain reaction and 500 cases for CpG island methylator phenotype (CIMP) high phenotype by MethyLight technology. Tumors were assigned to different molecular pathways and examined for clinicopathological correlation and survival analysis. RESULTS The traditional pathway constituted 33.4% of CRC cases, the alternate

pathway comprised 11.6%, and the serrated molecular pathway accounted for only 0.8% of Middle Eastern CRC cases. Approximately 54.2% of CRC cases did not qualify to fit into any pathway and thus were designated as an unassigned group. Molecular pathways were found to be significantly associated with tumor site and grade. A subset of cases with an uncategorized pathway demonstrated a significant survival difference ($P = .0079$).

CONCLUSIONS The serrated pathway was found to account for a very low percentage of the CRC patient cohort in the current study. The unassigned group accounted for the majority of Middle Eastern CRC cases, and therefore methods of CRC pathway analysis might not be applicable to this ethnic group. The current study demonstrates the need to unravel the molecular genetic basis of this disease to further subcategorize these CRC cases. It also identifies a need for further studies on different populations for a better understanding of their exact role and incidence. Cancer 2015;121:3799-3808. (c) 2015 American Cancer Society. The results of the current study indicate the need to unravel the molecular genetic basis of colorectal carcinoma to further subcategorize colorectal carcinoma cases. They also emphasize the need to perform further studies on different populations to develop a better understanding of the exact role and incidence of genetic pathways. food groups; diet; meta-analysis; dose-response; colorectal cancer DOSE-RESPONSE METAANALYSIS; MEDITERRANEAN DIET; TREND ESTIMATION; CALCIUM; COLON; MECHANISMS; MICROBIOTA; MORTALITY; ADHERENCE; PATTERNS The aim of this systematic review and meta-analysis was to summarize the evidence on the relationship between intake of 12 major food groups, including whole grains, refined grains, vegetables, fruit, nuts, legumes, eggs, dairy, fish, red meat, processed meat and sugar-sweetened beverages with risk of colorectal cancer (CRC). We conducted a systematic search in PubMed and Embase for prospective studies investigating the association between these 12 food groups and risk of CRC until April 2017. Summary risk ratios (RRs) and 95% confidence intervals (95% CI) were estimated using a random effects model for high vs. low intake categories, as well as for linear and nonlinear relationships. An inverse association was observed for whole grains (RR30g/d: 0.95, 95% CI 0.93, 0.97; n=9 studies), vegetables (RR100g/d: 0.97, 95% CI 0.96, 0.98; n=15), fruit (RR100g/d: 0.97, 95% CI 0.95, 0.99; n=16) and dairy (RR200g/d: 0.93, 95% CI 0.91, 0.94; n=15), while a positive association for red meat (RR100g/d: 1.12, 95% CI 1.06, 1.19; n=21) and processed meat (RR50g/d: 1.17, 95% CI 1.10, 1.23; n=16), was seen in the linear dose-response meta-analysis. Some evidence for nonlinear relationships was observed between vegetables, fruit and dairy and risk of colorectal cancer. Findings of this meta-analysis showed that a diet characterized by high intake of whole grains, vegetables, fruit and dairy products and low amounts of red meat and processed meat was associated with lower risk of CRC.

 Targeting cancer-cell mitochondria using Tigecycline
 improves radiotherapy response in colorectal cancer cell line
 MUTATION RESEARCH-FUNDAMENTAL AND MOLECULAR MECHANISMS OF
 MUTAGENESIS English Article
 Colorectal cancer; Tigecycline; Radiotherapy;
 Apoptosis RADIATION-THERAPY; INHIBITION; CARCINOMA; RESISTANT
 Background: Colorectal cancer (CRC) is the third most common
 cancer worldwide and causes more than 50,000 deaths in the United
 States each year. Due to the limited therapeutic options and poor
 prognosis in CRC, extensive research and development of novel
 therapeutic methods is essential. In this regard, the presence of
 cancer stem cells with unlimited division ability is the main
 reason for the therapeutic resistance in CRC. Tigecycline is a
 pharmacological mitochondria inhibitor and blocks mitochondria-
 related cell proliferation in cancer cells. This study
 investigated the effects of Tigecycline combined with radiotherapy
 on CRC cell apoptosis. Methods: Human colorectal cancer cells
 (HCT-116) were treated with Tigecycline, and cell viability was
 measured with MTT assay. In the next step, the cells were exposed
 to radiation using a Siemens Primus 6 MV linear accelerator at
 radiation dose of 400 cGy. Finally, we evaluated cancer cell
 apoptosis, caspase-3 activity and apoptotic-related genes
 expression with AnnexinV/PI, flowcytometry and gene expression,
 respectively. Results: The MTT assay revealed an IC50 value of 93
 μ M for Tigecycline after 48 hours. Mitochondria inhibition, at
 its IC50 value, sensitizes colorectal cancer cells to
 radiotherapy. Compared to monotherapy, the combination therapy
 increased the number of apoptotic cells and caspase-3 activity,
 up-regulated pro-apoptotic genes, and down-regulated anti-
 apoptotic genes. Conclusion: In conclusion, our data suggests that
 targeting mitochondria may represent a clinically relevant
 approach to enhance the sensitivity of colorectal cancer cells to
 therapy. These findings could provide new insights into cancer
 therapy and might be used as a novel method to improve the current
 state of CRC therapy. [Khodaei, Sepideh Hassanpour] Eastern

Mediterranean Diet and Invasive Breast Cancer Risk
Among Women at High Cardiovascular Risk in the PREDIMED Trial A
Randomized Clinical Trial JAMA INTERNAL MEDICINE
English Article

PHYSICAL-ACTIVITY QUESTIONNAIRE; OXIDATIVE DNA-DAMAGE; OLIVE OIL INTAKE; FAT; ADHERENCE; PATTERN; HEALTH; METAANALYSIS; VALIDATION; MORTALITY IMPORTANCE Breast cancer is the leading cause of female cancer burden, and its incidence has increased by more than 20% worldwide since 2008. Some observational studies have suggested that the Mediterranean diet may reduce the risk of breast cancer. OBJECTIVE To evaluate the effect of 2 interventions with Mediterranean diet vs the advice to follow a low-fat diet (control) on breast cancer incidence. DESIGN, SETTING, AND PARTICIPANTS The PREDIMED study is a 1:1:1 randomized, single-blind, controlled field trial conducted at primary health care centers in Spain. From 2003 to 2009, 4282 women aged 60 to 80 years and at high cardiovascular disease risk were recruited after invitation by their primary care physicians. INTERVENTIONS Participants were randomly allocated to a Mediterranean diet supplemented with extra-virgin olive oil, a Mediterranean diet supplemented with mixed nuts, or a control diet (advice to reduce dietary fat). MAIN OUTCOMES AND MEASURES Breast cancer incidence was a prespecified secondary outcome of the trial for women without a prior history of breast cancer (n = 4152). RESULTS After a median follow-up of 4.8 years, we identified 35 confirmed incident cases of breast cancer. Observed rates (per 1000 person-years) were 1.1 for the Mediterranean diet with extra-virgin olive oil group, 1.8 for the Mediterranean diet with nuts group, and 2.9 for the control group. The multivariable-adjusted hazard ratios vs the control group were 0.32 (95% CI, 0.13-0.79) for the Mediterranean diet with extra-virgin olive oil group and 0.59 (95% CI, 0.26-1.35) for the Mediterranean diet with nuts group. In analyses with yearly cumulative updated dietary exposures, the

hazard ratio for each additional 5% of calories from extra-virgin olive oil was 0.72 (95% CI, 0.57-0.90). CONCLUSIONS AND RELEVANCE This is the first randomized trial finding an effect of a long-term dietary intervention on breast cancer incidence. Our results suggest a beneficial effect of a Mediterranean diet supplemented with extra-virgin olive oil in the primary prevention of breast cancer. These results come from a secondary analysis of a previous trial and are based on few incident cases and, therefore, need to be confirmed in longer-term and larger studies. Effects of Cynara Cardunculus in Colorectal Cancer Cells Are
Modulated by the Circadian Clock INTERNATIONAL JOURNAL OF
MOLECULAR SCIENCES English Article
circadian clock; colorectal cancer; plant-
derived compounds; proliferation; treatment sensitivity;
apoptosis; cytotoxicity GENE; CYNAROPICRIN; SENSITIVITY;
EXPRESSION; HALLMARKS; PLANTS; MACC1 The circadian clock
generates 24 h rhythms in behavioural, cellular and molecular
processes. Malfunctions of the clock are associated with enhanced
susceptibility to cancer, worse treatment response and poor
prognosis. Clock-controlled genes are involved in cellular
processes associated with tumour development and progression
including metabolism of drugs and the cell cycle. Cynara
cardunculus, a plant of the Asteraceae family, has been reported
to have antiproliferative effects on breast cancer cells. Here, we
used the human colorectal cancer (CRC) cell line HCT116 and its
knockout variants for different core-clock genes (BMAL1, PER2,
NR1D1), to investigate the treatment effect of C. cardunculus
lipophilic leaf extract under different clock scenarios. Our
results show a direct effect of C. cardunculus on the circadian
phenotype of the cells, as indicated by alterations in the phase,
amplitude, and period length of core-clock gene oscillations.
Furthermore, our data indicate a role for the circadian clock in
sensitivity to C. cardunculus treatment. In particular, the
treatment inhibited proliferation and induced cytotoxicity and
apoptosis in a clock knockout-specific manner, in CRC cells. These
results point to a potential effect of C. cardunculus lipophilic
leaf extracts as a modulator of the circadian clock, in addition
to its anti-proliferative properties. [Fuhr, Luise; Basti,

Overview on health research ethics in Egypt and North Africa EUROPEAN JOURNAL OF PUBLIC HEALTH English Article EASTERN MEDITERRANEAN REGION; COMMITTEES Developing countries, including Egypt and North African countries, need to improve their quality of research by enhancing international cooperation and exchanges of scientific information, as well as competing for obtaining

international funds to support research activities. Research must comply with laws and other requirements for research that involves human subjects. The purpose of this article is to overview the status of health research ethics in Egypt and North African countries, with reference to other Middle Eastern countries. The EU and North African Migrants: Health and Health Systems project (EUNAM) has supported the revision of the status of health research ethics in Egypt and North African countries, by holding meetings and discussions to collect information about research ethics committees in Egypt, and revising the structure and guidelines of the committees, as well as reviewing the literature concerning ethics activities in the concerned countries. This overview has revealed that noticeable efforts have been made to regulate research ethics in certain countries in the Middle East. This can be seen in the new regulations, which contain the majority of protections mentioned in the international guidelines related to research ethics. For most of the internationally registered research ethics committees in North African countries, the composition and functionality reflect the international guidelines. There is growing awareness of research ethics in these countries, which extends to teaching efforts to undergraduate and postgraduate medical students. J Farazi, PA; Hadji, P; Roupa, Z Farazi, Paraskevi A.; Hadji, Panayiota; Roupa, Zoe Awareness of human papilloma virus and cervical cancer prevention among Greek female healthcare workers EUROPEAN JOURNAL OF CANCER PREVENTION English Article

awareness; cervical cancer; healthcare workers; human papilloma virus; prevention HPV INFECTION; RISK-FACTORS; SUSTAINED EFFICACY; PARTICLE VACCINE; CONTROLLED-TRIAL; SQUAMOUS-CELL; YOUNG-WOMEN; METAANALYSIS; DISEASES; KNOWLEDGE The incidence rate of cervical cancer varies by geographic region, with less developed regions showing the highest rates. All risk factors for cervical cancer are actually preventable if appropriate lifestyle changes are adopted. In addition, vaccines protecting against the majority of human papilloma virus (HPV) high-risk types have been developed. Even though cervical cancer is preventable, not all women are aware of this or how it can be prevented. Thus, it is essential for every nation to assess the level of knowledge among women of cervical cancer and HPV prevention. In this work, we assessed the level of awareness and attitudes of Greek female healthcare workers on cervical cancer and HPV prevention through the delivery of a validated questionnaire between March and June 2012 in three hospitals in Greece. Our results show that there exist gaps in the knowledge of women on this topic, especially in terms of the newest information on cervical cancer prevention through HPV testing and vaccination. In fact, only 80% of surveyed women knew about the existence of HPV testing. We propose that more information needs to be transmitted to Greek women and men on HPV testing and vaccination. Even though the incidence of cervical cancer is not extremely high in Greece, this number can easily change, especially in the face of the economic crisis and the increasing rates of migration, which can result in higher rates of HPV infection in the population if no measures for HPV prevention are implemented. Clinicopathological features of Egyptian colorectal cancer patients regarding somatic genetic mutations especially in KRAS gene and microsatellite instability status: a pilot study

EGYPTIAN JOURNAL OF MEDICAL HUMAN GENETICS

Background Colorectal cancer (CRC) is the third most common cause of cancer-related deaths which contributes to a significant public health problem worldwide with 1.8 million new cases and almost 861,000 deaths in 2018 according to the World Health Organization. It exhibits 7.4% of all diagnosed cancer cases in the region of the Middle East and North Africa. Molecular changes that happen in CRCs are chromosomal instability, microsatellite instability (MSI), and CpG island methylator phenotype. The human RAS family (KRAS, NRAS, and HRAS) is the most frequently mutated oncogenes in human cancer appearing in 45% of colon cancers. Determining MSI status across CRCs offers the opportunity to identify patients who are likely to respond to targeted therapies such as anti-PD-1. Therefore, a method to efficiently determine MSI status for every cancer patient is needed. Results KRAS mutations were detected in 31.6% of CRC patients, namely in older patients ($p = 0.003$). Codons 12 and 13 constituted 5/6 (83.3%) and 1/6 (16.7%) of all KRAS mutations, respectively. We found three mutations G12D, G12C, and G13D which occur as a result of substitution at c.35G>A, c.34G>T, and c.38G>A and have been detected in 4/6 (66.6%), 1/6 (16.7%), and 1/6 (16.7%) patients, respectively. Eleven (57.9%) patients had microsatellite instability-high (MSI-H) CRC. A higher percentage of MSI-H CRC was detected in female patients ($p = 0.048$). Eight patients had both MSI-H CRC and wild KRAS mutation with no statistical significance was found between MSI status and KRAS mutation in these studied patients. Conclusion In conclusion, considering that KRAS mutations confer resistance to EGFR inhibitors, patients who have CRC with KRAS mutation could receive more tailored management by defining MSI status. MSI-high patients have enhanced responsiveness to anti-PD-1 therapies. Thus, the question arises as to whether it is worth investigating this association in the routine clinical setting or not. Further studies with a larger number of patients are needed to assess the impact of MSI status on Egyptian CRC care.  BRCA founder mutations in Middle Eastern breast cancer patients
 using capture and Sanger sequencing analysis INTERNATIONAL JOURNAL
 OF CANCER English Article
 breast cancer; mutation; BRCA 1; BRCA 2 POPULATION-
 BASED SERIES; GERMLINE MUTATIONS; HEREDITARY BREAST; OVARIAN-
 CANCER; RISK; PREVALENCE; FREQUENCY; RECURRENT; WOMEN Ethnic
 differences of breast cancer genomics have prompted us to
 investigate the spectra of BRCA1 and BRCA2 mutations in different
 populations. The prevalence and effect of BRCA 1 and BRCA 2
 mutations in Middle Eastern population is not fully explored. To
 characterize the prevalence of BRCA mutations in Middle Eastern
 breast cancer patients, BRCA mutation screening was performed in
 818 unselected breast cancer patients using Capture and/or Sanger
 sequencing. 19 short tandem repeat (STR) markers were used for
 founder mutation analysis. In our study, nine different types of
 deleterious mutation were identified in 28 (3.4%) cases, 25
 (89.3%) cases in BRCA 1 and 3 (10.7%) cases in BRCA 2. Seven
 recurrent mutations identified accounted for 92.9% (26/28) of all
 the mutant cases. Haplotype analysis was performed to confirm
 c.1140 dupG and c.4136_4137delCT mutations as novel putative
 founder mutation, accounting for 46.4% (13/28) of all BRCA mutant
 cases and 1.6% (13/818) of all the breast cancer cases,
 respectively. Moreover, BRCA 1 mutation was significantly
 associated with BRCA 1 protein expression loss (p=0.0005). Our
 finding revealed that a substantial number of BRCA mutations were
 identified in clinically high risk breast cancer from Middle East
 region. Identification of the mutation spectrum, prevalence and
 founder effect in Middle Eastern population facilitates genetic
 counseling, risk assessment and development of cost-effective
 screening strategy. [Bu, Rong; Siraj, Abdul K.; Al-Obaisi,

NORTH-AFRICA; INFORMATION; PREVENTION; BEHAVIORS; FATALISM

Objective: To explore breast, colorectal, and cervical
cancer screening experiences among Arabic-speaking refugee women
in Massachusetts. Design: Qualitative descriptive. Setting: The
research was conducted in central Massachusetts, an area with a
large refugee population from the Middle East. Despite cancer
being the leading cause of death among Middle Eastern women aged
40 to 79 years, refugees experience significant disparities in
cancer screenings. These refugees often pass through intermediary
countries before permanently resettling, leading to preventive
care becoming a lower priority as other life stressors take
precedence. Participants: Eleven women participated. Participants
had an average age of 47 years; had come from Iraq, Syria, and
Egypt; and had been in the United States an average of 7 years.
Methods: In 2022, semistructured individual interviews were
conducted in person or via Zoom. An interview guide, constructed
based on components of the Health Equity Implementation Science
Framework and an expert panel of partners, refugee women, and
medical providers, was used. Conventional content analysis was
used to analyze the data. Results: Three themes emerged:
Facilitators of Cancer Screening, Barriers to Cancer Screening,
and Interpreter-Related Factors. Women positively described
providers' efforts to provide knowledge regarding screenings;
however, language barriers, the invasive nature of some
screenings, and scheduling appointments for screening posed
significant obstacles. Conclusion: This study highlights the
unique health challenges faced by Arabic-speaking refugee women,
focusing on their beliefs, experiences in clinical encounters, and
communication regarding cancer screenings. Nurses can address
these challenges by providing culturally sensitive care and
building relationships with community resources. [Zaidi, Maryum;

Diet impacts triple-negative breast cancer growth, metastatic potential, chemotherapy responsiveness, and doxorubicin-mediated cardiac dysfunction PHYSIOLOGICAL REPORTS English Article cardiac damage; doxorubicin; drug resistance; fish oil; lung metastases; Mediterranean diet; triple-negative breast cancer; Western diet RISK-FACTOR; OBESITY; CARDIOTOXICITY; SURVIVAL; WOMEN; ACID; RATS Anthracyclines are standard-of-care chemotherapy for the treatment of triple-negative breast cancer (TNBC). However, high anthracyclines cumulative doses increase heart failure risk. Designing therapeutic strategies that ameliorate cardiac toxicities without compromising oncologic efficacy are important to improve TNBC outcomes and survivorship. The purpose of this study was to determine the impact of diet on TNBC chemotherapeutic responsiveness and development of chemotherapy-induced cardiac damage. Female BALB/c mice fed a control, Western, Mediterranean, or Western + fish oil diet were injected with 1×10^6 4T1-luciferase TNBC into the mammary fat pad. Tumors grew for 21 days

before surgical tumor resection, then mice were treated with 3.3 mg/kg i.v. doxorubicin for 3 weeks. Vevo (R) cardiac ultrasound was performed. Female nu/nu mice were placed on diets before 1 x 10⁵ MDA-MB-231-luciferase TNBC were injected via the tail vein to induce the development of lung metastases. Mice were treated with saline or 3.3 mg/kg i.v. doxorubicin for 3 weeks, and the development of metastases visualized by IVIS (R). Consumption of a high-fat diet increased TNBC growth regardless of dietary pattern. Western diet-fed mice developed lung metastases sooner and displayed increased lung metastatic lesion formation, which was not observed in Mediterranean diet-fed mice. Western diet-fed animals displayed worse cardiac function when compared with Mediterranean diet-fed animals. Hearts from Western diet-fed animals displayed increased fibrosis. Diet represents a modifiable component directly impacting tumor growth, antitumor chemotherapy efficacy, and cardiac toxicities. Our data suggest that the Mediterranean diet may reduce lung metastatic lesions formation and prevent the development of cardiac toxicities.D [Ramirez,

Age-related Variation in Expression of Breast
Cancer Tumour Markers in Iranian Patients MIDDLE EAST JOURNAL
OF CANCER English Article
HER2; Breast cancer; Biomarkers; Ki-67; TP53; Triple
negative OVER-EXPRESSION; P53; WOMEN; CARCINOMA; HER-2/NEU;
PROGNOSIS; ACCUMULATION; ASSOCIATION; SURVIVAL; FEATURES

Background: There are believed to be several risk factors
affecting the prognosis of breast cancer through their effect on
the growth rate of tumour. In the present study, we investigated
estrogen receptor (ER), progesterone receptor (PR), human
epidermal growth factor receptor 2 (HER2), Ki-67, and tumor
protein P53 (TP53) as well-known biomarkers, particularly in
breast cancer prognosis, associated with age. Method: In a case-
control study, 406 breast cancer patients were considered
retrospectively. In order to extract the clinical and pathologic
data, we employed the patients' records. The extracted information
was compared between two groups: for patients under 40 (group I)
and above 40 years of age (group II). Herein, the researchers
performed statistical analysis using SPSS Ver16. Results: The most
prevalent type of cancer in both groups was found to be invasive
ductal carcinoma. The major method of treatment was modified
radical mastectomy. According to our observations, grade 3 breast
cancer was more common in group I. Lymph node involvement
significantly increased in group I, while oestrogen and
progesterone receptor expressions were less in this group. HER2,
TP53, and Ki-67 oncogenes were overexpressed in group I compared
with group II. Conclusion: Expression of HER2, TP53, and Ki-67
biomarkers and a reduction in the number of hormonal receptors in
younger patients (<40YO) indicated that breast cancer might be
more invasive in younger women with breast cancer and therefore,
they might have poorer prognosis and less favourable outcomes.

Tissue stores of individual monounsaturated fatty
 acids and breast cancer: the EURAMIC study AMERICAN JOURNAL OF
 CLINICAL NUTRITION English Article

monounsaturated fat; oleic acid; fatty
 acids; breast cancer; adipose tissue; olive oil; EURAMIC Study;
 Europe SUBCUTANEOUS ADIPOSE-TISSUE; DIETARY-FAT; OLIVE OIL;
 MAMMARY TUMORIGENESIS; RISK-FACTORS; DISEASE; CONSUMPTION; GREECE;
 COHORT The strongest evidence that monounsaturated fat may
 influence breast cancer risk comes from studies of southern
 European populations, in whom intake of oleic acid sources,
 particularly olive oil, appears protective. No previous study has
 examined the relation of adipose tissue fatty acid content to
 breast cancer in such a population. We used adipose biopsies with
 diverse fat intake patterns gathered in 5 European centers,
 including southern Europe (Malaga, Spain), to test the hypothesis
 that stores of oleic acid or other monounsaturates are inversely
 associated with breast cancer. Gluteal fat aspirates were obtained
 from 291 postmenopausal incident breast cancer patients and 351
 control subjects, frequency-matched for age and catchment area.
 Logistic regression was used to model breast cancer by
 monounsaturates, with established risk factors controlled for.
 Oleic acid showed a strong inverse association with breast cancer
 in the Spanish center. The odds ratio for the difference between
 75th and 25th percentiles was 0.40 (95% CI: 0.28, 0.58) in Malaga
 and 1.27 (0.88, 1.85) in all other centers pooled, with a peak at
 2.36 (1.01, 5.50) for Zeist. Palmitoleic and myristoleic acids
 showed evidence of an inverse association outside Spain, and cis-
 vaccenic acid showed a positive association in 3 centers. These
 data do not support the hypothesis that increasing tissue stores
 of oleic acid are protective against breast cancer in non-Spanish
 populations, This finding implies that the strong protective
 associations reported for olive oil intake in dietary studies may
 be due to some other protective components of the oil and not to
 the direct effect of oleic acid uptake. Alternatively, high olive
 oil intake may indicate some other protective aspect of the
 lifestyle of these women. Univ N Carolina, Dept Epidemiol,

Olive oil intake and breast

cancer risk in the Mediterranean countries of the European Prospective Investigation into Cancer and Nutrition study

INTERNATIONAL JOURNAL OF CANCER English

Article breast cancer; olive

oil; EPIC cohort study DIET Although there is some evidence suggesting that olive oil could reduce breast cancer (BC) risk, the epidemiological data are still relatively limited, not entirely consistent and mainly based on casecontrol studies. Therefore, we prospectively assessed the association between olive oil and BC risk in postmenopausal women from the Mediterranean cohorts within the European Prospective Investigation into Cancer and Nutrition. The analysis included 62,284 postmenopausal women recruited from Spain, Italy and Greece who had complete dietary data (collected from validated country-specific dietary questionnaires). The risk of BC (overall and by hormone receptor subtypes) was assessed using hazards ratios (HRs) obtained from Cox proportional hazards regression, while adjusting for known BC

risk factors. After a mean follow-up of 9 years, 1,256 women were diagnosed with a primary incident invasive BC. The multivariate HRs for BC risk by olive oil intake (highest vs. lowest tertile of g/day/2,000 kcal) were 1.07 (95% CI = 0.911.25) in the adjusted model, 1.06 (95% CI = 0.911.24) in the model additionally adjusted for reproductive-related factors and 1.10 (95% CI = 0.921.31) for the model additionally adjusted for dietary factors. There was no association between olive oil and risk of estrogen or progesterone receptor-positive tumors, but a suggestion of a negative association with estrogens and progesterone receptor-negative tumors. The results from our prospective study showed that olive oil consumption during adult life was not associated with the risk of BC. However, larger prospective studies are still needed to explore possible differences related to hormone receptor status.

Cervix Uteri Cancer in Lebanon: Incidence, Temporal Trends, and Comparison to Countries From Different Regions in the World CANCER CONTROL English Article

cervical cancer; epidemiology; cancer screening; incidence; prevention; cancer detection; risk factors EXTENDED MIDDLE-EAST; HUMAN-PAPILLOMAVIRUS; NORTH-AFRICA;

PREVALENCE; BEIRUT; CHLAMYDIA; COVERAGE; TOBACCO; WOMEN

Background Invasive cervix uteri cancer is the fourth most common malignancy in women globally. This study investigates the incidence and trends of cervix uteri cancer in Lebanon, a country in the Middle East, and compares these rates to regional and global ones. Methods Data on cervix uteri were obtained from the Lebanese national cancer registry for the currently available years 2005 to 2016. The calculated age-standardized incidence and age-specific rates were expressed as per 100,000 population. Results From 2005 to 2016, cervix uteri cancer was the tenth most common cancer among women. Its age-standardized incidence rate fluctuated narrowly between 3.5 and 5.7 per 100,000, with the lowest rate in 2013 and the highest rate in 2012. The age-specific incidence rate had 2 peaks, the highest peak at age group 70-74 years and the second at age group 50-59 years. The annual percent change (+.05%) showed a non-statistically significant trend of increase. The age-standardized incidence rate of cervix uteri cancer in Lebanon was comparable to that of the Western Asia region that has the lowest incidence rate worldwide. The rate was intermediate as compared to other countries in the Middle East and North Africa Region and relatively similar to the ones in Australia, North America, and some Western European countries. Conclusion The incidence rates of invasive cervix uteri are low in Lebanon. This could be attributed to the low prevalence of human papilloma virus infection and other sexually transmitted infections among Lebanese women, and the opportunistic screening practices. It is important to adopt a comprehensive approach to decrease the potential burden of cervix uteri, especially with the rising patterns of risky sexual behaviors. This includes improving awareness, enhancing access to preventive services, developing clinical guidelines, and training health care providers on these guidelines. Downregulation of external death receptor genes FAS and DR5
in colorectal cancer samples positive for human papillomavirus
infection PATHOLOGY RESEARCH AND PRACTICE English

Article Colorectal cancer;

Human papillomavirus; Apoptosis POLYMERASE-CHAIN-REACTION;
MEDIATED APOPTOSIS; COLON-CANCER; DNA; ONCOPROTEINS; ASSOCIATION;
VIRUS; ADENOCARCINOMA; PREVALENCE; CARCINOMAS Aim: Human

papillomaviruses (HPV) have frequently been detected in colorectal cancer tumor samples, and may play a role in the pathogenesis of colorectal cancer. This study was designed to investigate the presence of DNA and RNA for the high-risk HPV genotypes 16 and 18 in samples of colorectal cancer tumors and adjacent normal tissues. We also investigated the expression of proapoptotic genes in HPV-positive colorectal tumors compared to normal tissue samples. Methods: Samples of tumoral and adjacent normal tissues were fresh-frozen, and HPV DNA was identified by nested and semiquantitative PCR. Real time PCR was used to quantitatively compare the expression of HPV-18 E6 and nine proapoptotic genes in HPV-positive tumors and samples of adjacent normal tissue. Results: HPV-16 DNA was found in 10.5% of the tumor samples, and HPV-18 DNA was found in 23.6% of the samples. Real time PCR results showed lower expression of the E6 gene in HPV-positive tumors than in adjacent normal tissue. The expression of two proapoptotic genes, FAS and DR5, was significantly lower in tumor samples than in adjacent normal tissues. Conclusions: HPV infection, especially HPV-18, may play a role in colorectal cancer tumorigenesis by downregulating death receptor genes and interfering with the extrinsic pathway of apoptosis. IVS10-6T>G, an ancient ATM germline mutation linked with breast cancer HUMAN MUTATION English Article

ATM; haplotype; breast cancer; germline mutation; founder; Dutch; German; ataxia-telangiectasia;

AT ATAXIA-TELANGIECTASIA LOCUS; PROTEIN TRUNCATION TEST; RAPID
DETECTION; GENE-MUTATIONS; FAMILIES; HETEROZYGOSITY;
IDENTIFICATION; POPULATIONS; HAPLOTYPES; DEFICIENCY Patients
with autosomal recessive multisystemic disorder ataxia-
telangiectasia are homozygous or compound heterozygous for
mutations in the ataxia-telangiectasia mutated (ATM) gene.
Heterozygous carriers of an ATM germline mutation have an
increased susceptibility for breast cancer. The subject of this
study is one particular germline mutation, the ATM exon 11 splice-
site mutation IVS10-6T>G, that has been identified as being
associated with an increased risk for breast cancer both in the
general population and in high risk breast cancer families. We
investigated the natural history of this mutation, i.e., whether
it is frequently arising de novo in a population, or whether it
can be traced back to a single ancient mutational event.
Genotyping of a number of polymorphic markers (two extragenic and
two intragenic. microsatellite loci, a single nucleotide
insertion/deletion polymorphism, and a dinucleotide
insertion/deletion polymorphism) was performed in 18 samples from
different populations carrying the IVS10-6T>G mutation (17
unrelated breast cancer patients who were heterozygous carriers of
this mutation and a single A-T patient who was homozygous for the
IVS10-6T>G mutation). The same markers were also genotyped among
39 unrelated healthy individuals without this mutation. Haplotype
analyses revealed one common ancestor in all mutation carriers. By
means of a maximum likelihood method, we estimated the age of this
mutation to be approximately 2,000 generations. We provide
evidence that the IVS10-6T>G mutation occurred only once during
human evolution, at least 50,000 years ago. Our results predict
that this mutation could be widely distributed across Europe and,
probably, the Middle East and Western Asia. (C) 2003 Wiley Liss,

D'Amico, Nicolo The Health Problems at the Landing of
the Migrants in Lampedusa from 2011 to June 2019: Analysis of the

Abortion spontaneous; Carbon monoxide poisoning; Fracture bone; Human migration; Neurocysticercosis; Seizures; Suicide attempted; Tuberculosis; Rhabdomyolysis

TUBERCULOSIS; REFUGEES; JANUARY This is a study on the migrants hospitalized from 2011 to June 2019, coming from Lampedusa, a small isle in the Mediterranean Sea, called Europe's door, where they arrive along the Sicily Canal Central Route. The physicians of 118 emergency service required the hospitalization for 775 patients (440 men and 335 women) in 6 Sicilian hospitals, mainly in Palermo: 203 in 2011; 62 in 2012; 95 in 2013; 45 in 2014, 184 in 2015; 72 in 2016, 73 in 2017, 35 in 2018, and 6 from January to June 2019. The mean age was 25 years; underage children were about 10%. Their diseases were very similar over the years, irrespective of their country provenance; 227 patients were hospitalized for obstetrics-gynecology problems, 167 infectious diseases (21 TB), 125 orthopedic, 92 intensive care, 89 medicine-cardiology, and 75 for dermatology lesions and burns. In decreasing order, the more frequent provenances were West, Horn, and North Africa and Middle East. The knowledge of the health problems is very important to study of the best practices to activate for these patients. First, help the migrants while they are in the sea, to allow the reduction of the serious health problems, related to the hardships and duration of the long journey, main risk factors for their hospitalization; second, optimize the moment of landing of migrants, for disseminating information on the basic principles of health education. In relation to their young age, these migrants have the mission of perpetuating their ethnic groups, at risk of annihilation by the war violence.

Diet and a Posteriori Derived Dietary Patterns with Breast and Lung Cancer Risk: A Case-Control Study NUTRIENTS

English Article

breast

cancer; lung cancer; dietary pattern; Mediterranean diet; adults
INDEX; ADHERENCE; COHORT; WOMEN; FOOD Lung cancer in men and breast cancer in women are the most commonly diagnosed cancers in Poland and worldwide. Results of studies involving dietary patterns (DPs) and breast or lung cancer risk in European countries outside the Mediterranean Sea region are limited and inconclusive. This study aimed to develop a 'Polish-adapted Mediterranean Diet' ('Polish-aMED') score, and then study the associations between the 'Polish-aMED' score and a posteriori-derived dietary patterns with breast or lung cancer risk in adult Poles. This pooled analysis of two case-control studies involved 560 subjects (280 men, 280 women) aged 40-75 years from Northeastern Poland. Diagnoses of breast cancer in 140 women and lung cancer in 140 men were found. The food frequency consumption of 21 selected food groups was collected using a 62-item Food Frequency Questionnaire (FFQ)-6. The 'Polish-adapted Mediterranean Diet' score which included eight items-vegetables, fruit, whole grain, fish, legumes, nuts and seeds-as well as the ratio of vegetable oils to animal fat and red and processed meat was developed (range: 0-8 points). Three DPs were identified in a Principal Component Analysis: 'Prudent', 'Non-healthy', 'Dressings and sweetened-low-fat dairy'. In a multiple logistic regression analysis, two models were created: crude, and adjusted for age, sex, type of cancer, Body Mass Index (BMI), socioeconomic status (SES) index, overall physical activity, smoking status and alcohol abuse. The risk of breast or lung cancer was lower in the average (3-5 points) and high (6-8 points) levels of the 'Polish-aMED' score compared to the low (0-2 points) level by 51% (odds ratio (OR): 0.49; 95% confidence interval (CI): 0.30-0.80; $p < 0.01$; adjusted) and 63% (OR: 0.37; 95% CI: 0.21-0.64; $p < 0.001$; adjusted), respectively. In the middle and upper tertiles compared to the bottom tertile of the 'Prudent' DP, the risk of cancer was lower by 38-43% (crude) but was not significant after adjustment for confounders. In the upper compared to the bottom tertile of the 'Non-healthy' DP, the risk of cancer was higher by 65% (OR: 1.65; 95% CI: 1.05-2.59; $p < 0.05$; adjusted). In conclusion, the Polish adaptation of the Mediterranean diet could be considered for adults living in non-Mediterranean countries for the prevention of the breast or lung cancers. Future studies should explore the role of a traditional Mediterranean diet fitted to local dietary patterns of non-Mediterranean Europeans in cancer prevention. 16 sub-lineage dispersal and cervical cancer risk worldwide: Whole
viral genome sequences from 7116 HPV16-positive women

PAPILLOMAVIRUS RESEARCH English Article

HPV16; Cervical cancer; HPV

carcinogenesis; HPV epidemiology; HPV genomics; Whole virus genome
sequencing TYPE-18 VARIANTS; NATURAL-HISTORY; NEOPLASIA;

INFECTION; E6; ADENOCARCINOMA; CLASSIFICATION; POLYMORPHISMS;

PERSISTENCE; PREVALENCE Background: Human papillomavirus

(HPV)16 can be separated into genetic sub-lineages (A1-4, B1-4,
C1-4, D1-4) which may have differential cervical cancer risk.

Methods: A next-generation sequencing assay was used to whole-
genome sequence 7116 HPV16-positive cervical samples from well-
characterised international epidemiological studies, including

2076 controls, 1878 squamous cell carcinoma (SCC) and 186
adenocarcinoma/adenosquamous cell carcinoma (ADC), and to assign
HPV16 sub-lineage. Logistic regression was used to estimate

region-stratified country-adjusted odds ratios (OR) and 95%CI.

Results: A1 was the most globally widespread sub-lineage, with
others showing stronger regional specificity (A3 and A4 for East
Asia, B1-4 and C1-4 for Africa, D2 for the Americas, B4, C4 and D4

for North Africa). Increased cancer risks versus A1 were seen for
A3, A4 and D (sub)lineages in regions where they were common: A3
in East Asia (OR = 2.2, 95%CI:1.0-4.7); A4 in East Asia (6.6, 3.1-

14.1) and North America (3.8, 1.7-8.3); and D in North (6.2, 4.1-
9.3) and South/Central America (2.2, 0.8-5.7), where D lineages
were also more frequent in ADC than SCC (3.2, 1.5-6.5; 12.1, 5.7-

25.6, respectively). Conclusions: HPV16 genetic variation can
strongly influence cervical cancer risk. However, burden of
cervical cancer attributable to different sub-lineages worldwide

is largely driven by historical HPV16 sub-lineage dispersal.

 Holmes, MD Fung, TT; Hu, FB; McCullough, ML;
 Newby, PK; Willett, WC; Holmes, MD Diet quality is
 associated with the risk of estrogen receptor-negative breast
 cancer in postmenopausal women. JOURNAL OF NUTRITION
 English Article breast
 cancer; diet; nutrition; estrogen receptor CORONARY-HEART-
 DISEASE; MAJOR CHRONIC DISEASE; POOLED ANALYSIS; COHORT;
 QUESTIONNAIRE; CONSUMPTION; VEGETABLES; MORTALITY; PATTERNS;
 FRUITS Emerging evidence suggests that diet quality indices
 may serve as prognostic indicators of disease. However, the
 ability of these indices to predict breast cancer risk has not
 been evaluated previously. We assessed the association between
 several diet quality scores and the risk of breast cancer in
 postmenopausal women. The indices we used were the Healthy Eating
 Index (HEI), Alternate Healthy Eating Index (AHEI), Diet Quality
 Index-Revised (DQI-R), Recommended Food Score (RFS), and the
 alternate Mediterranean Diet Score (aMed). We calculated diet
 quality indices from dietary information collected in FFQ
 administered 5 times between 1984 and 1998 among women in the
 Nurses' Health Study cohort. Relative risks (RR) were computed
 using Cox proportional hazards models and adjusted for known risk
 factors for breast cancer. Separate analyses were conducted for
 estrogen receptor positive (ER+) and negative (ER-) tumors.
 Between 1984 and 2002, we documented 3580 cases of breast cancer,
 of which 2367 were ER+, and 575 were ER-. We did not observe any
 association between the diet quality indices and total or ER+
 breast cancer risk. However, for ER- breast cancer, after
 adjusting for potential confounders, the FRR comparing highest to
 lowest quintiles were 0.78 (95% CI = 0.59-1.04, P for trend =
 0.01) for the AHEI, 0.69 (95% CI = 0.51-0.94, P for trend = 0.003)
 for the RFS, and 0.79 (95% CI = 0.60-1.03, P for trend = 0.03) for
 the aMed. These observations appeared to be the result of an
 inverse association (P for trend = 0.01) with the vegetable
 component of the scores. We conclude that women who scored high in
 AHEI, RFS, and aMed had a lower risk of ER- breast cancer. The HEI
 and DQI-R appeared to be of limited value in predicting breast
 cancer risk. Simmons Coll, Dept Nutr, Boston, MA 02115 USA;

G.; Ghali, Sarah A.; Meyls, Hannah M.; Ouazzani, Nouredine; Laziri, Fatiha; Barber, Amorette Olive oil varieties cultivated in Morocco reduce reactive oxygen species and cell viability of human cervical cancer cells MEDITERRANEAN JOURNAL OF NUTRITION AND METABOLISM English Article

Antioxidant; cervical cancer; gene expression; olive oil VIRGIN OLIVE; OXIDATIVE STRESS; DIETARY LIPIDS; PHENOLS; ANTIOXIDANT; EXPRESSION; CARCINOMA; LIVER; ACID BACKGROUND: The Moroccan diet incorporates olive oil as the primary source of fat and may reduce cancer risk. However, different olive oil varieties often have varying levels of anti-cancer polyphenols and thus have unique biologic effects. OBJECTIVE: The anti-cancer activity of five varieties of extra virgin Moroccan-cultivated olive oil on human cervical cancer cells was assessed in vitro. METHODS: The presence of phenolic compounds in five olive oil varieties cultivated in Morocco was analyzed using HPLC. Human cervical cancer cell lines (HeLa, SKG-II, and HCS-2) were incubated with the olive oils and cell viability was measured by MTT assay, reactive oxygen species were measured using the CellRox assay, and gene expression was measured by RT-PCR. RESULTS: Each of the five Moroccan-cultivated olive oil varieties had a unique composition of phenolic compounds. Incubation with the olive oils reduced cell viability and reactive oxygen species in human cervical cancer cells. The expression of genes involved in cervical cancer carcinogenesis and cell cycle were also altered. All five olive oil varieties decreased expression of E6, E7, p16, p63, and NRP2 and increased expression of IVL and miR 331-3p. CONCLUSIONS: Use of Moroccan-cultivated olive oils could be a promising anti-cancer agent for cervical cancer. Characterizing inflammatory breast cancer among Arab
Americans in the California, Detroit and New Jersey Surveillance,
Epidemiology and End Results (SEER) registries (1988-2008)
SPRINGERPLUS English Article
Inflammatory breast cancer; Arab; Race;
Hierarchical logistic regression MENOPAUSAL STATUS; RISK-FACTORS;
WOMEN; CARCINOMA; SURVIVAL Introduction: Inflammatory breast
cancer (IBC) is characterized by an apparent geographical
distribution in incidence, being more common in North Africa than
other parts of the world. Despite the rapid growth of immigrants
to the United States from Arab nations, little is known about
disease patterns among Arab Americans because a racial category is
rarely considered for this group. The aim of this study was to
advance our understanding of the burden of IBC in Arab ethnic
populations by describing the proportion of IBC among different
racial groups, including Arab Americans from the Detroit, New
Jersey and California Surveillance, Epidemiology and End Results
(SEER) registries. Methods: We utilized a validated Arab surname
algorithm to identify women of Arab descent from the SEER
registries. Differences in the proportion of IBC out of all breast
cancer and IBC characteristics by race and menopausal status were
evaluated using chi-square tests for categorical variables, t-
tests and ANOVA tests for continuous variables, and log-rank tests
for survival data. We modeled the association between race and IBC
among all women with breast cancer using hierarchical logistic
regression models, adjusting for individual and census tract-level
variables. Results: Statistically significant differences in the
proportion of IBC out of all breast cancers by race were evident.
In a hierarchical model, adjusting for age, estrogen and
progesterone receptor, human epidermal growth receptor 2, registry
and census-tract level education, Arab-Americans (OR = 1.5, 95% CI
= 1.2,1.9), Hispanics (OR= 1.2, 95% CI = 1.1,1.3), Non-Hispanic
Blacks (OR = 1.3, 95% CI = 1.2, 1.4), and American
Indians/Alaskans (OR= 1.9, 95% CI = 1.1, 3.4) had increased odds
of IBC, while Asians (OR = 0.6, 95% CI = 0.6, 0.7) had decreased
odds of IBC as compared to Non-Hispanic Whites. Conclusions: IBC
may be more common among certain minority groups, including Arab
American women. Understanding the descriptive epidemiology of IBC
by race may generate hypotheses about risk factors for this
aggressive disease. Future research should focus on etiologic
factors that may explain these differences. [Hirko, Kelly A.;

A. Middle East Netw Identification and management of Lynch syndrome in the Middle East and North African countries: outcome of a survey in 12 countries FAMILIAL CANCER English Article

Colorectal cancer; Lynch syndrome; Middle Eastern countries; North African countries COLORECTAL-CANCER; HEREDITARY; PREVALENCE; MORTALITY; FAMILIES Background Lynch syndrome (LS), the most common inherited form of colorectal cancer (CRC), is responsible for 3% of all cases of CRC. LS is caused by a mismatch repair gene defect and is characterized by a high risk for CRC, endometrial cancer and several other cancers. Identification of LS is of utmost importance because colonoscopic surveillance substantially improves a patient's prognosis. Recently, a network of physicians in Middle Eastern and North African (ME/NA) countries was established to improve the identification and management of LS families. The aim of the present survey was to evaluate current healthcare for families with LS in this region. Methods A questionnaire was developed that addressed the following issues: availability of clinical management guidelines for LS; attention paid to family history of cancer; availability of genetic services for identification and diagnosis of LS; and assessment of knowledge of LS surveillance. Members of the network and authors of recent papers on LS from ME/NA and neighbouring countries were invited to participate in the survey and complete the online questionnaire. Results A total of 55 individuals were invited and 19 respondents from twelve countries including Algeria, Azerbaijan, Cyprus, Egypt, Iran, Jordan, Kuwait, Lebanon, Morocco, Palestine, Tunisia, and Turkey completed the questionnaire. The results showed that family history of CRC is considered in less than half of the surveyed countries. Guidelines for the management of LS are available in three out of twelve countries. The identification and selection of families for genetic testing were based on clinical criteria (Amsterdam criteria II or Revised Bethesda criteria) in most countries, and only one country performed universal screening. In most of the surveyed countries genetic services were available in few hospitals or only in a research setting. However, surveillance of LS families was offered in the majority of countries and most frequently consisted of regular colonoscopy. Conclusion The identification and management of LS in ME/NA countries are suboptimal and as a result most LS families in the region remain undetected. Future efforts should focus on increasing awareness of LS amongst both the general population and doctors, and on the improvement of the infrastructure in these countries. CERVICAL CYTOLOGY; IRANIAN WOMEN; PAP-SMEAR; PREVALENCE;
EPIDEMIOLOGY; VACCINATION; TEHRAN; DNA Background:HPV is the main
cause of cervical cancer. Determining the geographic distribution
of HPV genotypes is a major step in the implementation of cervical
cancer screening. This study aimed to evaluate the prevalence of
HPV and its high-risk genotypes in Middle Eastern
countries. Materials & methods: MEDLINE, ISI Web of Science, PubMed,
EMBASE, Scopus and ProQuest were searched from 2005 to 2018. The
quality of the studies was determined by Strengthening the
Reporting of Observational Studies in Epidemiology checklist.
Fixed/random effects models were conducted to estimate the pooled
prevalence. Results: The pooled prevalence of HPV was 12.3 and 5.2%.
The prevalence of HPV in Africa (22%) was higher than that in
Eurasia (8.3%) and Asia (12.6%). The prevalence of HPV was 14.4,
8.3, 22 and 10.2% in Iran, Turkey, Egypt and Arab countries,
respectively. The prevalence of high-risk-HPV in the above-
mentioned countries was 6.5, 6.2, 6.5 and
3.7%. Conclusion: Prevalence of HPV was increased in the Middle
East. This highlights the need for public education, screening and
vaccination programs. [Zare, Elham] Shahid Beheshti Univ Med Sci,

intervention program's on breast cancer survivors' cardiometabolic
health: Two-year follow-up HELIYON English

Article Breast cancer
survivors; Home-based lifestyle intervention; Aerobic exercise;
Mediterranean diet; COVID-19PHYSICAL-ACTIVITY; METABOLIC SYNDROME;
EXERCISE; PROGNOSIS; OBESITY; GUIDELINES; ADHERENCE; INSULIN;
GLUCOSE; RISK The purpose of this study is to assess the
cardiometabolic responses of a lifestyle intervention (LI)
conducted at home among breast cancer (BC) survivors during the
two years of COVID-19 pandemic. A 3-month LI focused on diet and
exercise was performed on thirty BC survivors (women; stages 0-II;
non-metastatic; aged 53.6 +/- 7.6 years; non-physically active)
with a risk factor related to metabolic/endocrine diseases.
Anthropometrics, cardiorespiratory fitness (V O2max), physical
activity level (PAL), adherence to the Mediterranean diet (MeDiet
modified questionnaire), and several biomarkers (i.e., glycemia,
insulin, insulin resistance [HOMA-IR] index, triglycerides, high-
[HDL] and low-[LDL] density lipoproteins, total cholesterol,
proges-terone, testosterone, and hs-troponin) were evaluated
before and 3-, 6-, 12-, and 24-month after the LI. Beneficial
effects of the LI were observed on several variables (i.e., body
mass index, waist circumference, MeDiet, PAL, V O2max, glycemia,
insulin, HOMA-IR index, LDL, total cholesterol, triglycerides,
testosterone) after 3-month. The significant effect on
Mediterranean diet adherence and V O2max persisted up to the 24-
month follow-up. Decreases in HOMA-IR index and tri-glycerides
were observed up to 12-month, however did not persist afterward.
This study provides evidence on the positive association between
LI and cardiometabolic health in BC survivors. [Natalucci,

 Consumption of olive oil and risk of breast cancer in US women: results from the Nurses' Health Studies
 BRITISH JOURNAL OF CANCER English Article
 MEDITERRANEAN DIET;
 CARDIOVASCULAR RISK; FATTY-ACIDS; METAANALYSIS Background Olive oil consumption may reduce breast cancer risk, but it is unclear whether olive oil is beneficial for breast cancer prevention in populations outside of Mediterranean regions, namely in the U.S., where the average consumption of olive oil is low compared with Mediterranean populations. We examined whether olive oil intake was associated with breast cancer risk in two prospective cohorts of U.S. women. Methods We used multivariable-adjusted time-varying Cox proportional hazards models to estimate hazard ratios (HR) and 95% confidence interval (CI) for breast cancer among 71,330

(Nurses' Health Study, 1990-2016) and 93,295 women (Nurses' Health Study II, 1991-2017) who were free of cancer at baseline. Diet was assessed by a validated semi-quantitative food frequency questionnaire every 4 years. Results During 3,744,068 person-years of follow-up, 9,638 women developed invasive breast cancer. The multivariable-adjusted HR (95% CI) for breast cancer among women who had the highest consumption of olive oil (>1/2 tablespoon/d or >7 g/d) compared with those who never or rarely consumed olive oil, was 1.01 (0.93, 1.09). Higher olive oil consumption was not associated with any subtype of breast cancer. Conclusion We did not observe an association between higher olive oil intake and breast cancer risk in two large prospective cohorts of U.S. women, whose average olive oil consumption was low. Prospective studies are needed to confirm these findings and to further investigate whether different varieties of olive oil (e.g., virgin and extra virgin olive oil) may play a role in breast cancer risk. virgin olive oils; breast cancer; antitumor; proliferation; apoptosis; DNA damage; comet assay VIRGIN OLIVE OIL; OXIDATIVE DNA-DAMAGE; MEDITERRANEAN DIET; ANTIOXIDANT; PROLIFERATION; POTENTIATION; INHIBITION; PREVENTION; OLEUROPEIN; PROTECTS Several studies relate Mediterranean diet and virgin olive oil (VOO) intake with lower risk of several chronic diseases, including breast cancer. Many of them described antitumor properties of isolated minor compounds present in VOO, but beneficial properties of VOO arise from the effects of all its compounds acting together. The aim of the present study was to test the antitumor effects of two minor compounds from VOO (hydroxytyrosol (HT) and squalene (SQ)) on highly metastatic human breast tumor cells (MDA-MB-231) when acting in combination. Both isolated compounds were previously analyzed without showing any antitumoral effect on highly invasive MDA-MB-231 breast cancer cells, but the present results show that HT at 100 μ M, combined with different concentrations of SQ, could exert antitumor effects. When they are combined, HT and SQ are able to inhibit cell proliferation, promoting apoptosis and DNA damage in metastatic breast cancer cells. Therefore, our results suggest that the health-promoting properties of VOO may be due, at least in part, to the combined action of these two minor compounds.

 J La Foresta, D; Buonocore, MN La Foresta,
 Daniela; Buonocore, Maria Nicola Mediterranean
 migrations: NGO as the voice of the voiceless?The role of NGOs in
 communicating Mediterranean migration effectively: challenges and
 opportunities CIVIL SZEMLE English Article
 Migration flows; Mediterranean
 Sea; Search and Rescue Operations/(SAR operations); NGOs'
 strategies RESCUE; SEAThe Mediterranean Sea has always
 represented a unique melting pot of cultures and peoples, holding
 a strategic position: since the mid-1990s it has been the
 preferred route for migrants to reach the European continent.
 Adverse weather conditions overcrowded and illegal routes, as well
 as the difficult management of the emergency by the EU, make the
 Mediterranean one of the most dangerous routes, with reports of
 migrant accidents being an everyday occurrence. Since 2014,
 approximately 29.000 migrants have gone missing or died in the
 Mediterranean, with the highest number of fatalities recorded in
 2016 and the central route (UNHCR, 2022). The complexity of the
 situation indicates how it cannot be solved solely by the
 countries most affected by the phenomenon: indeed, cooperation and
 coordination with states, NGOs, and other maritime agencies are
 nec-essary. NGOs play a central role in the management of the
 situation, with the Council of Europe calling on states to
 cooperate constructively with NGOs to ensure the effective
 protection of human rights. Approximately 38 NGO ships conducted
 SAR operations in the Mediterranean Sea between 2016 and 2022
 (FRA). This research aims to analyze the online communication of
 the pre-eminent NGOs that operate in the Mediterranean Sea.
 Greater importance is attributed to communication strategies:
 through them, organiza-tions can spread their values and promote
 their actions, while raising public awareness. Thus, the focus is
 on the core online communication tactics used to achieve their
 goals. [La Foresta, Daniela] Univ Naples Federico II, Dept

 J Ganjavi, M; Faraji, B Ganjavi, Maryam;
 Faraji, Bahram Late effect of the food consumption on
 colorectal cancer rate INTERNATIONAL JOURNAL OF FOOD SCIENCES AND
 NUTRITION English Article
 Colorectal cancer; incidence; risk factor; food
 availability DIETARY PATTERNS; MEAT CONSUMPTION; MEDITERRANEAN
 DIET; RED MEAT; RISK; METAANALYSIS; ASSOCIATION; MORTALITY;
 ADENOMAS; POULTRY Studies have suggested that higher meat
 intake may increase colorectal cancer (CRC) risk while higher
 vegetable intake may reduce this risk. There is a substantial lag
 between the time of exposure to a risk factor (or protective
 factor) and incidence of cancer. For CRC, in particular, the time
 from formation of adenoma to occurrence of CRC takes from 10 to 15
 years, or even more. This study correlates food disappearance data
 per capita for vegetable and meat with future age-adjusted CRC
 rates in USA. The lag weights, with a high confidence, showed that
 there is a positive correlation between the red meat availability
 and CRC age-adjusted incidence rates with a lag of at least 17
 years and an Almon polynomial degree of 2. Conversely, there was a
 negative correlation between vegetables availability and future
 age-adjusted incidence rates of CRC. [Ganjavi, Maryam; Faraji,

 Exposure to water-pipe smoking dysregulates a set of genes
 associated with breast cancer development and an unfavorable
 outcome CLINICAL CANCER INVESTIGATION JOURNAL
 English Article Breast
 cancer; gene deregulation; mammary epithelial cells; smoking;
 water-pipe EPITHELIAL-MESENCHYMAL TRANSITION; DIFFERENTIALLY
 EXPRESSED GENES; CIGARETTE-SMOKING; TOBACCO SMOKING; POOR-
 PROGNOSIS; OVARIAN-CANCER; STEM-CELLS; ACTIVATION; CHEMOKINE;
 INVASION Background: Water-pipe smoking (WPS), a predominant

method of tobacco consumption, is common amongst young females in the Middle East. WPS smoke consists of toxins analogous to the ones that exist in cigarette smoke and frequently correlates with the onset of several types of human cancers including breast. However, the potential target genes and their underlying mechanisms in the initiation and/ or progression of human cancers, especially breast, due to WPS exposure are still unknown.

Materials and Methods: In this investigation, we explored the effect of WPS chronic exposure on human normal mammary epithelial cells and analyzed alterations in the differentially ex-pressed gene (DEG) targets using the NanoString nCounter PanCancer Pathways Panel consisting of 770 gene transcripts and a quantitative real-time polymerase chain reaction (PCR) analysis. **Results:** Our NanoString analysis identified 13 genes dysregulated under the effect of WPS exposure involved in regulating signal transduction, cell cycle, cell motility, proliferation and migration/invasion as well as the inflammatory response. We further performed an in silico analysis to investigate the effect of the identified genes in the prognosis of breast cancer patients and reported those DEGs that directly correlated with smoking and were upregulated in breast cancer in comparison with normal tissue. Moreover, the Kaplan-Meier curve analysis showed a significant correlation between WPS-dysregulated genes (MX1, CCL8, GNGT1 and MMP9) and relapse-free survival in breast cancer patients. **Conclusions:** Our data clearly suggest that exposure to WPS can alter the expression of key regulator genes involved in the pathogenesis of breast cancer, thereby affecting the breast cancer prognosis.

 Trends of cervical cancer at global, regional,
 and national level: data from the Global Burden of Disease study
 2019 BMC PUBLIC HEALTH English Article

Cervical cancer; Global burden of disease; Quality-adjusted life years; Global Health; Health services HUMAN-PAPILLOMAVIRUS; MIDDLE-EAST; WOMEN; PREVENTION; STATISTICS; MORTALITY; PATTERNS; VACCINE; IMPACT; RISK

Background Cervical cancer is an important global health problem. In this study we aimed to analyze trends in cervical cancer at the global, regional, and national levels from 1990 to 2019, to inform health service decision-making. Methods Data on cervical cancer was extracted from the Global Burden of Disease study, 2019. Trends in cervical cancer burden were assessed based on estimated annual percentage change (EAPC) and age-standardized rate (ASR). Results Globally, decreasing trends were observed in incidence, death, and disability adjusted life years (DALYs) of cervical cancer from 1990 to 2019, with respective EAPCs of - 0.38 (95% confidence interval [CI]: - 0.41 to - 0.34), - 0.93 (95%CI: - 0.98 to - 0.88), and - 0.95 (95 CI%: - 1.00 to - 0.90). Meanwhile, decreasing trends were detected in most sociodemographic index (SDI) areas and geographic regions, particularly death and DALYs in Central Latin America, with respective EAPCs of - 2.61 (95% CI: - 2.76 to - 2.46) and - 2.48 (95% CI: - 2.63 to - 2.32); however, a pronounced increasing trend in incidence occurred in East Asia (EAPC = 1.33; 95% CI: 1.12 to 1.55). At the national level, decreasing trends in cervical cancer were observed in most countries/territories, particularly DALYs in the Maldives (EAPC = - 5.06; 95% CI: - 5.40 to - 4.72), Whereas increasing trends were detected in Lesotho, Zimbabwe, and Bulgaria. Conclusions Slowly decreasing trends in cervical cancer were detected worldwide from 1990 to 2019. Cervical cancer remains a substantial health problem for women globally, requiring more effective prevention and control strategies. adherence to Western dietary pattern increases breast cancer risk
(an EPIC-Spain study) MATURITAS English Article

Dietary patterns; Diet; Western; Mediterranean; Breast neoplasms WOMEN; MENOPAUSE; INFLAMMATION; ASSOCIATION; PRUDENT; MODELS; AGE Objective: To explore the association between three previously identified and validated dietary patterns (Western, Prudent and Mediterranean) and breast cancer risk by tumour subtype and menopausal status. Methods: Data from the Spanish cohort of the European Prospective Investigation into Cancer and Nutrition study provided epidemiological information (including diet and cancer incidence) from 24,892 women (639 breast cancer cases) recruited between 1992 and 1996. The associations between adherence to the three dietary patterns and breast cancer risk (overall and by tumour subtype) were explored by fitting multivariate Cox proportional hazards regression models stratified by region, among other variables. A possible interaction with menopausal status (changing over time) was explored. Results: No clear association of the Prudent and Mediterranean dietary patterns with breast cancer risk was found. When compared with women with a level of adherence to the Western diet in the first quartile, women with a level of adherence in the third (hazard ratio (95 % confidence interval) (HR(95%CI)):1.37 (1.07;1.77)) and fourth quartiles (1.37 (1.03;1.83)); p for curvature of splines = 0.016) showed a non-linear increased risk, especially postmenopausal women (HR (95 % CI) 1.30 (0.98;1.72) in the third and 1.42 (1.04;1.94) in the fourth quartiles; p for curvature of splines = 0.081) and for estrogen or progesterone receptor positive with human epidermal growth factor receptor 2 negative tumours (HR (95 % CI) 1.62 (1.10;2.38) and 1.71 (1.11;2.63) for the third and fourth quartiles respectively; p for curvature of splines = 0.013). Conclusions: Intake of foods such as high-fat dairy products, red and processed meats, refined grains, sweets, caloric drinks, convenience food and sauces might be associated with a higher risk of breast cancer. Diet quality and cardiometabolic health in breast
cancer survivors: the Pathways Study BREAST CANCER RESEARCH AND
TREATMENT English Article

Breast cancer; Diet quality; Hypertension; Diabetes;
Dyslipidemia CORONARY-HEART-DISEASE; FAT VEGAN DIET;
SCIENTIFIC STATEMENT; COMPETING RISKS; BLOOD-PRESSURE; PREVENTION;
MORTALITY; ASSOCIATION; MANAGEMENT; ADHERENCE Purpose Breast
cancer (BC) survivors experience higher rates of cardiometabolic
conditions, partly due to treatment. While healthy eating
decreases the risk of these conditions in the general population,
its association in BC survivors is unclear. Methods We included
3415 participants from the Pathways Study, a prospective cohort of
women diagnosed with invasive BC between 2005 and 2013 and
followed through 2021. Concordance of food intakes from food
frequency questionnaires was estimated for five healthy eating
patterns at BC diagnosis: Dietary Approaches to Stop Hypertension
(DASH), healthy Plant-based Dietary Index (hPDI), 2020 Healthy
Eating Index (HEI), American Cancer Society nutrition guidelines
(ACS), and the alternate Mediterranean Diet Index (aMED). Incident
hypertension, diabetes, and dyslipidemia were identified through
electronic health records. Cumulative incidence rates (CIRs) were
estimated accounting for the competing risk of death. Covariate-
adjusted hazard ratios (HRs) and 95% confidence intervals (CIs)
were calculated using Fine and Gray regression models, stratified
by BC treatment status. Results Over an average 11.5 years (range
= 0.3-16.3) of follow-up, 554 (16.2%) participants developed
hypertension, 362 (10.6%) developed diabetes, and 652 (19.1%)
developed dyslipidemia. CIRs for any cardiometabolic condition 15
years after BC diagnosis were 39.2% for women in the highest HEI
quartile compared to 49.3% in the lowest. After adjustment, women
in the highest HEI quartile had lower risks of any cardiometabolic
condition (HR = 0.70, 95% CI 0.54-0.91, P-trend = 0.006),
including hypertension (HR = 0.71, 95% CI 0.54-0.94, P-trend =
0.007), diabetes (HR = 0.57, 95% CI 0.41-0.79, P-trend < 0.001),
and dyslipidemia (HR = 0.77, 95% CI 0.59-0.99, P-trend = 0.04).
Similar associations were observed for DASH, hPDI, and ACS with

diabetes incidence. Conclusion Healthier diets at BC diagnosis, particularly those aligned with the HEI, were associated with lower cardiometabolic risks.[Ergas, Isaac J.; Roh, Janise M.; Iribarren, Carlos; Nguyen-Huynh, Mai; Rana, Jamal S.; Laurent, Cecile A.; Lee, Valerie S.; Quesenberry, Charles P.; Bhatt, Ankeet; Kushi, Lawrence H.; Kwan, Marilyn L.] Kaiser Permanente Northern Calif, Div Res, 4480 Hacienda Dr, Pleasanton, CA 94558 USA; [Cheng, Richard K.; Greenlee, Heather] Univ Washington, Sch Med, Seattle, WA USA; [Kresovich, Jacob K.] H Lee Moffitt Canc Ctr & Res Inst, Tampa, FL USA; [Rana, Jamal S.] Kaiser Permanente Northern Calif, Oakland Med Ctr, Oakland, CA USA; [Rillamas-Sun, Eileen; Greenlee, Heather] Fred Hutchinson Canc Ctr, Div Publ Hlth Sci, Seattle, WA USA; [Bhatt, Ankeet] Stanford Univ, Sch Med, Div Cardiovasc Med, Palo Alto, CA USA; [Yao, Song] Roswell Pk Comprehens Canc Ctr, Dept Canc Prevent & Control, Buffalo, NY USA Kaiser Permanente; University of Washington; University of Washington Seattle; H Lee Moffitt Cancer Center & Research Institute; Kaiser Permanente; Fred Hutchinson Cancer Center; Stanford University; Roswell Park Comprehensive Cancer Center

Global, regional, and national burden of cervical cancer for 195 countries and territories, 2007-2017: findings from the Global Burden of Disease Study 2017BMC WOMENS HEALTH

English Article Global
Burden of Disease; Cervical cancer; Human papillomavirus;
Incidence; Disability-adjusted life-years; Death SUB-SAHARAN
AFRICA; HUMAN-PAPILLOMAVIRUS VACCINATION; SYSTEMATIC ANALYSIS;
SEXUAL-BEHAVIOR; NORTH-AFRICA; MIDDLE-EAST; MORTALITY; WOMEN;
EPIDEMIOLOGY; INFECTIONS Background Cervical cancer is one of
the most common cancers among women worldwide. The formulation or
evaluation on prevention strategies all require an accurate
understanding of the burden for cervical cancer burden. We aimed
to report the up-to-date estimates of cervical cancer burden at
global, regional, and national levels. Methods Data were extracted
from the Global Burden of Diseases, Injuries, and Risk Factors
Study (GBD) 2017 study. The counts, age-standardized rates, and
percentage changes of incidence, disability-adjusted life-years
(DALYs), and death attributed to cervical cancer at the global,
regional, and national levels in all 195 countries and territories

from 21 regions during 2007 to 2017 by age and by Socio-demographic Index (SDI) were measured. All estimates were reported with 95% uncertainty intervals (UIs). Results In 2017, 601,186 (95% UI 554,455 to 625,402) incident cases of cervical cancer were reported worldwide, which caused 8,061,667 (7,527,014 to 8,401,647) DALYs and 259,671 (241,128 to 269,214) deaths. The age-standardized rates for incidence, DALYs and death decreased by - 2.8% (- 7.8% to 0.6%), - 7.1% [- 11.8% to - 3.9%] and - 6.9% [- 11.5% to - 3.7%] from 2007 to 2017, respectively. The highest age-standardized incidence, DALYs and death rates in 2017 were observed in the low SDI quintile, Oceania, Central and Eastern Sub-Saharan Africa. During 2007 to 2017, only East Asia showed increase in these rates despite not significant. At the national level, the highest age-standardized rates for incidence, DALYs, and death in 2017 were observed in Kiribati, Somalia, Eritrea, and Central African Republic; and Georgia showed the largest increases in all these rates during 2007 to 2017. Conclusion Although the age-standardized rates for incidence, DALYs, and death of cervical cancer have decreased in most parts of the world from 2007 to 2017, cervical cancer remains a major public health concern in view of the absolute number of cervical cancer cases, DALYs, and deaths increased during this period. The challenge is more prone to in the low SDI quintile, Oceania, Central and Eastern Sub-Saharan Africa, East Asia, and some countries, suggesting an urgent to promote human papillomavirus vaccination in these regions. Interregional mechanisms for protection of african migrants in the Gulf Region: What prospects for Africa? OASIS-OBSERVATORIO DE ANALISIS DE LOS SISTEMAS INTERNACIONALES
English Article

interregionalism; intra-African migration; multilateral forum; policy consultation and coordination INTERNATIONAL MIGRATION Migration is a common phenomenon in Africa as citizens migrate within the continent for several reasons including education, family, employment, trade, and investment. Significant numbers of African migrants travel to the Middle East in search of economic opportunities. With the intensification of globalisation and the advancement of technology, human mobility across international borders is expected to rise in the coming decades. Despite challenges of international migration, migrants play a significant role in destination countries as they boost working-age population; contribute to revenue generation through taxes; contribute to human capital development; and enrich technological progress. Countries of origin increasingly appreciate their Diaspora communities due to remittances and migrants' skills. The growing number of African migrants calls for a strategic partnership between Africa and the Middle East through a multilateral forum that will enhance policy consultation and coordination for the benefit for both sides. The paper analyses intra-African migration, migration patterns from Africa to the Middle East and Gulf Cooperation Council (GCC) countries, drivers of migrations, migrants' positive contributions and challenges; national and Africa's Regional Economic Communities (RECs) responses in protecting the migrants. Key recommendations including the strengthening of free movement policies is critical Africa in ensuring that rights of African migrants are protected within Africa; working towards improving migration data to inform policy; enhancing interregional cooperation between Africa's RECs to enhancing the potential of intra-African migration; and fast-tracking the establishment of an effective multilateral forum for Africa and the Middle East for enhancing policy consultation and coordination to guarantee their common interests. Assessment of
 diagnosis of inflammatory breast cancer cases at two cancer
 centers in Egypt and Tunisia
 CANCER MEDICINE English

Article Edema; Egypt;
 erythema; inflammatory breast cancer; peau d'orange; Tunisia

The diagnosis of inflammatory breast cancer (IBC) is largely clinical and therefore inherently somewhat subjective. The objective of this study was to evaluate the diagnosis of IBC at two centers in North Africa where a higher proportion of breast cancer is diagnosed as IBC than in the United States (U.S.). Physicians prospectively enrolled suspected IBC cases at the National Cancer Institute (NCI) - Cairo, Egypt, and the Institut Salah Azaiz (ISA), Tunisia, recorded extent and duration of signs/symptoms of IBC on standardized forms, and took digital photographs of the breast. After second-level review at study hospitals, photographs and clinical information for confirmed IBC cases were reviewed by two U.S. oncologists. We calculated percent agreement between study hospital and U.S. oncologist diagnoses. Among cases confirmed by at least one U.S. oncologist, we calculated median extent and duration of signs and Spearman correlations. At least one U.S. oncologist confirmed the IBC diagnosis for 69% (39/50) of cases with photographs at the NCI-Cairo and 88% (21/24) of cases at the ISA. All confirmed cases had at least one sign of IBC (erythema, edema, peau d'orange) that covered at least one-third of the breast. The median duration of signs ranged from 1 to 3 months; extent and duration of signs were not statistically significantly correlated. From the above-mentioned outcomes, it can be concluded that the diagnosis of a substantial proportion of IBC cases is unambiguous, but a subset is difficult to distinguish from other types of locally advanced breast cancer. Among confirmed cases, the extent of signs was not related to delay in diagnosis. GEICAM Researchers Evaluating the Applicability of Data-Driven Dietary Patterns to Independent Samples with a Focus on Measurement Tools for Pattern Similarity JOURNAL OF THE ACADEMY OF NUTRITION AND DIETETICS English

Article

Dietary patterns;

Pattern similarity; Congruence coefficient; Breast cancer;

Mediterranean/Western patterns FOOD-FREQUENCY QUESTIONNAIRE;

BREAST-CANCER RISK; PLASMA-CONCENTRATIONS; POSTMENOPAUSAL WOMEN;

MULTIPLE IMPUTATION; RELATIVE VALIDITY; CHRONIC DISEASE; SWEDISH

WOMEN; QUALITY; REPRODUCIBILITY Background Diet is a key

modifiable risk for many chronic diseases, but it remains unclear whether dietary patterns from one study sample are generalizable to other independent populations. Objective The primary objective of this study was to assess whether data-driven dietary patterns from one study sample are applicable to other populations. The secondary objective was to assess the validity of two criteria of pattern similarity. Methods Six dietary patterns-Western (n = 3), Mediterranean, Prudent, and Healthyfrom three published studies on breast cancer were reconstructed in a case-control study of 973 breast cancer patients and 973 controls. Three more internal patterns (Western, Prudent, and Mediterranean) were derived from this case-control study's own data. Statistical analysis Applicability was assessed by comparing the six reconstructed patterns with the three internal dietary patterns, using the congruence coefficient (CC) between pattern loadings. In cases where any pair met either of two commonly used criteria for declaring patterns similar (CC $\geq$ 0.85 or a statistically significant [$P < 0.05$] Pearson correlation), then the true similarity of those two dietary patterns was doublechecked by comparing their associations to risk for breast cancer, to assess whether those two criteria of similarity are actually reliable. Results Five of the six reconstructed dietary patterns showed high congruence (CC > 0.9) to their corresponding dietary pattern derived from the case-control study's data. Similar associations with risk for breast cancer were found in all pairs of dietary patterns that had high CC but not in all pairs of dietary patterns with statistically significant correlations. Conclusions Similar dietary patterns can be found in independent samples. The P value of a correlation coefficient is less reliable than the CC as a criterion for declaring two dietary patterns similar. This study shows that diet scores based on a particular study are generalizable to other populations.

Triple negative breast cancer in North of Morocco:
clinicopathologic and prognostic features BMC WOMENS HEALTH
English Article

Triple negative breast cancer; BRCA1; BRCA2; Prognostic; Clinicopathologic; Survival analysis ESTROGEN-RECEPTOR; WOMEN; SURVIVAL; BRCA1; PREVALENCE; RECURRENCE; MUTATIONS; PATTERNS; CARCINOMAS; RACE Background: Triple Negative Breast Cancer (TNBC) is defined by a lack of estrogen and progesterone receptor gene expression and by the absence of overexpression on HER2. It is associated to a poor prognosis. We propose to analyze the clinicopathologic and prognostic characteristics of this breast cancer subtype in a Mediterranean population originated or resident in the North of Morocco. Methods: We conducted a retrospective study of 279 patients diagnosed with breast cancer between January 2010 and January 2015. Clinicopathologic and prognostic features have been analyzed. Disease-Free Survival (DFS) and Overall Survival (OS) have been estimated. Results: Of all cases, forty-nine (17.6 %) were identified as having triple negative breast cancer with a median age of 46 years. The average tumor size was 3.6 cm. The majority of patients have had invasive ductal carcinoma (91.8 %) and 40.4 % of them were grade III SBR. Nodal metastasis was detected in 38.9 % of the patients and vascular invasion was found in 36.6 % of them. About half of the patients had an early disease (53.1 %) and 46.9 % were diagnosed at an advanced stage. Patients with operable tumors (61.2 %) underwent primary surgery and adjuvant chemotherapy. Patients with no operable tumors (26.5 %) received neoadjuvant chemotherapy followed by surgery, and patients with metastatic disease (12.2 %) were treated by palliative chemotherapy. DFS and OS at 5 years were respectively 83.7 and 71.4 %. Among 49, twelve had recurrences, found either when diagnosing them or after a follow-up. Local relapse was 6.1 %. Lung and liver metastases accounted consecutively for 8.2 and 10.2 %. Bone metastases were found in 4.1 % and brain metastases in 2.1 % of the cases. Conclusion: Our results are in accordance with literature data, particularly what concerning young age and poor prognosis among TNBC phenotype. Therefore, the identification of BRCA mutations in our population seems to be essential in order to better adapt management options for this aggressive form of breast cancer. Elaeagnus angustifolia Plant Extract Inhibits Epithelial-Mesenchymal Transition and Induces Apoptosis via HER2 Inactivation and JNK Pathway in HER2-Positive Breast Cancer Cells MOLECULES

English Article Elaeagnus angustifolia; breast cancer; EMT; chemoprevention; apoptosis TRAIL-INDUCED APOPTOSIS; C-JUN; SIGNAL-TRANSDUCTION; DEPENDENT DEGRADATION; LIVER-CANCER; BCL-2; PHOSPHORYLATION; ACTIVATION; L.; PREVENTION Elaeagnus angustifolia (EA) is a medicinal plant used for treating several human diseases in the Middle East. Meanwhile, the outcome of EA extract on HER2-positive breast cancer remains nascent. Thus, we herein investigated the effects of the aqueous EA extract obtained from the flowers of EA on two HER2-positive breast cancer cell lines, SKBR3 and ZR75-1. Our data revealed that EA extract inhibits cell proliferation and deregulates cell-cycle progression of these two cancer cell lines. EA extract also prevents the progression of epithelial-mesenchymal transition (EMT), an important event for cancer invasion and metastasis; this is accompanied by upregulations of E-cadherin and beta-catenin, in addition to downregulations of vimentin and fascin, which are major markers of EMT. Thus, EA extract causes a drastic decrease in cell invasion ability of SKBR3 and ZR75-1 cancer cells. Additionally, we found that EA extract inhibits colony formation of both cell lines in comparison with their matched control. The molecular pathway analysis of HER2 and JNK1/2/3 of EA extract exposed cells revealed that it can block HER2 and JNK1/2/3 activities, which could be the major molecular pathway behind these events. Our findings implicate that EA extract may possess chemo-preventive effects against HER2-positive breast cancer via HER2 inactivation and specifically JNK1/2/3 signaling pathways. COLORECTAL CANCER: AN UPDATE ON THE EFFECTS OF
LYCOPENE ON TUMOR PROGRESSION AND CELL PROLIFERATION JOURNAL
OF BIOLOGICAL REGULATORS AND HOMEOSTATIC AGENTS

English Article

colorectal cancer; lycopene; oxidative stress; tomato;
antioxidant; proliferation; progressionMOUSE XENOGRAFT MODEL;
COLON-CANCER; GROWTH; CAROTENOIDS; INHIBITION; SUPPRESSION;
CONSUMPTION; PATHWAY Colorectal cancer (CRC) is one of the most
common cancers worldwide. Various factors, including oxidative
stress, where excessive productions of reactive oxygen species
(ROS) and reactive nitrogen species (RNS) occur, contribute to its
pathogenesis. Numerous studies have investigated the effect of
antioxidant substances derived from food such as fruits and
vegetables; however, data on Lycopene are still rare. Studies on
HT-29 colorectal cancer cells and on animal models have shown that
lycopene has effects on cell proliferation and on the progression
of the CRC by interacting with various cellular signaling
pathways. This analysis of the literature focused on the
antioxidant effect of lycopene, a substance that is found in the
tomato. [Carini, F.; David, S.; Tomasello, G.; Mazzola, M.;

Dietary Fat Intake: Associations with Dietary Patterns and Postmenopausal Breast Cancer-A Case-Control Study
CANCERS English Article

breast cancer; fat intake; dietary pattern; Mediterranean diet; women MEDITERRANEAN DIET; OLIVE OIL; RISK; HEALTH; MORTALITY; METAANALYSIS; HABITS; COHORT; ACIDS The aim of this study was to assess the associations of dietary fat intake with BC occurrence and dietary patterns. This case-control study involved 420 women aged 40-79 years from northeastern Poland, including 190 newly diagnosed BC cases. Dietary data were collected using a food frequency questionnaire (62-item FFQ-6 (R)). The Quick Food Scan of the National Cancer Institute and the Percentage Energy from Fat Screener scoring procedures were used to estimate the percentage energy from dietary fat (Pfat). The odds of BC occurrence was three times higher in the Pfat > 32%. The Pfat > 32% was positively associated with the 'Non-Healthy' DP and inversely associated with the Polish-aMED (R) score, 'Prudent' DP, and 'Margarine and Sweetened Dairy' DP. This case-control study suggests that a higher dietary fat intake (>32%) may contribute to an increased occurrence of peri- and postmenopausal breast cancer in women. Given the obtained results, an unhealthy dietary pattern characterized by the consumption of highly processed, high in sugar foods and animal fat foods should be avoided to reduce fat intake. Instead, the frequent consumption of low-processed plant foods, fish, and moderate consumption of low-fat dairy should be recommended since this pro-healthy diet is inversely associated with dietary fat intake. A genome wide SNP genotyping study in the Tunisian population: specific reporting on a subset of common breast cancer risk loci BMC CANCER English

Article Breast cancer susceptibility; Haplotype analysis; Population genetics; Functional analysis SUSCEPTIBILITY LOCI; CONFER SUSCEPTIBILITY; HEREDITARY BREAST; GENETIC-STRUCTURE; AFRICAN-AMERICAN; R-PACKAGE; ASSOCIATION; MUTATIONS; VARIANTS; BRCA1BackgroundBreast cancer is the most common cancer in women worldwide. Around 50% of breast cancer familial risk has been so far explained by known susceptibility alleles with variable levels of risk and prevalence. The vast majority of these breast cancer associated variations reported to date are from populations of European ancestry. In spite of its heterogeneity and genetic wealth, North-African populations have not been studied by the HapMap and the 1000Genomes projects. Thus, very little is known about the genetic architecture of these populations.MethodsThis study aimed to investigate a subset of common breast cancer loci in the general Tunisian population and to compare their genetic composition to those of other ethnic groups. We undertook a genome-wide haplotype study by genotyping 135 Tunisian subjects using the Affymetrix 6.0-Array. We compared Tunisian allele frequencies and linkage disequilibrium patterns to those of HapMap populations and we performed a comprehensive assessment of the functional effects of several selected variants.ResultsHaplotype analyses showed that at

risk haplotypes on 2p24, 4q21, 6q25, 9q31, 10q26, 11p15, 11q13 and 14q32 loci are considerably frequent in the Tunisian population (>20%). Allele frequency comparison showed that the frequency of rs13329835 is significantly different between Tunisian and all other HapMap populations. LD-blocks and Principle Component Analysis revealed that the genetic characteristics of breast cancer variants in the Tunisian, and so probably the North-African populations, are more similar to those of Europeans than Africans. Using eQTL analysis, we characterized rs9911630 as the most strongly expression-associated SNP that seems to affect the expression levels of BRCA1 and two long non coding RNAs (NBR2 and LINC008854). Additional in-silico analysis also suggested a potential functional significance of this variant. Conclusions We illustrated the utility of combining haplotype analysis in diverse ethnic groups with functional analysis to explore breast cancer genetic architecture in Tunisia. Results presented in this study provide the first report on a large number of common breast cancer genetic polymorphisms in the Tunisian population which may establish a baseline database to guide future association studies in North Africa. HPV Types and Variants Among Cervical Cancer Tumors in Three Regions of Tunisia JOURNAL OF MEDICAL VIROLOGY English Article

North Africa; Cancer Registry; human papillomavirus (HPV); HPV variants; HPV16 HUMAN-PAPILLOMAVIRUS TYPE-16; INTRAEPITHELIAL NEOPLASIA; MOLECULAR VARIANTS; WOMEN; POPULATION; RISK; PREVALENCE; GENOTYPES; LINEAGES; LESIONS Cervical cancer is the second most common cancer among Tunisian women, and the incidence rates vary by region. Three Tunisian registries report age-standardized rates of 6.3/10(5) in the central region, 5.4/10(5) in the north, and 2.7/10(5) in the south. High-risk human papillomavirus (HPV) types and their variants differ in carcinogenic potential and geographic distribution. The HPV type and variant distribution could be a factor in the differing rates between regions of Tunisia. Tumor tissue was collected from 142 Tunisian cervical cancer patients. Demographic and reproductive characteristics of the patients were abstracted from cancer registry and hospital records. HPV type and variant analyses were performed using PCR-based Luminex and dot-blot hybridization assays. Eighty-three percent of tumors were infected with at least one HPV type. European variants of HPV16/18 were the most prevalent in tumors from all three regions, with all HPV18 infections and 64% of HPV16 infections being of European lineage. A higher frequency of HPV16 was present in Northern Tunisia (80%) than in Central (68%) or Southern Tunisia (50%) ($P = 0.02$). HPV18/45 was significantly more common in adenocarcinomas (50%) than in squamous cell carcinomas (11%) ($P = 0.004$). Frequent infection with European HPV variants most likely reflects the history of European migration to Tunisia. In addition to the importance of understanding the variants of HPV in Tunisia, behavioral and cultural attitudes towards screening and age-specific infection rates should be investigated to aid the development of future vaccination and HPV screening programs and policies. Diet Quality and Colorectal Cancer Risk in the Women's Health Initiative Observational Study AMERICAN JOURNAL OF EPIDEMIOLOGY
English Article

Alternative Healthy Eating Index; Alternative Mediterranean Diet; colorectal cancer; diet; diet quality; Dietary Approaches to Stop Hypertension; dietary patterns; Healthy Eating Index
CORONARY-HEART-DISEASE; POSTMENOPAUSAL WOMEN; INFLAMMATORY INDEX; MORTALITY; PATTERNS; ASSOCIATION; SMOKING; STROKE; SCORES; FOOD Diet quality index scores on Healthy Eating Index 2010 (HEI-2010), Alternative HEI-2010, alternative Mediterranean Diet Index, and the Dietary Approaches to Stop Hypertension (DASH) index have been inversely associated with all-cause and cancer-specific death. This study assessed the association between these scores and colorectal cancer (CRC) incidence as well as CRC-specific mortality in the Women's Health Initiative Observational Study (1993-2012), a US study of postmenopausal women. During an average of 12.4 years of follow-up, there were 938 cases of CRC and 238 CRC-specific deaths. We estimated multivariate hazard ratios and 95% confidence intervals for relationships between quintiles of diet scores (from baseline food frequency questionnaires) and outcomes. HEI-2010 score (hazard ratios were 0.81, 0.77, and 0.73 with italic toggle="yes" P values of 0.04, 0.01, and < 0.01 for quintiles 3-5 vs. quintile 1, respectively) and DASH score (hazard ratios were 0.72, 0.74, and 0.78 with italic toggle="yes" P values of < 0.01, < 0.01, and 0.03 for quintiles 3-5 vs. quintile 1, respectively), but not other diet scores, were associated with a lower risk of CRC in adjusted models. No diet scores were

significantly associated with CRC-specific mortality. Closer adherence to HEI-2010 and DASH dietary recommendations was inversely associated with risk of CRC in this large cohort of postmenopausal women. Relationship between social determinants of health and
quality of life in low income adults with diabetes in Lebanon
POSTGRADUATE MEDICINE English Article

Type 2 diabetes; social determinants
of health; quality of life; MENA region; Lebanon ADVERSE
CHILDHOOD EXPERIENCES; DEPRESSION; IMPACT; VALIDATION; OUTCOMES;
ANXIETY; RISK; COMPLICATIONS; QUESTIONNAIRE; VALIDITY

Background & objectiveGlobal rates of type 2 diabetes (T2DM)
are increasing, with the Middle East and North Africa (MENA)
region having the second highest prevalence in the world.
Populations from the MENA region, including Lebanon, are also
witnessing massive waves of immigration to the western hemisphere.
Limited data exist about how social determinants of health (SDOH)
impact outcomes for T2DM in this population. Thus, the aim of this
study was to assess the relationship between SDOH and quality of
life (QoL) in Lebanese adults with T2DM. MethodsAdults with T2DM (n
= 300) were recruited from primary healthcare centers in Lebanon.
Demographic characteristics and WHO QoL domains (physical health,
psychological wellbeing, social relationships, and environment)
were assessed. SDOH included socioeconomic, neighborhood/built
environment, and psychosocial variables. Partially and fully
adjusted regression models were used to test for associations
between SDOH and QoL domains. ResultsMean age of the participants
was 60.3 years, 48% were women, 73% were married, and 64% had less
than high-school education. Results from the fully adjusted
regression models showed that psychosocial (i.e. adverse childhood
experiences and depression), socioeconomic (i.e. employment,
income, family size, insurance, financial status, and financial
independence), and neighborhood/built environment (i.e.
transportation, number of rooms in the household, and certain
household items) variables were independent correlates of
different QoL domains. ConclusionsThis study shows that
psychosocial, socioeconomic, and neighborhood/built environment
variables are differentially associated with different QoL
domains, suggesting that SDOH factors are strongly associated with
quality of life in low-income adults with T2DM in Lebanon.

micronutrient intake in colorectal cancer patients with tumors
presenting promoter hypermethylation in p16^{INK4a},
p14^{ARF} and hMLH1 ANTICANCER RESEARCH
English Article DNA
hypermethylation; colorectal cancer; micronutrients; folate;
vitamin CPG ISLAND METHYLATION; DNA METHYLATION;
METHYLENETETRAHYDROFOLATE REDUCTASE; DEPENDENT RISK; FOLATE; GENE;
HYPOMETHYLATION; SUSCEPTIBILITY; ASSOCIATION; EXPRESSION
Background: The diversity of the Mediterranean diet and the
heterogeneity of acquired epigenetic alterations in colorectal
cancer (CRC) led us to examine the possible association between
dietary factors and promoter hypermethylation in genes implicated
in the pathogenesis of these neoplasms (p16(INK4a), p14(ARF),
hMLH1) and the interaction with methylene tetrahydrofolate
reductase (MTHFR) C677T polymorphism. Patients and Methods: For
the molecular study, 120 CRC patients were analyzed for hMLH1
promoter methylation status and MTHFR genotyping. Dietary patterns
and molecular data on p16(INK4a) and p14(ARF) methylation were
obtained from previous studies with this populations. Results:
Patients with methylation in p16(INK4a) consumed significantly
less folate (p=0.01), vitamin A (p=0.01), vitamin B1 (p=0.007),
potassium (p=0.03) and iron (p=0.02) than controls. Patients with
methylation in p14(ARF) or hMLH1 consumed significantly less
vitamin A (p=0.001 and p=0.05, respectively). Conclusion: These
results support that certain micronutrients protect against
colorectal neoplasia and emphasize the importance of considering
the different molecular forms of CRC as etiologically distinct
diseases. Univ Barcelona, Sch Med, Dept Pharmacol, IDIBAPS, E-

Deregulated expression of cryptochrome genes in human colorectal cancer MOLECULAR CANCER English
 Article Clock gene;

Cryptochrome; p53; Colorectal cancer; Chronotherapy; Circadian CIRCADIAN TIMING SYSTEM; CLOCK GENES; CHEMOTHERAPY; SEX; RHYTHMS; ORGANIZATION; OXALIPLATIN; SENSITIVITY; DISRUPTION; MACHINERY Background: Circadian disruption and deranged molecular clockworks are involved in carcinogenesis. The cryptochrome genes (CRY1 and CRY2) encode circadian proteins important for the functioning of biological oscillators. Their expression in human colorectal cancer (CRC) and in colon cancer cell lines has not been evaluated so far. Methods: We investigated CRY1 and CRY2 expression in fifty CRCs and in the CaCo2, HCT116, HT29, SW480 cell lines. Results: CRY1 ($p = 0.01$) and CRY2 ($p < 0.0001$) expression was significantly changed in tumour tissue, as confirmed in a large independent CRC dataset. In addition, lower CRY1 mRNA levels were observed in patients in the age range of 6274 years ($p = 0.018$), in female patients ($p = 0.003$) and in cancers located at the transverse colon ($p = 0.008$). Lower CRY2 levels were also associated with cancer location at the transverse colon ($p = 0.007$). CRC patients displaying CRY1 ($p = 0.042$) and CRY2 ($p = 0.043$) expression levels over the median were hallmarked by a poorer survival rate. Survey of selected colon cancer cell lines evidenced variable levels of cryptochrome genes expression and time-dependent changes in their mRNA levels. Moreover, they showed reduced apoptosis, increased proliferation and different response to 5-fluorouracil and oxaliplatin upon CRY1 and CRY2 ectopic expression. The relationship with p53 status came out as an additional layer of regulation: higher CRY1 and CRY2 protein levels coincided with a wild type p53 as in HCT116 cells and this condition only marginally affected the apoptotic and cell proliferation characteristics of the cells upon CRY ectopic expression. Conversely, lower CRY and CRY2 levels as in HT29 and SW480 cells coincided with a mutated p53 and a more robust apoptosis and proliferation upon CRY transfection. Besides, an heterogeneous pattern of ARNTL, WEE and c-MYC expression hallmarked the chosen colon cancer cell lines and likely influenced their phenotypic changes. Conclusion: Cryptochrome gene expression is altered in CRC, particularly in elderly subjects, female patients and cancers located at the transverse colon, affecting overall survival. Altered CRY1 and CRY2 expression

patterns and the interplay with the genetic landscape in colon cancer cells may underlie phenotypic divergence that could influence disease behavior as well as CRC patients survival and response to chemotherapy. POSITIVE Interrupting Endocrine Therapy to Attempt Pregnancy after Breast Cancer NEW ENGLAND JOURNAL OF MEDICINE

English Article

YOUNG-WOMEN; FERTILITY; PRESERVATION; ISSUES Background
Prospective data on the risk of recurrence among women with

hormone receptor-positive early breast cancer who temporarily discontinue endocrine therapy to attempt pregnancy are lacking.

Methods We conducted a single-group trial in which we evaluated the temporary interruption of adjuvant endocrine therapy to attempt pregnancy in young women with previous breast cancer. Eligible women were 42 years of age or younger; had had stage I, II, or III disease; had received adjuvant endocrine therapy for 18 to 30 months; and desired pregnancy. The primary end point was the number of breast cancer events (defined as local, regional, or distant recurrence of invasive breast cancer or new contralateral invasive breast cancer) during follow-up. The primary analysis was planned to be performed after 1600 patient-years of follow-up. The prespecified safety threshold was the occurrence of 46 breast cancer events during this period. Breast cancer outcomes in this treatment-interruption group were compared with those in an external control cohort consisting of women who would have met the entry criteria for the current trial.

Results Among 516 women, the median age was 37 years, the median time from breast cancer diagnosis to enrollment was 29 months, and 93.4% had stage I or II disease. Among 497 women who were followed for pregnancy status, 368 (74.0%) had at least one pregnancy and 317 (63.8%) had at least one live birth. In total, 365 babies were born. At 1638 patient-years of follow-up (median follow-up, 41 months), 44 patients had a breast cancer event, a result that did not exceed the safety threshold. The 3-year incidence of breast cancer events was 8.9% (95% confidence interval [CI], 6.3 to 11.6) in the treatment-interruption group and 9.2% (95% CI, 7.6 to 10.8) in the control cohort.

Conclusions Among select women with previous hormone receptor-positive early breast cancer, temporary interruption of endocrine therapy to attempt pregnancy did not confer a greater short-term risk of breast cancer events, including distant recurrence, than that in the external control cohort. Further follow-up is critical to inform longer-term safety. (Funded by ETOP IBCSG Partners Foundation and others; POSITIVE ClinicalTrials.gov number, NCT02308085.)

Interrupting Therapy to Attempt Pregnancy after Breast Cancer In women with previous breast cancer who temporarily discontinued adjuvant endocrine therapy to attempt pregnancy, the frequency of breast cancer events was below the prespecified safety threshold and similar to that in controls.

Mediterranean diet improves liver health but does not
protect against azoxymethane-induced colon tumorigenesis compared
to Western diet in A/J mice EXPERIMENTAL AND MOLECULAR PATHOLOGY
English Article

Azoxymethane; Mediterranean diet; Colorectal cancer; Non-
alcoholic fatty liver disease (NAFLD) COLORECTAL-CANCER;
METABOLIC-ACTIVATION; CARCINOGENESIS; INFLAMMATION; CYP2E1;
METHYLAZOXYMETHANOL; EXPRESSION; EXTRACTS; MODEL; RISK

Introduction: Abundant evidence indicates that the
Mediterranean (MED) diet pattern is beneficial for health,
especially cardiovascular health. Epidemiological evidence
indicates that the MED diet also affords protection against
colorectal cancer (CRC). To date, preclinical models have only
evaluated specific MED diet components and therefore, although
supportive, fall short of confirming the chemoprotective capacity
of this complex dietary pattern. We sought to address this gap.
Method: A/J mice were randomized to receive Western (WRN) or MED
diets differing in their fat, protein, and carbohydrate sources.
Azoxymethane (AOM) was used to initiate colon tumorigenesis and
mice were maintained for 19 weeks after the final dose. Result:
Unexpectedly high mortality was observed amongst male mice
following the second AOM dose. At the end of the study hepatic
Cyp2E1, an enzyme that metabolize AOM, was lower in males than
females. Livers from MED diet mice were significantly lighter, had
lower histologic Non-Alcoholic Fatty Liver Disease (NAFLD) scores,

and contained less triglycerides than WRN mice. Amongst females, serum alanine transaminase (ALT) was also lower in MED than WRN mice. Amongst male mice, those fed MED diet presented with significantly more colonic tumors than those on the WRN diet. Conclusion: In this study male mice displayed elevated sensitivity to AOM-induced hepatotoxicity and mortality than females. In agreement with human and preclinical data, livers of MED-diet-fed mice were healthier than those fed WRN diets. We could not confirm the chemoprotective capacity of the MED diet. Additional studies are required to evaluate the purported anticancer effect of the MED diet.  Özçelik, B; Serin, IS; Gökahmetoglu, S;
 Basbug, M; Erez, R Human papillomavirus frequency
 of women at-low risk of developing cervical cancer:: a preliminary
 study from a Turkish university hospital EUROPEAN JOURNAL OF
 GYNAECOLOGICAL ONCOLOGY English Article
 HPV frequency; low-risk women; Middle
 East Anatolia HYBRID CAPTURE; INFECTION; PREVALENCE Purpose:
 To investigate the frequency of human papillomavirus (HPV)
 infection among low-risk women for cervical cancer in our region.
 Methods: In one year period, 230 consecutive women at low risk of
 developing cervical cancer were enrolled to the study. HPV DNA
 testing was performed by Hybrid Capture-I System (HC-I) and groups
 were constituted by HPV-positive and HPV-negative women. A
 comparison of the groups according to age, obstetric history and
 age at the beginning of sexual intercourse was made. Statistical
 analysis was performed. Results: The frequency rate of HPV
 infection was demonstrated to be 6.1% (n = 14) in our study (5.9%
 in women less than or equal to 45 years and 7.7% in women > 45
 years). Age-dependent differences were not observed between
 groups. There was no significant difference between HPV-positive
 and negative women regarding obstetric characteristics and mean
 age at first intercourse. Conclusion: This study provided
 significant information on the frequency of HPV infection of low-

risk women in our region. When considered with studies performed in other countries, our study may give some help on the natural history of HPV infection and cervical squamous lesions. Saliba, Walid; Rennert, Hedy S.; Gronich, Naomi; Gruber, Stephen B.; Rennert, Gad Red meat and
processed meat intake and risk of colorectal cancer: a population-
based case-control study EUROPEAN JOURNAL OF CANCER PREVENTION
English Article

beef; colorectal cancer; lamb; pork; processed meat; red
meat CONSUMPTION; ASSOCIATIONS To examine the association
between red meat subtypes intake and risk of colorectal cancer
(CRC) among Jewish and Arabs populations in a unique Mediterranean
environment. The Molecular Epidemiology of Colorectal Cancer study
(n=10 026) is a prospective population-based case-control study in
northern Israel. Participants were interviewed in-person about
their dietary intake and lifestyle using a questionnaire that
included a food-frequency questionnaire. Red meat consumption in
Israel was found to be especially low in the Jewish population
(1.29 +/- 1.45 servings/week), but higher in Arabs (3.0 +/- 1.98
servings/week) (P<0.001). Beef was the most commonly consumed red
meat by Jews (1.15/1.29 servings/week, 89%) and proportionally
less so by Arabs (2.00/3.00, 67%). Processed meat consumption
(mostly pork free) was lower among Arabs (0.9 +/- 1.56
servings/week) compared with Jews (1.97 +/- 2.97 servings/week)
(P<0.001). The adjusted odds of CRC per one serving/week of red
meat were 1.05 (95% confidence interval: 1.01-1.08) in Jews and
0.94 (0.88-1.01) in Arabs. Compared with no consumption, beef
consumption was associated with odds ratio (OR)=0.96 (0.86-1.07)
in Jews and 0.94 (0.61-1.45) in Arabs, lamb consumption with
OR=1.28 (1.10-1.5) and 1.01 (0.75-1.37), pork consumption with
OR=1.44 (1.24-1.67) and 1.07 (0.73-1.56), and processed meat
consumption with OR=1.22 (1.10-1.35) and 1.04 (0.82-1.33) in Jews
and Arabs, respectively. Overall red meat consumption was
associated weakly with CRC risk, significant only for lamb and
pork, but not for beef, irrespective of tumor location. Processed
meat was associated with mild CRC risk. [Saliba, Walid; Rennert,

Arezki Effect of dairy products intake on breast
cancer risk: A case-control study in Algeria NUTRITION CLINIQUE ET
METABOLISME English Article
Breast cancer; Dairy products; Diet; Epidemiology
GROWTH-FACTOR-I; MILK-PRODUCTS; VITAMIN-D; MEDITERRANEAN
DIET; CALCIUM INTAKE; FOOD; CONSUMPTION; NUTRITION; INSULIN; WOMEN
Objectives. The aim of this hospital-based case-control
study is to evaluate the association between dairy products
consumption and breast cancer risk. This relationship has not
previously been studied in Algeria. Materials and methods. Our
study was conducted on 184 breast cancer patients and equal number
of age-matched controls. Data on sociodemographic characteristics,
reproductive and menstrual history, medical history, lifestyle
factors and anthropometric measurements were collected by
interviewers. Dietary intake information was also obtained using a
short food questionnaire. The Odds ratios [95% confidence interval
(CI)] of breast cancer were estimated across categories of dairy
intake using multivariable logistic regression. Results. We
observed an increased breast cancer risk in women with higher
consumption of milk [OR = 2.61, 95% CI: 1.32-5.16, P = 0.027]
comparing with those in lower category of intake. An inverse
association with breast cancer risk was observed for total cheese
intake when comparing highest with lowest quartiles. The
protective effect of cheese was confirmed only for fresh cheese.
No significant association was found for other types of dairy
foods. Conclusion. Our study demonstrates the differential effect
of dairy products types on breast cancer risk. Future studies are
warranted to confirm these results. (C) 2018 Association pour le

Among 4 Diet Quality Indexes, Only the
Alternate Mediterranean Diet Score Is Associated with Better
Colorectal Cancer Survival and Only in African American Women in
the Multiethnic Cohort JOURNAL OF NUTRITION English

Article colorectal cancer;
nutrition; Healthy Eating Index; Alternative Healthy Eating Index;
alternate Mediterranean Diet score; Dietary Approaches to Stop
Hypertension index; dietary patterns; survival; Cox regression;
Multiethnic Cohort COLON-CANCER; POSTMENOPAUSAL WOMEN; RISK;
PATTERNS; MORTALITY; METAANALYSIS; ADHERENCE; DISEASE; WHITES;
ANTIOXIDANTS

Background: Colorectal cancer (CRC) is the second
leading cause of cancer-related death in the United States, with a
5-y survival rate of similar to 65%. Therefore, the identification
of modifiable health factors to improve CRC survival is crucial.
Objective: We investigated the association of 4 prediagnostic a
priori diet quality indexes with CRC-specific and all-cause
mortality in the Multiethnic Cohort (MEC). Methods: The MEC
included >215,000 African-American, Native Hawaiian, Japanese-
American, Latino, and white adults living in Hawaii and California
who completed a validated quantitative food-frequency
questionnaire in 1993-1996. CRC cases and deaths were identified
through linkages to cancer registries and to state and national
vital registries. Sex specific HRs and 95% CIs were estimated for

the Healthy Eating Index (HEI) 2010, the Alternative HEI (AHEI) 2010, the alternate Mediterranean Diet (aMED) score, and the Dietary Approaches to Stop Hypertension (DASH) index with CRC-specific and overall mortality as the primary outcomes. Ethnicity-specific analyses were the secondary outcomes. Results: Among 4204 MEC participants diagnosed with invasive CRC through 2010, 1976 all-cause and 1095 CRC-specific deaths were identified. A higher aMED score was associated with lower CRC-specific mortality in women [HR continuous pattern score divided by its respective SD (HR1SD): 0.86; 95% CI: 0.77, 0.96] but not in men (HR1SD: 1.01; 95% CI: 0.92, 1.11). A higher aMED score was also associated with lower all-cause mortality in women (HR1SD: 0.88; 95% CI: 0.81, 0.96) but not in men (HR1SD: 1.00; 95% CI: 0.93, 1.07). The HEI-2010, AHEI-2010, and DASH index were not significantly associated with CRC-specific or with all-cause mortality. The inverse relation for the aMED score was limited to African Americans and to colon (compared with rectal) cancer. Conclusions: The aMED score was related to lower mortality only in African-American women (1 of 5 ethnic groups studied). The results should be interpreted with caution due to the small numbers of cases within ethnic groups and the issue of multiple testing. colorectal cancer patients MEDICAL MICROBIOLOGY AND IMMUNOLOGY
English Article

Gut microbiome composition; Colorectal cancer; Bacterial
community; 16S rRNA sequencing; Moroccan population

BACTEROIDES-FRAGILIS; PERIODONTAL-DISEASE; INTESTINAL
MICROBIOTA; BACTERIAL METABOLITES; MEDITERRANEAN DIET; FECAL
MICROBIOTA; LIFE-STYLE; COLON; FUSOBACTERIUM; RISK Although
colorectal cancer is the third leading cause of death in Morocco,
there are no studies of the microbiome changes associated with the
disease in the Moroccan population. The aim of our study was to
compare the stool microbiome of Moroccan cancer patients with
healthy individuals. We analyzed the microbiome composition of
samples from 11 CRC patients and 12 healthy individuals by 16S
rRNA amplicon sequencing. Principal coordinate analysis of samples
revealed defined cancer versus healthy clusters. Our findings
showed that cancer samples had higher proportions of Firmicutes
($T=50.5\%$; $N=28.4\%$; $p=0.04$), specifically of Clostridia
($T=48.3\%$; $N=19.0\%$; $p=0.002$), and Fusobacteria ($T=0.1\%$; $N=0.0\%$;
 $p=0.02$), especially of Fusobacteriia ($T=0.1\%$; $N=0.0\%$; $p=0.02$),
while Bacteroidetes were enriched in healthy samples ($T=35.1\%$;
 $N=62.8\%$; $p=0.06$), particularly the class Bacteroidia ($T=35.1\%$;
 $N=62.6\%$; $p=0.06$). Porphyromonas, Clostridium, Ruminococcus,
Selenomonas, and Fusobacterium were significantly overrepresented
in diseased patients, similarly to other studies. Predicted
functional information showed that bacterial motility proteins,
flagellar assembly, and fatty acid biosynthesis metabolism were
significantly overrepresented in cancer patients, while amino acid
metabolism and glycan biosynthesis were overrepresented in
controls. This suggests that involvement of these functional
metagenomes is similar and relevant in the carcinogenesis process,
independent of the origin of the samples. Results from this study
allowed identification of bacterial taxa relevant to the Moroccan
population and encourages larger studies to facilitate population-
directed therapeutic approaches. [Allali, Mane; Amzazi, Saaïd]

Combination of Doxorubicin and Berberine Generated Synergistic Anticancer Effect on Breast Cancer Cells Through Down-regulation of Nanog and miRNA-21 Gene Expression
 MIDDLE EAST JOURNAL OF CANCER English
 Article Breast cancer; Nanog; miRNA-21; Doxorubicin; Berberine SIDE POPULATION; MIR-21; PROLIFERATION; SENSITIVITY; DIMINISHES; RESISTANCE; CISPLATIN; APOPTOSIS Background: Our purpose was to investigate the effect of berberine (BER) and doxorubicin (DOX) on the expression of stem cell markers Nanog and microRNA-21 in MCF-7 cells. Methods: The study was an in vitro study employing the human breast cancer cell line MCF-7 that was divided into four groups: Group MCF-7 cell line maintained in drug-free environment as untreated control, Group II: MCF-7 cell line treated with different concentrations of DOX, Group III: MCF-7 cell line treated with various concentrations of BER. Group IV: MCF-7 cell line treated with different concentrations of combined DOX and BER. MTT assay determined the metabolic activity and viability of MCF-7 cells for all groups. We further extracted total RNA from MCF-7 cells, and RT-PCR assayed the expression of Nanog and miRNA-21. Results: The results revealed that DOX and/or BER decreased the percentage of viable MCF-7 monolayer and mammospheres breast cancer cells in a concentration-dependent manner. Moreover, the combination of DOX and BER generated synergistic anticancer effect on MCF-7 monolayer cells and mammospheres. In addition, DOX alone, BER alone, and their combination significantly reduced Nanog and miRNA-21 gene expression in MCF-7 mammospheres compared with untreated mammospheres. Conclusions: BER may affect the viability of breast cancer cells through downregulation of Nanog and miRNA-21 gene expression, ultimately enhancing the sensitivity of breast cancer cell line to DOX. BER may be an effective chemotherapeutic agent against breast cancer where the combination of DOX and BER generates synergistic anticancer effects. Hamdey Rashed The Prognostic Significance of ALDH-1
and SOX9 Expression in Early Breast Cancer MIDDLE EAST JOURNAL
OF CANCER English Article

Egypt; Early breast cancer; Neoplastic stem cells;
Aldehyde dehydrogenase 1; SOX9; Prognosis ALDEHYDE
DEHYDROGENASE 1; POOR-PROGNOSIS; MARKER; PROLIFERATION; PREDICTOR;
CARCINOMA; ESTROGEN; CELLS Background: Aldehyde dehydrogenase 1
(ALDH1) is an enzyme accountable for the detoxification of
aldehydes. Sex-determining region Y-box 9 (SOX-9) plays a role in
many biological and pathological processes. In this study, we
aimed to evaluate the prognostic significance of ALDH1 and SOX9
expression in early breast cancer. Method: The expression of ALDH1
and SOX-9 was evaluated through immuno-histochemistry derived from
50 eligible patients with early breast cancer included in the
current prospective cohort study. Results: Positive expression of
ALDH1 and SOX-9 were detected in 29 (58%) and 34 (68%) patients,
respectively. The positive expressions of both markers were
statistically significant associated with increasing the stage,
lymph nodes metastasis, high Ki67 labeling index, and molecular
subtypes ($P < 0.001$), along with with the biological markers;
estrogen receptors, progesterone receptors, and human epidermal
growth factor receptor 2 over-expressions, and large tumor size (P
= 0.039, $P = 0.022$, $P = 0.024$ and $P = 0.003$ for ALDH1 expression
and $P = 0.012$, $P = 0.007$, $P = 0.004$, and $P = 0.002$ for SOX-9
expression, respectively). There is a significant positive
association between the expression of ALDH1 and SOX-9, r
(correlation coefficient) = +0.806 ($P < 0.001$). Local recurrence
was associated with the positive expression of ALDH1 only ($P =$
0.045) and the disease progression was statistically significant
and associated with the positive expression of both ALDH1 and SOX-
9 ($P = 0.038$, $P = 0.023$, respectively). There was significant
association of positive expression of SOX-9 with reduced 3-y
disease-free survival ($P = 0.039$). Conclusion: Positive expression
of ALDH-1 and SOX9 were associated with aggressive
histopathological features and poor outcome in early breast cancer
and can be considered potential prognostic markers in this group
of patients. [Abdelaziz, Lobna A.] Zagazig Univ, Fac Med, Dept

Androgen Receptor Expression in Triple-negative Breast Cancer and its Relation with Epidermal Growth Factor Receptor, CD 105, and Clinicopathological Parameters MIDDLE EAST JOURNAL OF CANCER English Article

Breast cancer; Androgen receptors; Immunohistochemistry BASAL-LIKE; MONOCLONAL-ANTIBODY; MOLECULAR CHARACTERIZATION; MICROVESSEL DENSITY; PHASE-II; EGFR; CARCINOMAS; MARKERS; FEATURES; TUMORS Background: Triple-negative breast cancers (TNBC) are the tumors lacking expression of estrogen receptors, progesterone receptors, and human epidermal growth factor 2. The highest level of androgen receptors (AR) expression belongs to the Luminal androgen receptor subtype. AR is expressed in 70 to 90% of primary breast cancers. The biological role of AR in breast cancer continues to emerge. The overexpression of epidermal growth factor receptor (EGFR) has been previously studied in TNBC, where it was found to be associated with poor prognosis. In the evaluation of neovascularization, CD105 (endoglin) was found to be superior to CD34 and CD31 owing to its greater affinity for endothelial cells in tumor-related angiogenic tissue. We conducted the present work to assess the expression profile of androgen receptor in TNBC cases and its correlation with other clinicopathological parameters, EGFR and CD 105, in order to evaluate its clinical significance. Method: This retrospective study included 50 histologically confirmed breast cancer patients who were proven to be triple-negative based on immunohistochemical study. Formalin-fixed tissue blocks with tumor were chosen for immunohistochemical staining for AR, EGFR, CD105, and Ki 67. Results: Positive AR expression was associated with older age, postmenopausal status, negative nodes, and grade II tumors. AR was inversely correlated with EGFR, while there was no correlation between AR and both Endoglin and Ki 67. Conclusion: AR-positive TNBC may be a subtype of breast cancer with unique characteristics that could make it ideal for antiandrogen endocrine therapy. EGFR and Endoglin's distinct expression indicated that they might be unique biomarkers for targeted therapy and prognosis. [El Badawy, Nehal Ahmed; Fadali, Geylan Abd

Analysis of Colorectal Cancer and Polyps for the Presence of Herpes Simplex Virus and Epstein - Barr virus DNA Sequences by Polymerase Chain Reaction MIDDLE EAST JOURNAL OF CANCER English Article

Colorectal cancer; Polyp; Herpes simplex virus; Epstein-Barr virus; Polymerase chain reaction

CYTOMEGALOVIRUS; ADENOCARCINOMA; CARCINOMA Background: Colorectal cancer is one of the most common malignancies worldwide with more than one million new cases diagnosed each year. The aim of this study is to investigate the prevalence of herpes simplex virus and Epstein-Barr virus in patients with colorectal carcinomas and polyps in comparison with healthy subjects by using the polymerase chain reaction technique. Methods: In this analytical case-control study, we selected 15 patients with colorectal cancer, 20 patients with colorectal polyps and 35 patients without malignancy as controls. Biopsy specimens were frozen under sterile conditions at -20 degrees C. After DNA extraction, analysis of polymerase chain reaction to detect herpes simplex virus and Epstein-Barr virus DNA in tissue samples was performed. Statistical analysis was performed with the chi 2 test. Results: We observed herpes simplex DNA in 33.3% of tumor samples (5 of 15) and 20% from the non-malignant control group (7 of 35). There was no herpes simplex DNA in the polyp tissues (0 of 20). Epstein-Barr DNA was found in 60% of tumor samples (9 of 15), 35% of polyp samples (7 of 20), and 40% of the non-malignant control group (14 of 35). Statistical analysis showed no significant association between the prevalence of herpes simplex and Epstein-Barr viruses and the incidence of colorectal cancer and polyps compared with the control group. Conclusion: The results demonstrate a lack of direct molecular evidence to support an association between herpes simplex and Epstein-Barr viruses with human colorectal malignancies. These results do not exclude a possible oncogenic role of these viruses to infect different colon cells.

J Arizpe, A; Navarro, S; Ochoa-Dominguez, CY; Rodriguez, C; Kim, SE; Farias, AJ Arizpe, Angel; Navarro, Stephanie; Ochoa-Dominguez, Carol Y.; Rodriguez, Claudia; Kim, Sue E.; Farias, Albert J. Nativity differences in socioeconomic barriers and healthcare delays among cancer survivors in the All of Us cohort CANCER CAUSES & CONTROL English Article SES

barriers; Healthcare delays; Nativity; All of Us; Cancer survivors; Health literacy LIFE-STYLE FACTORS; PHYSICAL-ACTIVITY; MEDITERRANEAN DIET; STAGE-III; QUESTIONNAIRE; VALIDITY; RISK; ASSOCIATION; RECURRENCE; PREVENTION PurposeWe aimed to assess whether nativity differences in socioeconomic (SES) barriers and health literacy were associated with healthcare delays among US cancer survivors.Methods"All of Us" survey data were analyzed among adult participants ever diagnosed with cancer. A binary measure of healthcare delay (1+ delays versus no delays) was created. Health literacy was assessed using the Brief Health Literacy Screen. A composite measure of SES barriers (education, employment, housing, income, and insurance statuses) was created as 0, 1, 2, or 3+. Multivariable logistic regression model tested the associations of (1) SES barriers and health literacy with healthcare delays, and (2) whether nativity modified this relationship.ResultsMedian participant age was 64 years (n = 10,020), with 8% foreign-born and 18% ethnic minorities. Compared to survivors with no SES barriers, those with 3+ had higher likelihood of experiencing healthcare delays (OR 2.18, 95% CI 1.84, 2.58). For every additional barrier, the odds of healthcare delays were greater among foreign-born (1.72, 1.43, 2.08) than US-born (1.27, 1.21, 1.34). For every 1-unit increase in health literacy among US-born, the odds of healthcare delay decreased by 9% (0.91, 0.89, 0.94).ConclusionWe found that SES barriers to healthcare delays have a greater impact among foreign-born than US-born cancer survivors. Higher health literacy may mitigate healthcare delays among US cancer survivors. Healthcare providers, systems and policymakers should assess and address social determinants of health and promote health literacy as a way to minimize healthcare delays among both foreign- and US-born cancer survivors. Cell Death and Tumor Metastases: A Potential Dual Response During
Colorectal Cancer Development MIDDLE EAST JOURNAL OF CANCER
English Article
Colorectal cancer; Hsa-miR-21; Dual response EXPRESSION;
RISK Background: Colorectal cancer (CRC), caused by abnormal
cells growing in the colon or rectum, has a high mortality rate
worldwide. On the other hand, microRNAs are small non-coding RNAs
that contain approximately 22 nucleotides in length. They are
upregulated in a wide range of human cancers such as CRC. MiRNA-21
post-transcriptionally regulates the expression of many tumor
suppressor genes such as P53 gene. This indicates that miRNA-21
interacts like oncogenes and is required for CRC development.
Method: The current original study was conducted in the National
Liver Institute, Menofya University, Egypt. We collected a total
of 40 blood samples from CRC patients 40 samples from healthy
individuals who served as controls. Quantitative real-time PCR
detected the levels of miRNA-21 and the fold changes of
phosphates-tensin homology (PTEN) gene expression, as a tumor
suppressor gene, in blood samples. Results: The expression levels
of miR-21 were upregulated in all obtained samples from patients
with CRC in association with aging, gender, and tumor-node-
metastasis staging. Furthermore, patients with poor and well-

differentiated CRC revealed reduced levels of PTEN gene expression. We observed a putative binding site of miR-21 in PTEN gene sequences. This indicates the direct cleavage between miR-21 and PTEN coding sequence. Prediction analysis for other potential targets identified several malignancy factors and tumor suppressor genes with putative seeding regions for miR-21 such as STAT3, transforming growth factor-beta, tumor necrosis factor-alpha (TNF-alpha), and programmed cell death CD4. Conclusion: The current data exhibited the potential dual role of hsa-miR-21 in regulating cancer progression and showed that hsa-miR-21 is an efficacious biomarker for CRC development and an attractive candidate for CRC treatment during early transformation. specific micronutrient intake in colorectal cancer patients with
 tumors presenting Ki-ras mutation ANTICANCER RESEARCH

English Article

colorectal cancer risk; Ki-ras; diet; vitamin A; thiamine;
 vitamin D; iron COLON-CANCER; PROGNOSTIC VALUE; GENE-MUTATIONS;
 DEPENDENT RISK; SEQUENCE; PROTOONCOGENE; EPIDEMIOLOGY; RETINOIDS;
 CARCINOMA; ADENOMAS Background: The diversity of the
 Mediterranean diet and the heterogeneity of acquired genetic
 alterations in colorectal cancer (CRC) led us to examine the
 possible association between dietary factors and mutations, such
 as Ki-ras mutations, in genes implicated in the pathogenesis of
 these neoplasms. Patients and Methods: The study was based on 246
 cases and 296 controls. For the molecular study only 117 patients
 with Ki-ras tumor expression were included. Dietary patterns were
 assessed using a semi-quantitative food frequency questionnaire.
 Results: Patients with Ki-ras mutations in codon 12 (K12) consumed

significantly less vitamin A ($p = 0.02$), B1 ($p = 0.01$), D ($p = 0.02$) and iron ($p = 0.03$) than controls, whereas patients without these mutations had similar intakes of these nutrients to controls. The consumption of fiber, folate, vitamin E and potassium was lower in the two subgroups of patients (K12-positive or -negative) than in controls. Mutation in codon 13 was not associated with any nutrient deficit. Conclusion: These results support previous findings that certain micronutrients protect against colorectal neoplasia and emphasize the importance of considering the different molecular forms of CRC as etiologically distinct diseases.

Quality Indices and Postmenopausal Breast Cancer Survival

NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL English Article

FOOD-FREQUENCY QUESTIONNAIRE; CORONARY-HEART-DISEASE; NATIONAL DEATH INDEX; LIFE-STYLE; MEDITERRANEAN DIET; PROSPECTIVE COHORT; WEIGHT-GAIN; WOMEN; DIAGNOSIS; MORTALITY Research on diet in breast cancer survival has been focused on single nutrients or foods, particularly dietary fat, fruits, vegetables, fiber, and alcohol. We hypothesized that diet quality indices decrease the risk of total and non-breast-cancer-related deaths in women diagnosed with breast cancer. We evaluated 4 dietary quality scores: Alternate Healthy Eating Index (AHEI), Diet Quality Index Revised (DQIR), Recommended Food Score (RFS), and the alternate Mediterranean Diet Score (aMED), among 2,729 women from the Nurses' Health Study with invasive Stage 1-3 breast cancer diagnosed between 1978 and 1998 with follow-up through 2004. In

multivariate adjusted analyses, no association was found between diet quality indices and either total or non-breast-cancer-related deaths. However, a higher aMED score was associated with a lower risk of non-breast-cancer death in women with low physical activity; the RR comparing the highest to lowest tertile was 0.39 (95% CI, 0.20-0.75, P trend = 0.0004). Our results suggest that a higher-quality diet after breast cancer diagnosis does not considerably change the risk of death from breast cancer. However, healthy dietary choices may be important because women are at risk of death from non-breast-cancer-related causes affected by diet.

Endoplasmic Reticulum Stress-Induced Apoptotic
Effects of Novel 1-Pyrroline (3,4-Dihydro-2H-pyrrole) Derivatives
on Breast Cancer Cells CHEMISTRY & BIODIVERSITY
English Article 1-
pyrroline; apoptosis; ER stress; breast cancer

Heterocyclic compounds have emerged as promising and appealing scaffolds for developing effective antitumor agents. Here, the effects of synthesized 24 different 1-pyrroline derivatives (PDs) containing substituted aryl sulfide moiety were investigated on human breast cancer cell lines. The viability of cells was assessed via MTT assay. Reactive oxygen species (ROS) generation was analyzed via fluorescent dye CM-H2DCFDA. Apoptotic cells were determined via flow cytometry. Endoplasmic reticulum (ER) stress-associated protein levels were analyzed via western blot analysis. Four of the PDs (PD-12, -14, -16 and -17) had great cytotoxic selectivity against breast cancer cells. Apoptotic cell death was induced by PDs via the generation of ROS. PDs significantly increased the GRP78, p-PEAK, p-eIF2 alpha, and CHOP

protein levels indicating ER stress in breast cancer cells. These results imply that newly synthesized PDs may be potential anticancer agents as they selectively inhibit breast cancer cells.

Correlation between KRAS and NRAS mutational status and clinicopathological features in 414 cases of metastatic colorectal cancer in Morocco: the largest North African case series BMC GASTROENTEROLOGY English Article

KRAS; NRAS; Colorectal neoplasms; Metastases;
North Africa K-RAS; EGYPTIAN PATIENTS; BRAF MUTATIONS; COLON-
CANCER; ASSOCIATION; GENE; P53 BackgroundAdvances in molecular biology have improved understanding of the molecular features of carcinogenesis and progression of colorectal cancer. It is clear that the efficacy of anti-EGFR depends upon the RAS mutational status, since any mutation in RAS is associated with resistance to anti-EGFR therapy. The aim of this study is to report the largest North African description of KRAS and NRAS status in metastatic colorectal cancer and to describe the association of these mutations with clinicopathological characteristics.MethodsThis is a prospective study of all consecutive unselected metastatic colorectal cancer samples, collected from the Laboratory of Pathology at the National Institute of Oncology of Rabat, Morocco, from January 1st 2020 to December 31st 2021. The molecular analysis was performed on the Idylla (TM) platform (fully automated real-time polymerase chain reaction-based assay) for KRAS and NRAS mutations in exons 2, 3 and 4. These mutations were correlated to gender, primary tumor site, histological type and degree of differentiation of tumor using adequate statistical

methods. Results Four hundred fourteen colorectal tumors were screened for KRAS and NRAS mutations. These mutations occurred in 51.7% of tumors for KRAS (mainly in exon 12) and in 3% of tumors for NRAS. There was a significant correlation between NRAS mutation and age of colorectal patients in this study. The low rate of invalid RAS tests (1.7% for KRAS and 3.1% for NRAS) was certainly obtained due to the strict respect of pre-analytical factors such as cold ischemia time and formalin fixation. Conclusion We report the largest North African analysis of NRAS and KRAS status in colorectal metastatic patients. This study showed the ability in low middle income countries to perform a high rate of valid tests and the unusual trend towards older patients for NRAS mutations.  Scorzonera; seeds; polyphenols; LC-PDA-MS; GC-MS; breast cancer; biological activity PHENOLIC-COMPOUNDS; ESTROGEN-RECEPTOR; MEDICINAL-PLANTS; APOPTOSIS; ACID; (-)-SYRINGARESINOL; SESQUITERPENOID; INTERLEUKIN-10; CONSTITUENTS; METABOLITES Scorzonera hispanica is an herbaceous perennial cultivated in Central and Southern Europe. This study aimed to qualitatively and quantitatively evaluate the composition of oil, extracts, and fractions (SH1-SH12) obtained from S. hispanica seeds. Furthermore, an evaluation of biological activities in breast cancer cell lines was also performed. GC-MS analysis revealed that the primary components of the seed oil (SH12) were fatty acids and beta-sitosterol. In the evaluation of extracts

(SH1-SH3, SH8-SH10) and fractions (SH4-SH7, SH11) composition, the presence of apigenin, derivatives of p-coumaric and caffeic acids, was reported. In the biological assays, methanolic extract (SH1), diethyl ether (SH4), and chloroform (SH11) fractions exhibited cytotoxicity toward cells. The highest activity was observed for fatty acids- and 3,4-dimethoxycinnamate-rich SH11 (IC50: 399.18 μ g/mL for MCF-7, 781.26 μ g/mL for MDA-MB-231). SH11 was also observed to induce apoptosis in MCF-7 cells (52.4%). SH1, SH4, and SH11 attenuate signaling pathways and affect the expression of apoptosis-, autophagy-, and inflammation-related proteins. SH12 was non-toxic toward either cancer or normal cell lines in concentrations up to 1 mg/mL. The results suggest that S.

hispanica seeds exhibit a wide range of potential uses as a source of oil and bioactive compounds for complementary therapy of breast cancer. apoptosis; breast cancer; G0; G1 arrest; N-propargylic beta-enaminone; ROS level BIOLOGICAL-ACTIVITY; TRABECTEDIN

Breast cancer is one of the most common cancers worldwide and the discovery of new cytotoxic agents is needed. Enaminones are regarded to be a significant structural motif that is found in a variety of pharmacologically active compounds however the number of studies investigating the anticancer activities of N-propargylic beta-enaminones (NPEs) is limited. Herein we investigated the potential cytotoxic and apoptotic effects of 23 different NPEs (1-23) on human breast cancer cells. Cytotoxicity was evaluated via MTT assay. Apoptotic cell death and cell cycle distributions were investigated by flow cytometry. CM-H2DCFDA dye was used to evaluate cellular ROS levels. Expression levels of Bcl-2, Bax, p21, and Cyclin D1 were measured by quantitative real-time PCR. ADME properties were calculated using the ADMET 2.0 tool. NPEs 4, 9, 16, and 21 showed selective cytotoxic activity against breast cancer cells with SI values > 2. NPEs induced apoptosis and caused significant changes in Bcl-2 and Bax mRNA levels. The cell cycle was arrested at the G0/G1 phase and levels of p21 and Cyclin D1 were upregulated in both breast cancer cells. ROS levels were significantly increased by NPEs, suggesting that the cytotoxic and apoptotic effects of NPEs were mediated by ROS. ADME analysis revealed that NPEs showed favorable distributions in both breast cancer cell lines, meaning good lipophilicity values, low unfractionated values, and high bioavailability. Therefore, these potential anticancer compounds should be further validated by in vivo studies for their appropriate function in human health with a safety profile, and a comprehensive drug interaction study should be performed. Trends and Symptoms Among Increasing Proportion of African Americans with Early-Onset Colorectal Cancer over a 60-Year Period
DIGESTIVE DISEASES AND SCIENCES
English Article

Early-onset; Late-onset; African Americans; Colorectal cancer
AGE; DISPARITIES; STATISTICS; GUIDELINES; FEATURES; BIOLOGY; TIME
Background The proportion of early onset colorectal cancer (EOCRC) is alarming in adults, including in African Americans (AA). Aim To investigate differences between EOCRC compared to late-onset colorectal cancer (LOCRC) among AA patients. Methods This retrospective study reviewed demographic, clinical presentations, colonoscopy, and pathology reports of patients at Howard University Hospital from 1959 to 2023. The study included 176 EOCRC cases (< 45 years) and 2034 LOCRC cases (> 45 years). Results Both EOCRC and LOCRC groups were predominantly AA (> 80%) with slightly more females (53%) than males. The mean age was 38 years for EOCRC and 66 years for LOCRC cases. EOCRC cases increased as a proportion of total detected CRC cases since 2010 (over 13%) after several decades of just above 6%. Family history of CRC in first degree relatives was higher among EOCRC (15.5% vs. 3.4% in LOCRC patients, $p < 0.01$). Symptoms at presentation were prevalent in both EOCRC (93.8%) and LOCRC (92.6%). EOCRC patients exhibited higher incidence of abdominal pain (23.3% vs. 17.2%, $p = 0.05$) and changes in bowel habits (24.4% vs. 14%, $p < 0.01$) compared to LOCRC patients. Other symptoms such as melena, hematochezia, and weight loss were less prevalent in EOCRC patients. Comorbidities like hypertension (HTN), diabetes mellitus (DM), and inflammatory bowel disease (IBD) were less frequent among EOCRC patients. EOCRC was primarily observed in the sigmoid and rectosigmoid regions ($p = 0.02$). Metastasis at index colonoscopy was more prevalent with EOCRC compared to LOCRC ($p = 0.04$), with a higher proportion of patients at stage 3 cancer ($p < 0.05$). Significant differences were noted in the timeline for undergoing surgery after the diagnosis of colorectal cancer, with EOCRC patients taking longer than LOCRC patients ($p = 0.03$). Conclusion Presentation of EOCRC over LOCRC increased proportionally in our cohort since 2010 and is associated with family history, and symptoms such as abdominal pain and change in bowel habits. Likely because of age at presentation, there are less comorbidities among EOCRC patients who predominantly present in the outpatient setting, and more likely diagnosed with advanced stage lesions that are predominantly sigmoid or rectosigmoid. These findings are similar to observations seen in the general population with EOCRC, albeit African American patients have commonly had earlier age

presentation of CRC than White American patients. Screening programs for colorectal cancer in Greece: Results of two pilot studies conducted in March 2008 and 2009 ANNALS OF GASTROENTEROLOGY English Article

Colorectal cancer; screening; surveillance; fecal occult blood test; prevention

Background: Detection of occult blood in stools is an established method for the early detection of colorectal cancer in asymptomatic individuals of average risk. The aim of this study was to present the results derived from the application of the test in a cohort of Greek population of average risk. Subjects and Methods: We conducted two pilot studies in March 2008 and 2009 respectively. The first was conducted only in the greater area of Athens while the second one included two more major cities in the North and South part of the country (Salonika and Iraklion, Crete). In both campaigns all residents, aged between 55 and 72 years were asked through relevant television spots, articles in

newspapers, radio spots and press conferences to participate in both studies (March 2008 and March 2009), by submitting a stool sample in the nearest "Biomedicine" Laboratory. For the detection of haemoglobin in stools LINEAR immunochemical FOBT was applied. This test is a qualitative, lateral flow immunoassay for the detection of human hemoglobin in stools. In order to include in the statistical analysis more than 90% of all examined individuals, we divided the number of subjects participating in the 2009 trial into three groups aged 55-60, 61-66, and 67-72 years. Moreover, in order to be able to calculate the odds ratios, these groups were transformed from numerical to nominal ones. Statistical analysis was performed using Pearson chi square test. Results: 1st trial, March 2008: The total number of individuals examined was 4,010. The rate of positivity was 9.83% (394 out of 4,010 individuals examined). Among the positive samples 30.2% corresponded to subjects aged 55-60 years, 35.3% to subjects aged 61-65 years and 34.5% to subjects aged 65-70 years. 2nd trial, March 2009: The total number of individuals tested was 7,079 with 3,131 (44.2%) being men and 3,948 (55.8%) being women. The participation rate was: Athens 5,037 (71.1%), Salonika 1,407 (19.9%) and Iraklion 635 subjects (9.0%). The positivity rate was 11.1% (786 out of 7,079 subjects). The positivity rate among men (11.9%) (373/3,131) was higher compared to women (10.5%) (413/3,948) although this difference did not reach statistical significance ($P=0.057$). Mean age of the positive subjects was statistically significantly higher compared to negative ones (62.4 vs 61.9yrs, $P=0.01$). Significant differences existed between group 1 (55-60 years) vs group 3 (67-72 years). So, the probability of a positive test in the age of 67-72 was 1.36 times higher than at the age of 55-60 and the probability of a positive test in the age of 67-72 was 1.26 times higher than at the age of 61-66. Statistically significant difference in the positivity rate of the test between the three areas was noticed. So, residence was responsible for the variation in positive rate of FOBT by 6.9% (Eta statistics). Conclusion: The rate of positivity of iFOBT in Greece is in accordance with that reported in the relevant international literature and remains steady, at least during the years 2008 and 2009. However, it seems to be lower in areas adopting the so called Mediterranean diet (Iraklion, Crete). Taking into account the number of inhabitants of the country over the age of 55, we can assume that the compliance of the Greek population in colorectal cancer screening programs is relatively low. In the forthcoming years, screening programs in Greece must be adopted by the health authorities of the country in order to cover a larger part of the population. The experience derived from our studies could result in more successive and productive future programs. [Triantafyllidis, J.  Diet Quality and All-Cause Mortality in Women
 with Breast Cancer from the Breast Cancer Family Registry
 CANCER EPIDEMIOLOGY BIOMARKERS & PREVENTION
 English Article
 POSTMENOPAUSAL WOMEN; MULTIETHNIC COHORT; DISEASE MORTALITY;
 INDEXES; RISK; HYPERTENSION; ADHERENCE; SURVIVORS; PATTERNS;
 ASSOCIATION
 Background: The impact of diet on breast cancer
 survival remains inconclusive. We assessed associations of all-
 cause mor-tality with adherence to the four diet quality indices:
 Healthy Eating Index-2015 (HEI-2015), Alternative Healthy Eating
 Index (AHEI), Alternative Mediterranean Diet (aMED), and Dietary
 Approaches to Stop Hypertension (DASH). Methods: Dietary intake
 data were evaluated for 6,157 North American women enrolled in the
 Breast Cancer Family Registry who had been diagnosed with invasive
 breast cancer from 1993 to 2011 and were followed through 2018.
 Pre-diagnosis (n = 4,557) or post-diagnosis (n = 1,600) dietary
 intake was estimated through a food frequency questionnaire.
 During a median follow-up time of 11.3 years, 1,265 deaths
 occurred. Cox proportional hazards models were used to estimate
 multivariable-adjusted HR and 95% confi- dence intervals
 (CI). Results: Women in the highest versus lowest quartile of
 adher-ence to the HEI-2015, AHEI, aMED, and DASH indices had a
 lower risk of all-cause mortality. HR (95% CI) were 0.88 (0.74-
 1.04; Ptrend = 0.12) for HEI-2015; 0.82 (0.69-0.97; Ptrend = 0.02)
 for AHEI; 0.73 (0.59-0.92; Ptrend = 0.02) for aMED; and 0.78
 (0.65-0.94; Ptrend = 0.006) for DASH. In subgroup analyses, the
 associations with higher adherence to the four indices were
 similar for pre-or post-diagnosis dietary intake and were confined
 to women with a body mass index <25 kg/m2 and women with hormone
 receptor positive tumors. Conclusions: Higher adherence to the
 HEI-2015, AHEI, aMED, and DASH indices was associated with lower
 mortality among women with breast cancer. Impact: Adherence to a
 healthy diet may improve survival of women with breast cancer.

COLORECTAL CANCER AND INFLAMMATORY BOWEL DISEASES: EFFECTS
 OF DIET AND ANTIOXIDANTS JOURNAL OF BIOLOGICAL REGULATORS AND
 HOMEOSTATIC AGENTS English Article

inflammatory bowel diseases; IBD;
 colorectal cancer; antioxidant; anti-inflammatory activity of tea
 COLON-CANCER; GREEN TEA; CELLS; POLYPHENOLS; INHIBITION;
 INDUCTION; GROWTH It is well established that oxidative
 stress is common in inflammatory bowel diseases (IBDs).
 Accordingly, antioxidants are recommended for treatment. The aim

of this study is to compare the effects of antioxidants contained in the various types of tea on symptoms and evolution of IBD and colorectal cancer (CRC). Analysis of the literature revealed that the theaflavin-3, 30-digallate (TFDG) contained in black tea, and epigallocatechin-3-O-gallate (EGCG) contained in green tea have protective effects against oxidative stress. Moreover, these substances are involved in many biochemical processes responsible for inflammation and proliferation of cancer cells. It is documented that both TFDG and EGCG are able to reduce inflammatory phenomena and symptoms associated with IBD, as well as to reduce the proliferation of CRC cells. Most studies are performed in vitro or in experimental animal models. It is, therefore, advisable to formulate studies that could be carried out on humans or human samples, in order to develop the appropriate therapeutic strategies. Murtaugh, Maureen A.; Sweeney, Carol; Giuliano, Anna R.; Herrick, Jennifer S.; Hines, Lisa; Byers, Tim; Baumgartner, Kathy B.; Slattery, Martha L. Diet patterns and breast cancer risk in Hispanic and non-Hispanic white women: the Four-Corners Breast Cancer Study AMERICAN JOURNAL OF CLINICAL NUTRITION English Article

PROSPECTIVE COHORT; OBESITY; OVERWEIGHT; HISTORY; WEIGHT; FATBackground: There is a lower incidence of breast cancer among Hispanic women than among non-Hispanic white women. Little is known about the role of diet in this difference. Objective: We examined the associations of dietary patterns (Western, Prudent, Native Mexican, Mediterranean, and Dieter) with risk for breast cancer in Hispanic women (757 cases, 867 controls) and non-Hispanic white women (1524 cases, 1598 controls) from the Four-Corners Breast Cancer Study. Design: Dietary intake, physical

activity, and other exposures were assessed by using interviews. Dietary patterns were defined via factor analysis. Risk was assessed by using logistic regression with adjustment for age, center, education, smoking, total activity, calories, dietary fiber, dietary calcium, height, parity, recent hormone exposure, family history of breast cancer, menopausal status, and body mass index X recent hormone exposure. Results: The Western (odds ratio for highest versus lowest quartile: 1.32; 95% CI: 1.04,168; P for trend < 0.01) and Prudent (1.42; 1. 1.4, 1.77; P for trend < 0.01) dietary patterns were associated with greater risk, and the Native Mexican (0.68; 0.55, 0.85; P for trend < 0.01) and Mediterranean (0.76; 0.63, 0.92; P for trend < 0.01) dietary patterns were associated with lower risk of breast cancer. Body mass index modified the associations of the Western diet and breast cancer among postmenopausal women and those of the Native Mexican diet among premenopausal women. Conclusions: Associations of dietary patterns with breast cancer risk varied by menopausal and body mass index status, but there was little difference in associations between non-Hispanic white and Hispanic women. J Shirkhani, M; Heydarheydari, S; Farshchian, N; Eivazi, MT; Haghparsat, A Shirkhani, Mostafa; Heydarheydari, Sahel; Farshchian, Negin; Eivazi, Mohammad Taghi; Haghparsat, Abbas Fetal Dose Estimation for Pregnant Breast Cancer Patients during Radiotherapy Using an In-house Phantom MIDDLE EAST JOURNAL OF CANCER

English Article Breast cancer; Radiation therapy; Fetal dose Background: Up to 3% of breast cancers may be diagnosed in pregnancy, during which period radiation therapy is not preferred, yet sometimes

inevitable. Due to fetal radiation sensitivity, the fetal radiation safety is of particular concern. The present study was performed to estimate fetal dose for pregnant breast cancer patients during radiotherapy using an in-house phantom. Method: The fetal dose was estimated through phantom measurement using an ion chamber dosimeter. The phantom measurement was performed by simulating treatment planning on an in-house anthropomorphic phantom which consisted of natural human bone, cork, and paraffin. The right breast and the right supraclavicular area of the phantom were irradiated under the four-field technique with 6 and 10 MV photon beams for un-wedged and wedged fields. Results: During the first trimester of pregnancy, the radiation dose delivered to the fetus was in the range of 0.11-0.14 Gy for a 50 Gy total tumor dose in 25 fractions. The fetal dose in the second and third trimester of pregnancy ranged from 0.14-0.19 Gy to 0.22-0.32 Gy, respectively. Conclusion: According to the results, the fetal dose is strongly dependent upon the energy beam, treatment procedure, and gestational stage. Expression Pattern of AIFM3, VGLL4, and WNT4 in Patients with Different Stages of Colorectal Cancer CANCERS

English Article

colorectal cancer; AIFM3; VGLL4; WNT4 MICROSATELLITE
INSTABILITY Background/Objectives: Colorectal cancer (CRC) remains a significant health burden, and its delayed diagnosis at advanced stages leads to poor survival outcome. Detection of known and novel prognostic markers is essential. In this study, the status

of likely prognostic markers-the apoptotic inducing factor (AIFM3), vestigial-like family member 4 (VGLL4), and WNT4-was evaluated. Methods: AIFM3, VGLL4, and WNT4 expression in CRC tissues across different stages (Dukes A-D) were analyzed using histological immunofluorescence staining and RNA sequencing analyses. Results: In advanced CRC stages, progressive loss of normal crypt architecture, reduction of goblet cells, and necrotic debris were detected along with differential expression patterns of AIFM3, VGLL4, and WNT4. AIFM3 exhibited high reactivity in the lamina propria of healthy tissue and Dukes A, but this was diminished in advanced CRC stages. VGLL4 expression, initially confined to the lamina propria, increased significantly in the epithelium of Dukes B and C, with a cytoplasmic localization pattern. WNT4 expression was elevated in the CRC epithelium across all stages, contrasting with a significant reduction in lamina propria reactivity. RNA sequencing corroborated these findings, showing significant downregulation of AIFM3 and WNT4 and upregulation of VGLL4 in CRC tissues compared to controls. Expression of AIFM3 and WNT4 showed no correlation with survival outcome, while low VGLL4 expression was correlated with better survival outcome. Conclusions: The results suggest distinct roles for AIFM3, VGLL4, and WNT4 in CRC progression, highlighting only VGLL4 as a potential prognostic marker. Further evaluation of VGLL4 and its specific role in CRC progression remains to be elucidated. J Madani, SH; Payandeh, M; Sadeghi, M; Motamed, H; Sadeghi, E
Madani, Seyed-Hamid; Payandeh, Mehrdad;
Sadeghi, Masoud; Motamed, Hajar; Sadeghi, Edris The
correlation between Ki-67 with other prognostic factors in breast
cancer: A study in Iranian patients INDIAN JOURNAL OF MEDICAL
AND PAEDIATRIC ONCOLOGY English Article
Breast cancer; histological grade; Ki-
67; P53 PROLIFERATION MARKERS; KI67; P53; ASSOCIATION;
EXPRESSION; CARCINOMA; TUMOR; METAANALYSIS; FRACTION; INDEX

Context: Despite the fact that breast cancer (BC) is a major
health issue, very few studies describe its characteristics in the
Middle East. Aim: The aim of this study was to evaluate the use
and value of Ki-67 as a prognostic marker in BC and associations
between Ki-67, clinical, and histopathological parameters were
evaluated. Subjects and Methods: In a retrospective study, 260 BC
women and invasive ductal carcinoma were included to our study in
Kermanshah city, Iran. Age, tumor size, lymph node involvement,
histological grade, nuclear grade, and vascular invasion were
other factors that determined in a lot of patients. Results: The
mean age at diagnosis was 47.6 years (range, 24-84 years) with
100% female. Of 243 patients that tumor size was determined for
them, 207 patients (85.2%) had tumor size ≥ 2 cm, and 36 patients
(14.8%) had size < 2 cm and also of 237 patients, 47 patients
(19.8%), 140 (59.1%), and 50 (21.1%) had histological grades I,
II, and III, respectively. There is significant correlation
between Ki-67 with nuclear grade, human epidermal growth factor
receptor 2 (HER2), and p53 ($P < 0.05$). Based on this result, more
patients with Ki-67 $\geq 20\%$ have higher nuclear grade, p53-
positive, and HER2-positive. There was correlation between Ki-67
with type of tumor ($P = 0.009$). Conclusions: The higher Ki-67 has
a direct significant correlation with higher nuclear grade, p53-
positive, and HER2-positive. Furthermore, triple negative patients
have higher Ki-67 compared to other subtypes. [Madani, Seyed-

Deciphering the Methylation Landscape in Breast Cancer:
Diagnostic and Prognostic Biosignatures through Automated Machine
Learning CANCERS English Article

breast cancer; methylation; machine
learning; signature; predictive model; bioinformatics; pathway;
transcription DNA METHYLATION; COMPREHENSIVE ANALYSIS; CELL-
PROLIFERATION; TISSUE INHIBITOR; GROWTH; EXPRESSION; PREDICTION;
SIGNATURE; GENE; AIM2 Simple Summary Breast cancer (BrCa) is
characterized by aberrant DNA methylation. We leveraged high-
throughput methylation data from BrCa and normal breast tissues
and identified 11,176 to 27,786 differentially methylated genes
(DMGs) against clinically relevant end-points. Innovative
automated machine learning was employed to construct three highly
performing signatures for (1) the discrimination of BrCa patients
from healthy individuals, (2) the identification of BrCa
metastatic disease and (3) the early diagnosis of BrCa.
Furthermore, functional analysis revealed that most genes selected
in the signatures showed associations to BrCa, with regulation of
transcription being the main biological process, the nucleus being
the main cellular component and transcription factor activity and
sequence-specific DNA binding being the main molecular functions.
Overall, revisiting methylome datasets led to three high-
performance signatures that are readily available for improving
BrCa precision management and significant knowledge mining related
to disease pathophysiology. DNA methylation plays an important
role in breast cancer (BrCa) pathogenesis and could contribute to
driving its personalized management. We performed a complete
bioinformatic analysis in BrCa whole methylome datasets, analyzed
using the Illumina methylation 450 bead-chip array. Differential
methylation analysis vs. clinical end-points resulted in 11,176 to
27,786 differentially methylated genes (DMGs). Innovative
automated machine learning (AutoML) was employed to construct
signatures with translational value. Three highly performing and
low-feature-number signatures were built: (1) A 5-gene signature
discriminating BrCa patients from healthy individuals (area under
the curve (AUC): 0.994 (0.982-1.000)). (2) A 3-gene signature
identifying BrCa metastatic disease (AUC: 0.986 (0.921-1.000)).
(3) Six equivalent 5-gene signatures diagnosing early disease
(AUC: 0.973 (0.920-1.000)). Validation in independent patient
groups verified performance. Bioinformatic tools for functional
analysis and protein interaction prediction were also employed.
All protein encoding features included in the signatures were
associated with BrCa-related pathways. Functional analysis of DMGs
highlighted the regulation of transcription as the main biological
process, the nucleus as the main cellular component and
transcription factor activity and sequence-specific DNA binding as

the main molecular functions. Overall, three high-performance diagnostic/prognostic signatures were built and are readily available for improving BrCa precision management upon prospective clinical validation. Revisiting archived methylomes through novel bioinformatic approaches revealed significant clarifying knowledge for the contribution of gene methylation events in breast carcinogenesis. Disparities in Awareness of Myocardial Infarction and Stroke Symptoms and Response Among United States- and Foreign-Born Adults in the National Health Interview Survey JOURNAL OF THE AMERICAN HEART ASSOCIATION English Article

cardiovascular disease; disparities; health education; heart attack; immigrants; stroke HEART-ATTACK

Background Atherosclerotic cardiovascular disease, defined as nonfatal myocardial infarction (MI), coronary heart disease death, or fatal or nonfatal stroke, is the leading cause of death in the United States. MI and stroke symptom awareness and response reduce delays in hospitalization and mortality. Methods and Results We analyzed cross-sectional data from the 2014 and 2017 National Health Interview Surveys on US- and foreign-born adults from 9 regions of birth (Europe, South America, Mexico/Central America/Caribbean, Russia, Africa, Middle East, Indian subcontinent, Asia, and Southeast Asia). The outcomes were recommended MI and stroke knowledge, defined as knowing all 5 symptoms of MI or stroke, respectively, and choosing "call 9-1-1" as the best response. We included 63 059 participants, with a mean age 49.4 years; 54.1% were women, and 38.5% had a high school education or less. Recommended MI and stroke knowledge were highest in US-born people. In both 2014 and 2017, MI knowledge was lowest in individuals born in Asia (23.9% $\pm$ 2.5% and 32.1% $\pm$ 3.3%, respectively), and stroke knowledge lowest for the Indian subcontinent (44.4% $\pm$ 2.4% and 46.0% $\pm$ 3.2%, respectively). Among foreign-born adults, people from Russia and Europe had the highest prevalence of recommended MI knowledge in 2014 (37.4% $\pm$ 5.4%) and 2017 (43.5% $\pm$ 2.5%), respectively, and recommended stroke knowledge was highest in people from Europe (61.0% $\pm$ 2.6% and 67.2% $\pm$ 2.5%). Improvement in knowledge was not significant in all groups between 2014 and 2017. Conclusions These findings suggest a disparity in MI and stroke symptom awareness and response among immigrants in the United States. Culturally tailored public health education and health literacy initiatives are needed to help reduce these disparities in awareness.

Extract Induces Apoptosis via P53 and Signal Transducer and
 Activator of Transcription 3 Signaling Pathways in Triple-Negative
 Breast Cancer Cells FRONTIERS IN NUTRITION English

Article

Elaeagnus

angustifolia; triple-negative breast cancer; apoptosis; stat3; p53

NATURAL-PRODUCTS; STAT3; RESISTANCE; DISCOVERY; PATTERNS;

TARGET; L. Elaeagnus angustifolia (EA) is used as an alternative
 medicine in the Middle East to manage numerous human diseases. We
 recently reported that EA flower extract inhibits cell
 proliferation and invasion of human oral and HER2-positive breast
 cancer cells. Nevertheless, the outcome of EA extract on triple-
 negative breast cancer (TNBC) cells has not been explored yet. We
 herein investigate the effect of the aqueous EA extract (100 and
 200 μ l/ml) on two TNBC cell lines (MDA-MB-231 and MDA-MB-436)
 for 48 h and explore its underlying molecular pathways. Our data
 revealed that EA extract suppresses cell proliferation by
 approximately 50% and alters cell-cycle progression of these two
 cancer cell lines. Additionally, EA extract induces cell apoptosis
 by 40-50%, accompanied by the upregulation of pro-apoptotic
 markers (Bax and cleaved caspase-8) and downregulation of the
 anti-apoptotic marker, Bcl-2. Moreover, EA extract inhibits colony
 formation compared to their matched control. More significantly,
 the molecular pathway analysis of EA-treated cells revealed that
 EA extract enhances p53 expression, while inhibiting the
 expression of total and phosphorylated Signal Transducer and
 Activator Of Transcription 3 (STAT3) in both cell lines,
 suggesting p53 and STAT3 are the main key players behind the
 biological events provoked by the extract in TNBC cells. Our
 findings implicate that EA flower extract may possess an important
 potential as an anticancer drug against TNBC. [Fouzat, Arij;

J Nouri, R; Schroeder, J; Champiri, BM; Akochakian, M Nouri, Reza; Schroeder, Jan; Champiri, Bahareh Mahmudieh; Akochakian, Mahdiah Effect of Six-Week Resistance Training with Thera-Band and Combined Training on Static and Dynamic Balance in Breast Cancer Survivors: A Randomized Clinical Controlled Trial MIDDLE EAST JOURNAL OF CANCER English Article

Resistance training; Core stability training; Breast cancer EXERCISE PROGRAM; POSTURAL CONTROL; WOMEN; ADULTS; REHABILITATION; INSTABILITY; PREVENTION; INJURY; ERROR; MODEL

Background: Balance impairment is related to breast cancer treatments, such as radiation therapy and chemotherapy. The aim of the present study was to investigate the effect of six-week resistance training with Thera-Band and combined training (training with Thera-Band and core stability training) on static and dynamic balance in breast cancer survivors. Methods: In this randomized controlled trail, we divided 75 patients with breast cancer into three groups: 1) resistance training group (n=25, age= 46 +/- 5.82, BMI= 25.7 +/- 3.9), combined training group, (n=25, age= 48.9 +/- 7.06, BMI 24.6 +/- 3.5), and control group (n=25, age= 46 +/- 7.15, BMI= 25.17 +/- 3.7). Afterwards, we employed Single leg standing and Balance Error Scoring System (BESS) to measure the static balance; Four Square Step Test (FSST) and Timed Up and Go (TUG) were further used for dynamic balance in pre- and post-test. Exercise program was performed by two training groups for six weeks and three sessions per week. Resistance training with Thera-Band group performed 13 resistance trainings with Them-Band. In combined group, resistance training was similar to Thera-Band group, but combined group were performed seven core stability trainings. We analyzed the data by two-way repeated measurements ANOVA using the software package SPSS V.22. Results: Results showed that there were no significant interaction effects indicating an exercise specific development, depending on the type of exercise or control condition $P>0.05$). Furthermore, there were no significant deference among the resistance training with Thera-Band, the combined exercise, and the control groups ($P>0.05$). Conclusion: It can be concluded that the six-week resistance training with Thera-Band and combined training (training with Thera-Band and core stability training) has no positive effects on static and dynamic balance in breast cancer survivors. We

recommend that more studies be conducted in this regard. Paclitaxel May Inhibit Epithelial-Mesenchymal Transition Properties of Triple-negative Breast Cancer Cell Line via Altering the Expression of EMT-promoting and -inhibiting MicroRNAs MIDDLE EAST JOURNAL OF CANCER English Article

Breast cancer; MiR-199a-5p; MiR-10b; Paclitaxel; Vimentin; MMP-9 E-CADHERIN; METASTASIS; INVASION Background: Abnormal expressions of microRNAs are related to various cancers such as breast cancer for which paclitaxel is widely used as a chemotherapeutic agent. We aimed to investigate the effect of paclitaxel treatment on the expression level of miR-199a-5p and miR-10b, involved in epithelial-mesenchymal transition (EMT) process in breast cancer cell lines. Methods: Human breast cancer cell lines BT-474, SKBR-3, MDA-MB-231, and MCF-7 were cultured and MTT assay was used to determine IC50 of paclitaxel. RNA was extracted, cDNA was synthesized, and the expression level of miRNAs and genes was quantitatively determined using real-time PCR. Results: After treatment with paclitaxel, the expression level of miR-199a-5p significantly decreased in MCF-7 and SKBR-3 cell lines, while it increased in MDAMB-231 and BT-474. The expression level of miR-10b was also significantly reduced in MCF-7, MDA-MB-231, and SKBR-3 and increased in BT-474 cell lines following treatment with paclitaxel. Our results further indicated that paclitaxel reduced the expression level of vimentin and MMP-9 in MDA-MB-231 cell line. Conclusion: Our findings revealed the increased expression of EMT-inhibitor miR-199a-5p and the decreased expression of metastamir miR-10b after treatment of MDA-MB-231 metastatic breast cancer cell line. Reduced expressions of vimentin and MMP-9 were also observed, corroborating the inhibition of metastasis markers in this type of breast cancer. The therapeutic effect of paclitaxel may in part be due to the change in the balance of EMT-promoting and EMT-inhibiting miRNAs.

 STRESS; CELLULAR SENESENCE; SEX-DIFFERENCES; COENZYME Q(10);
 ELDERLY-MEN; OLIVE-OIL; QUALITY; CONSUMPTION Colorectal cancer
 (CRC) is a major global health concern and represents a
 significant public health challenge in Hungary, where it exhibits
 some of the highest morbidity and mortality rates in the European
 Union. The Mediterranean diet has been suggested to reduce the
 incidence of CRC, but comprehensive evidence from diverse study
 designs is needed to substantiate this effect. A systematic
 literature search was conducted in PubMed, ClinicalTrials.gov,
 CENTRAL, and the Web of Science to identify randomized controlled
 trials and human clinical trials from 2008 to 2024 to identify
 relevant studies. Statistical analysis was performed using the
<https://metaanalysisonline.com> web application using a random
 effects model to estimate the pooled hazard rates (HRs). Forest
 plots, funnel plots, and Z-score plots were utilized to visualize
 results. We identified 15 clinical trials and 9 case-control
 studies, encompassing a total of 2,217,404 subjects. The pooled
 analysis indicated that adherence to the Mediterranean diet
 significantly reduced the prevalence of CRC (HR = 0.84, 95% CI =
 0.78-0.91, p < 0.01). This protective effect was consistent across
 sexes, with HRs of 0.85 (95% CI = 0.75-0.97, p = 0.01) for males
 and 0.88 (95% CI = 0.79-0.99, p = 0.03) for females. Case-control
 studies specifically showed a substantial effect (HR = 0.51, 95%
 CI = 0.38-0.68, p < 0.01). Notable heterogeneity was observed

across studies, yet the a priori information size was substantially below the cumulative sample size, ensuring sufficient data for reliable conclusions. The findings from this meta-analysis reinforce the protective role of the Mediterranean diet against CRC. The results of this meta-analysis will inform dietary interventions designed to mitigate CRC risk, which are conducted within the framework of the Semmelweis Study, an ongoing comprehensive cohort study at Semmelweis University, designed to explore the multifaceted causes of unhealthy aging in Hungary. These interventions aim to explore the practical application of Mediterranean dietary patterns in reducing CRC incidence among the Hungarian population. Association between epidemiological and clinico-pathological features of breast cancer with prognosis, family history, Ki-67 proliferation index and survival in Tunisian breast cancer patients PLOS ONE English Article

YOUNG AGE; MOLECULAR SUBTYPES; WOMEN; MANAGEMENT; DIAGNOSIS; MARKER; IMPACT; COMORBIDITIES; CARCINOMA; COHORT Breast cancer has different epidemio-clinical characteristics in Middle East and North-African populations compared to those reported in the Western countries. The aim of

this study is to analyze the epidemiological and clinico-pathological features of breast cancer in Tunisia and to determine prognostic factors with special interest to family history, Ki-67 proliferation index and comorbidity. We retrospectively reviewed epidemiological and clinicopathological data from patients' medical records, treated in the Medical Oncology Department at Abderrahmane Mami Hospital, in the period 2011-2015. Data has been collected on 602 breast cancer patients and analyzed using SPSS software V.23.0. Our study showed high fractions of young breast cancer patients and cases with dense breasts. The most prevalent comorbidities observed in the studied cohort were cardiovascular diseases and diabetes. Familial breast cancer was found in 23.3% of cases and was associated with younger age at diagnosis ($p < 0.001$) and advanced stage ($p = 0.015$). Ki-67 index $> 20\%$ was significantly associated with early age at diagnosis, lymph node involvement ($p = 0.002$), advanced tumor grade ($p < 0.001$) and high risk of relapse ($p = 0.007$). Ki-67 cut-off 30% predicted survival in luminal cases. Survival was worse in patients with triple negative breast cancer compared to non-triple negative breast cancer, inflammatory breast cancer compared to non-inflammatory breast cancer, moderately to poorly differentiated tumors compared to well-differentiated tumors and with positive lymph nodes compared to pN0 ($p < 0.05$). Our study showed new insights into epidemiological and clinico-pathological characteristics of breast cancer that are not well explored in Tunisian population. Considering our findings along with the implementation of electronic health record system may improve patient health care quality and disease management. A dietary pattern based on estrogen metabolism is associated
 with breast cancer risk in a prospective cohort of postmenopausal
 women INTERNATIONAL JOURNAL OF CANCER English

Article breast cancer;
 dietary pattern; estrogen metabolism; reduced rank regression
 ENDOGENOUS ESTROGENS; MEDITERRANEAN DIET; URINARY ESTROGENS;
 HEALTH; CONSUMPTION; MICROBIOME; NUTRITION Increased exposure to
 estrogen is a risk factor for postmenopausal breast cancer, and
 dietary factors can influence estrogen metabolism. However,
 studies of diet and breast cancer have been inconclusive. We
 developed a dietary pattern associated with levels of unconjugated
 estradiol and the ratio of 2- and 16-hydroxylated estrogen
 metabolites in a subsample of Prostate, Lung, Colorectal and
 Ovarian Screening Trial (PLCO) participants (n=653) using reduced
 rank regression, and examined its association with postmenopausal
 breast cancer prospectively in the larger PLCO cohort (n=27,488).
 The estrogen-related dietary pattern (ERDP) was comprised of foods
 with positively-weighted intakes (non-whole/refined grains,
 tomatoes, cruciferous vegetables, cheese, fish/shellfish high in -
 3 fatty acids, franks/luncheon meats) and negatively-weighted
 intakes (nuts/seeds, other vegetables, fish/shellfish low in -3
 fatty acids, yogurt, coffee). A 1-unit increase in the ERDP score
 was associated with an increase in total (HR: 1.09, 95% CI: 1.01-
 1.18), invasive (HR: 1.13; 95% CI: 1.04-1.24) and estrogen
 receptor (ER)-positive (HR: 1.13, 95% CI: 1.02-1.24) breast cancer
 risk after adjustment for confounders. Associations were observed
 for the fourth quartile of ERDP compared with the first quartile
 for overall breast cancer (HR: 1.14; 95% CI: 0.98-1.32), invasive
 cases (HR: 1.20, 95% CI: 1.02-1.42) and ER-positive cases (HR:
 1.19; 95% CI: 0.99-1.41). The increased risk associated with
 increasing ERDP score was more apparent in strata of some effect
 modifiers (postmenopausal hormone therapy non-users and non-obese
 participants) where the relative estrogen exposure due to that
 factor was lowest, although the p values for interaction were not
 statistically significant. Results suggest a dietary pattern based
 on estrogen metabolism is positively associated with
 postmenopausal breast cancer risk, possibly through an estrogenic
 influence. What's new? Serum levels of estrogen metabolites, which
 may be influenced by certain dietary factors, are associated with
 postmenopausal breast cancer risk. However, studies of diet and
 breast cancer have been inconclusive. In our study, an estrogen-
 related dietary pattern (ERDP) was developed based on data from
 dietary questionnaires and serum concentrations of estrogen
 metabolites in a subsample of control participants and cancer
 patients. The ERDP strongly correlated with the intake of refined

grains, cheese, lunch meats and yogurt. The ERDP was positively associated with postmenopausal breast cancer risk, with stronger effects in invasive and estrogen receptor-positive cases.

Kinase 1 Predicts Lymph Node Metastasis in Middle Eastern

Colorectal Cancer Patients; Its Inhibition Reverses 5-Fu

Resistance in Colorectal Cancer Cells CELLS English

Article PLK1; CRC; stemness;

EMT; Zeb1 PLK1; PHOSPHORYLATION; APOPTOSIS; INVASION; MARKER;

TARGET Polo-like kinase 1 (PLK1) is a serine/threonine-protein kinase essential for regulating multiple stages of cell cycle progression in mammals. Aberrant regulation of PLK1 has been observed in numerous human cancers and is linked to poor prognoses. However, its role in the pathogenesis of colorectal cancer (CRC) in the Middle East remains unexplored. PLK1 overexpression was noted in 60.3% (693/1149) of CRC cases and was significantly associated with aggressive clinico-pathological parameters and p-ERK1/2 overexpression. Intriguingly, multivariate logistic regression analysis identified PLK1 as an independent predictor of lymph node metastasis. Our in vitro experiments demonstrated that CRC cells with high PLK1 levels were resistant

to 5-Fu treatment, while those with low PLK1 expression were sensitive. To investigate PLK1 ' s role in chemoresistance, we used the specific inhibitor volasertib, which effectively reversed 5-Fu resistance. Interestingly, forced PLK1 expression activated the CRAF-MEK-ERK signaling cascade, while its inhibition suppressed this cascade. PLK1 knockdown reduced epithelial-to-mesenchymal transition (EMT) progression and stem cell-like traits in 5-Fu-resistant cells, implicating PLK1 in EMT induction and stemness in CRC. Moreover, silencing ERK1/2 significantly mitigated chemoresistance, EMT, and stemness properties in CRC cell lines that express PLK1. Furthermore, the knockdown of Zeb1 attenuated EMT and stemness, suggesting a possible link between EMT activation and the maintenance of stemness in CRC. Our findings underscore the pivotal role of PLK1 in mediating chemoresistance and suggest that PLK1 inhibition may represent a potential therapeutic strategy for the management of aggressive colorectal cancer subtypes.  gamma-1 phosphorylation status is prognostic of metastatic risk in
 patients with early-stage Luminal-A and -B breast cancer subtypes
 BMC CANCER English Article

Breast cancer; Phospholipase C gamma 1;
 Prognosis; Luminal subtypes; Menopausal status INTERNATIONAL
 EXPERT CONSENSUS; UNFOLDED PROTEIN RESPONSE; PHOSPHOLIPASE C-
 GAMMA-1; ESTROGEN-RECEPTOR; PRIMARY THERAPY; CYTOSKELETON;
 HIGHLIGHTS; SURVIVAL BackgroundPhospholipase C gamma 1 (PLC
 gamma 1) is highly expressed in human tumours. Our previous

studies reported that both stable and inducible PLC gamma 1 down-regulation can inhibit formation of breast-cancer-derived experimental lung metastasis. Further, high expression of PLC gamma 1 and its constitutively activated forms (i.e., PLC gamma 1-pY1253, PLC gamma 1-pY783) is associated with worse clinical outcome in terms of incidence of distant metastases, but not of local relapse in T1-T2, N0 breast cancer patients. Methods In the present retrospective study, we analysed the prognostic role of PLC gamma 1 in early breast cancer patients stratified according to the St. Gallen criteria and to their menopausal status. PLC gamma 1-pY1253 and PLC gamma 1-pY783 protein expression levels were determined by immunohistochemistry on tissue microarrays, and were correlated with patients' clinical data, using univariate and multivariate statistical analyses. Results In our series, the prognostic value of PLC gamma 1 overexpression was restricted to Luminal type tumours. From multivariate analyses, pY1253-PLC gamma 1 (High) was an independent prognostic factor only in postmenopausal patients with Luminal-B tumours (hazard ratio [HR], 2.4; 95% confidence interval [CI], 1.1-5.3; P=0.034). Conversely, PLC gamma 1-pY783 (High) was a remarkably strong risk factor (HR, 20.1; 95% CI, 2.2-178.4; P=0.003) for pre/perimenopausal patients with Luminal-A tumours. Conclusions PLC gamma 1 overexpression is a strong predictive surrogate marker of development of metastases in early Luminal-A and -B breast cancer patients, being able to discriminate patients with high and low risk of metastases. Therefore, targeting the PLC gamma 1 pathway can be considered of potential benefit for prevention of metastatic disease.

Elevated Serum Tumor Markers Carcinoembryonic Antigen (CEA) and
Cancer Antigen 15-3 (CA15- 3) among Patients with Different
Subtypes of Metastatic Breast Cancer MIDDLE EAST JOURNAL OF
CANCER English Article

Breast cancer; Metastasis; Cancer antigen 15-3 (CA15-3); Carcinoembryonic antigen (CEA) CLINICOPATHOLOGICAL
PARAMETERS; MOLECULAR SUBTYPES Background: Cancer antigen 15-3
and carcinoembryonic antigen are used in clinical and laboratory
diagnosis of metastatic breast cancer. Previous studies have noted
conflicting results about the association between carcinoembryonic
antigen and cancer antigen 15-3 in metastatic breast cancer. The
present study examined serum tumor marker levels of
carcinoembryonic antigen and cancer antigen 15-3 among patients
with different subtypes of metastatic breast cancer. Methods: In
this cross-sectional study, we assessed metastatic breast cancer
patients diagnosed between 2005 and 2012 who referred to academic
Hospitals affiliated with Mashhad University of Medical Sciences.
The patients were selected by systematic randomization sampling.
Demographic, clinical, pathological, and therapeutic data were
collected from patients' hospital records. Statistical analyses
were performed by Statistical Package for the Social Sciences
version 16.0 software. Results: A total of 298 eligible patients
enrolled in the study. Patients' median age was 48.39 +/- 12.57
years. Elevated serum levels of carcinoembryonic antigen were
identified in 65.17% of patients and cancer antigen 15-3 in 57.29%
of patients. Based on molecular subtype categorization, 109
(39.5%) patients were human epidermal growth factor receptor 2
negative and 105 (38.0%) patients were in the luminal group. There
was no significant correlation between serum carcinoembryonic
antigen and cancer antigen 15-3 with subtypes of the tumor. The
most common sites for metastasis were bones and liver,
respectively. However, there was no significant correlation
between serum carcinoembryonic antigen and cancer antigen 15-3
with the site of metastasis. There was a significant association
between serum carcinoembryonic antigen level and stages IIA and
IV. Conclusion: One of the most significant findings of the
current study was the increased serum carcinoembryonic antigen and
cancer antigen 15-3 levels in most metastatic breast cancer
participants. We postulate that regular measurement of serum
cancer antigen 15-3 and carcinoembryonic antigen could be useful
for earlier detection and prediction of outcomes. [Taghizadeh,

Moudatsou, Maria; Vouyiouka, Panayiota; Karagianni-Hatziskou, Eleni; Rovithis, Michael; Stavropoulou, Areti; Koukouli, Sofia Knowledge and Use of Cervical Cancer Prevention Services among Social Work and Nursing University Students HEALTHCARE English Article

cervical cancer prevention services; knowledge; social capital; social work students; nursing students; health education HUMAN-PAPILLOMAVIRUS; BREAST; INFECTION; LATINAS

The present study examines: (a) the knowledge of healthcare students on cervical cancer (CC) issues and the use of related preventive services, as well as their association with the field of study and other sociodemographic characteristics; (b) the possible effect of social capital and its parameters. A cross-sectional study was conducted, using a convenience non-probability sampling technique. The final sample consisted of forty-nine social work and fifty-one nursing students. The two groups were similar regarding their sociodemographic characteristics and the knowledge and use of gynecological preventive services. However, the nursing students undertook a PAP smear check-up to a lesser extent (48.6%) compared to social work students (51.4%) ($p = 0.026$). The social capital scores were high for both groups, but social work students were significantly more 'Tolerant to diversity'. For the total sample, only the 'Family and friends connections' subscale correlated with knowledge about the existing gynecological preventive services. Among the main reasons explaining university students' avoidance of preventive testing were the feelings of fear and embarrassment associated with the PAP smear test. Given the significance of the future professional

roles of healthcare students as information sources and leaders in women's CC preventive behavior, understanding the individual factors contributing to their own adherence is essential. It is equally important to increase their scientific knowledge through the improvement of academic curricula regarding these issues.

Squalene protects against oxidative DNA damage in MCF10A human mammary epithelial cells but not in MCF7 and MDA-MB-231 human breast cancer cells FOOD AND CHEMICAL TOXICOLOGY

English Article

Squalene; Human breast cancer; Comet assay; Virgin olive oil; Cancer prevention VIRGIN OLIVE OIL; CHEMOPREVENTIVE AGENT; BONE-MARROW; IN-VITRO; CARCINOGENESIS; GROWTH; ASSAY; ANTIOXIDANTS; INHIBITION; PREVENTION Until now, very little has been known about the antioxidant capacity of squalene and its effect on human breast tumourigenesis. In the present work, we investigated squalene's scavenging properties and its effect on cell proliferation, cell cycle profile, apoptosis, reactive oxygen species (ROS) level and oxidative DNA damage, using human breast cell lines. Our results showed that squalene neither possesses

scavenging activity nor significantly alters cell proliferation rates, the cell cycle profile or cell apoptosis in human mammary epithelial cells (MCF10A), minimally invasive (MDA-MB-231) breast cancer cells, and highly invasive (MCF7) breast cancer cells. However, we found that squalene did exert the following effects on MCF10A epithelial cells in a dose-dependent manner: (a) it decreased intracellular ROS level, (b) it prevented H2O2-induced oxidative injury, and (c) it protected against oxidative DNA damage. Interestingly, squalene did not exert these effects on MCF7 and MDA-MB-231 cancer cells. Therefore, our data suggest that squalene, found in high amounts in virgin olive oils, could be partially responsible for the lower incidence of breast cancer in populations that consume the Mediterranean diet due to its protective activity against oxidative DNA damage in normal mammary cells. Knowledge, Attitude and Practice of School Nurses in the United Arab Emirates about HPV Infection and Vaccine

ASIAN PACIFIC JOURNAL OF CANCER PREVENTION

English Article

HPV

vaccine; cervical cancer; school nurses; United Arab Emirates, Abu Dhabi HUMAN-PAPILLOMAVIRUS INFECTION; CERVICAL-CANCER; UNIVERSITY; WOMEN Background: In 2008, the Health Authority in Abu Dhabi (the capital of the United Arab Emirates) introduced HPV vaccine free of charge for high school girls entering grade 11, becoming the

first state in the Middle East to do so. The objectives of this study were to assess the knowledge, attitude and practice of school nurses in the Emirate of Abu Dhabi about HPV infection and the vaccine. Materials and Methods: A quantitative study was designed and conducted from June to August 2012 in Emirate of Abu Dhabi. Data were collected through direct face to face interviews. from one hundred and twenty five nurses. Results: Knowledge of HPV infection and HPV vaccine was almost universal among the school nurses (97%). The majority of the participants (71%) thought that the HPV vaccine was good. Cultural unacceptability (45%) and lack of women's concern about their own health (21%) were rated as the top barriers for the successful introduction of the vaccine in the UAE. More than half of the sampled nurses (58%) have either given this vaccine to school girls or taken it themselves. The majority (95%) did not come across any side effects from the vaccine. The level of qualification and the place of work did not significantly affect the correct knowledge of HPV infection or cervical cancer prevention methods. Conclusions: The knowledge and attitude of the sampled school nurses in Abu Dhabi State about HPV infection and vaccine is very good in both the public and private sectors. However, a knowledge gap in cervical cancer screening methods was identified. Melatonin Supplementation on Cancer-Related Fatigue during
Chemotherapy Treatment of Breast Cancer Patients: A Double-Blind,
Randomized Controlled Study CANCERS English

Article melatonin;
supplement; cancer-related fatigue; breast cancer; chemotherapy
MEDITERRANEAN DIET; SLEEP DISORDERS; TRIAL; DISTURBANCES;
MANAGEMENT; QUALITY; WEIGHT; DRUGS; WOMEN Cancer-related
fatigue (CRF) is a common distressing complaint of breast cancer
(BC) patients treated with chemotherapy. Nutritional quality plays
a pivotal role in CRF, while increased interest towards new
pharmacological agents has been observed. Melatonin, an endogenous
hormone that regulates the human sleep-wake cycle, could alleviate
CRF. In the present randomized, placebo-controlled 3-month trial,

we investigated the effects of melatonin intake (i.e., 1 mg/day) vs. placebo in BC patients on CRF. In both arms, the Mediterranean diet (MD) was implemented. Medical history, anthropometry and blood withdrawal were performed. CRF was evaluated by the Functional Assessment of Chronic Illness Therapy-Fatigue questionnaire and MD adherence by the MedDietScore. In total, 49 BC women (median age 52 years) were recruited, namely N = 23 in the intervention arm and N = 26 in the placebo arm. At baseline, CRF was positively associated with body mass index (BMI), even when adjusted for age, waist circumference and blood indices related to disease prognosis ($\beta = -0.882$, $p = 0.003$). At 3 months, both groups showed a BMI decrease ($p < 0.05$), but only the intervention group improved CRF compared to baseline ($p = 0.003$). No differences in CRF were observed between the groups. In conclusion, melatonin oral supplementation could ameliorate CRF in BC patients.

Oleuropein Induces Cytotoxicity and Peroxiredoxin Over-expression in MCF-7 Human Breast Cancer Cells ANTICANCER RESEARCH English Article

Breast cancer; MCF-7; oleuropein; olive leaf; peroxiredoxin Background/Aim: As a fundamental staple of the Mediterranean diet, olive oil has long been recognized for its health benefits, including its ability to reduce cardiovascular and neurological disease. Oleuropein is the primary phenolic chemical found in all parts of the olive tree, especially in the leaves and fruit. Oleuropein exhibits anti-inflammatory and antioxidant properties, and has been associated with cancer inhibition in various animal and cell models. We investigated the effects of oleuropein on the MCF-7 human breast cancer cell line, and compared it to the non-cancerous MCF-10A breast epithelial line. Materials and Methods: Both cell lines were treated with two

different concentrations of oleuropein for 48 and 72 hours. Cytotoxicity, apoptosis, and peroxiredoxin expression were measured. Results: Forty-eight hours of oleuropein treatment induced cytotoxicity in MCF-7 cells, whereas it had no effect on MCF-10A cells. Furthermore, oleuropein-induced cytotoxicity in MCF-7 cells involved a measurable increase in apoptosis. Oleuropein treatment of MCF-7 cells significantly and dramatically increased expression of all six peroxiredoxin mRNAs (Prdx1-Prdx6), whereas oleuropein treatment of MCF-10A cells resulted in only a small increase in Prdx1 and Prdx6 expression, with no change in the expression of the other peroxiredoxins. Together, these data demonstrate differential susceptibility to oleuropein-induced cell death between the two lines, and differential regulation of peroxiredoxins. Conclusion: Oleuropein-induced over-expression of peroxiredoxins in MCF-7 cells may either facilitate its cancer-specific cytotoxicity or, alternatively, is a consequence of an altered response of cancer cells. DEDiCa Study Grp Baseline Association between Healthy Eating Index-2015 and Health-Related Quality of Life in Breast Cancer Patients Enrolled in a Randomized Trial Cancers

English Article healthy eating index; diet quality; health-related quality of life; breast cancer survivors DIET QUALITY; EORTC QLQ-C30; SURVIVORS;

COMORBIDITIES; ONCOLOGISTS; PREVALENCE; DEPRESSION; EXERCISE; FATIGUE; PROGRAM Simple Summary Quality of life significantly affects health outcomes in cancer patients. However, evidence of an association between diet quality and quality of life in cancer survivors is sparse in Mediterranean countries. The aim of this study was to evaluate the associations between an a priori diet quality index, the Healthy Eating Index-2015 (HEI-2015), and quality of life, assessed through a validated questionnaire targeted at women with a breast cancer diagnosis. A higher HEI-2015 score was positively associated with summary quality of life score and inversely associated with symptom scores.

Abstract

Health-related quality of life (HRQoL) represents one of the most concerning aspects for cancer patients. The Healthy Eating Index (HEI) is an a priori diet quality index directly associated with health outcomes and HRQoL in cancer survivors in North American populations. We evaluated, in a Mediterranean population, the baseline associations between HEI-2015 and HRQoL in 492 women with breast cancer recruited in a DEDiCa lifestyle trial. Dietary data were obtained from 7-day food records; HRQoL was assessed through the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ C30) and the C30 Summary Score (SumSc). Analysis of variance and multivariable linear and log-gamma regression models were performed. Mean and standard deviation for HEI-2015 score was 68.8 +/- 11.2; SumSc was 81.5 +/- 12.9. Women with lower HEI-2015 score had higher BMI, were more frequently exposed to tobacco smoke and had fewer years of education. Patients with a HEI-2015 score greater than 68.7 (median value) showed a significant increase in SumSc of 4% (p = 0.02). HEI-2015 components also associated with SumSc were beans and greens (beta = 1.04; p = 0.02). Weak associations were found for total vegetables and saturated fats. Higher diet quality in breast cancer survivors was associated with higher overall HRQoL in this cross-sectional analysis.

COLORECTAL CANCER IN PATIENTS WITH TYPE 2
DIABETES MELLITUS: A SINGLE-CENTER EXPERIENCE JOURNAL OF

colorectal cancer; anti-diabetic drugs GROWTH-FACTOR; INSULIN; RISK; COHORT Type 2 diabetes mellitus (T2DM) is associated with an increased risk of colorectal cancer (CRC). The aim of the study is to evaluate the prevalence of CRC in a cohort of Caucasian patients with T2DM and the association with other variables previously known to be related with increased risk of CRC. We retrospectively evaluated the data of 741 consecutive Caucasian patients with T2DM who underwent colonoscopic screening in our tertiary referral center. A control cohort of 333 patients with thyroid disease was selected to evaluate the difference in the incidence of CRC. At a median follow-up of 132.5 months (range 33.3-175.7), 67 cases of cancer (prevalence 9%) occurred; among these, 14 cases of CRC were reported (prevalence 1.88%) among the diabetic patients, while only two case (one of these was a CRC) (overall prevalence 0.006%, prevalence of CRC 0.003%) occurred in the control group; the difference between the prevalence of CRC was statistically significant (chi-square 4.21, $p = 0.04$). The median duration of T2DM to CRC diagnosis was 168 months (range 12-768). At the univariate analysis, older age ($p = 0.001$, $r = 0.138$) and diabetes duration ($p = 0.001$, $r = 0.138$) were related to higher risk of cancer, while metformin seems to be protective towards cancer ($p = 0.07$, $r = -0.098$). In the subset of patients with CRC, the age (RR = 2.25; 95% CI: 0.30 - 17.31; $p < 0.001$), the diabetes duration (RR = 1.93; 95% CI: 0.25 - 14.77; $p = 0.001$) and the sulphonylureas treatment (RR = 2.33; 95% CI: 0.78 - 7.38; $p = 0.007$) were independently correlated with CRC. In our study, the prevalence of CRC in the cohort of patients with T2DM was higher compared to that from the National Tumor Register in 2010 (0.5%). Furthermore, we could speculate that sulphonylureas may play a role in CRC carcinogenesis impairing the physiological insulin secretion. cancer MEDITERRANEAN DIET; ANTIOXIDANT; MODULATION;
ACTIVATION; UNDERLIES; SURVIVAL; PHENOLS; GROWTH; RICH

Oleuropein (OL) and hydroxytyrosol (HT), the main olive oil polyphenols, possess anti-proliferative effects in vitro. Fatty acid synthase, a key anabolic enzyme of biosynthesis of fatty acids, plays an important role in colon carcinoma development. Our aim was to investigate whether gene expression of FAS, as well as its enzymatic activity, is regulated by HT and OL in two human colon cancer cell lines, as HT-29 and SW620. In addition, we investigated the effects of these polyphenols on growth and apoptosis in these cells. FAS gene expression and activity in treated HT-29 and SW620 cells were evaluated by real-time PCR and radiochemical assay, respectively. Cell growth and apoptosis, after polyphenols treatment, were measured by MTT test and flow cytometry, respectively. The inhibition of proliferation, detected after HT treatment, was mediated by an inhibition of FAS expression and its enzymatic activity in SW620 cells, while the anti-proliferative effect in HT-29 cells seems to be independent from FAS. OL exerted an anti-proliferative effect only on SW620 cells with a mechanism which excluded FAS. Olive oil polyphenols used were able to induce apoptosis in both cell lines studied. The increase of apoptosis in these cells was accompanied by the block of cell cycle in the S phase. This study demonstrates that HT and OL may induce anti-proliferative and pro-apoptotic effects only in certain human colorectal cancer cell types. These effects are FAS mediated only in SW620 cells after treatment with HT.

Molecular docking, MMGBSA, and ADMET studies of phytoconstituents of *Ocimum gratissimum* on multiple breast cancer targets NATURAL PRODUCT RESEARCH English

Article; Early Access Ocimum gratissimum; breast cancer; EGFR; HER2; PI3K; binding affinity; pharmacokinetics APOPTOSIS; CARCINOMA; CELLS; INHIBITION; ISOVITEXIN; EXTRACT; GROWTH; ACID O. gratissimum is one of the most common medicinal plants in every community in Nigeria. This plant has been presumed to be useful in the management of diseases including breast cancer, which is one the commonest cancers affecting women globally. Hence, this study aimed to computationally investigate the phytochemicals present in O. gratissimum by elucidate their binding dynamics against five selected molecular targets of breast cancer and predict their pharmacokinetics properties. Molecular docking, MMGBSA calculation and ADMET prediction were used. The results showed that isovitexin has the highest binding affinity of -9.11 kcal/mol and -9.80 kcal/mol for Human Epidermal Growth Factor Receptor 2 (HER2) and Epidermal Growth Factor Receptor (EGFR) respectively. Rosmarinic acid has the highest binding affinity of -12.15 kcal/mol for Phosphatidylinositol 3-kinase (PI3K), Nepetoidin A has the highest binding affinity of -9.14 kcal/mol for oestrogen receptor (ER), and Vitexin has the highest binding affinity of -12.90 kcal/mol for Progesterone receptor (PR). MMGBSA provided total binding energy that confirmed the stability of the complexes under physiological conditions. The ADMET profiles showed that O. gratissimum top phytochemicals identified would be safe for oral administration with no hepatotoxicity. Overall, this study identified isovitexin, vitexin, rosmarinic acid, nepetoidin A and luteolin among others, as compounds that exhibit strong anti-cancer properties against breast cancer cells. Cancer Recurrence and Survival: The Pathways Study JNCI CANCER
SPECTRUM English Article

MEDITERRANEAN DIET; ADHERENCE; WOMEN; RISK;
DIAGNOSIS; NUTRITION; MORTALITY; PATTERNS; THERAPY; DISEASE

Background: Prior research suggests a relationship between overall diet quality and breast cancer survival, although few studies have reported on this topic. We evaluated whether 4 dietary quality indices consistent with healthy eating recommendations around the time of breast cancer diagnosis were associated with risk of recurrence, cause-specific, and all-cause mortality. Methods: A total of 3660 women diagnosed with invasive breast cancer were included. Diet was assessed an average of 2.3 (range = 0.7-18.7) months after diagnosis, from which 4 dietary quality indices were derived: the American Cancer Society guidelines (ACS), the alternate Mediterranean Diet Index (aMED), the Dietary Approaches to Stop Hypertension (DASH), and the 2015 Healthy Eating Index (HEI). Over 40 888 person-years of follow-up, 461 breast cancer recurrences, and 655 deaths were ascertained. Cox models were used to estimate hazards ratios (HRs) and 95% confidence intervals (CIs). Results: Adjusted comparisons between extreme quintiles showed all 4 dietary quality indices to be inversely associated with all-cause mortality, suggesting a 21%-27% lower risk (ACS HR = 0.73, 95% CI = 0.56 to 0.95; aMED HR = 0.79, 95% CI = 0.61 to 1.03; DASH HR = 0.76, 95% CI = 0.58 to

1.00; HEI HR = 0.77, 95% CI = 0.60 to 1.01). Similar patterns were noted for non-breast cancer mortality (ACS HR = 0.69, 95% CI = 0.48 to 0.98; aMED HR = 0.73, 95% CI = 0.50 to 1.05; DASH HR = 0.55, 95% CI = 0.38 to 0.79; HEI HR = 0.67, 95% CI = 0.48 to 0.94). None of the dietary quality indices were associated with recurrence or breast cancer-specific mortality. Conclusion: Food intake patterns concordant with dietary quality indices consistent with recommendations for healthy eating may be beneficial for women with breast cancer. J Vecchio, A; Anzidei, M; Serpelloni, E
Vecchio, A.; Anzidei, M.; Serpelloni, E. Sea
level rise projections up to 2150 in the northern Mediterranean
coasts ENVIRONMENTAL RESEARCH LETTERS English
Article Mediterranean sea;
sea level rise projections; vertical land movements LAND
SUBSIDENCE; DEFORMATION; SCENARIOS; VELOCITY; MECHANISMS; DELTAS;
RATES; FIELD Vertical land movements (VLM) play a crucial role

in affecting the sea level rise along the coasts. They need to be estimated and included in the analysis for more accurate Sea Level (SL) projections. Here we focus on the Mediterranean basin characterized by spatially variable rates of VLM that affect the future SL along the coasts. To estimate the VLM rates we used geodetic data from continuous global navigation satellite system stations with time series longer than 4.5 years in the 1996-2023 interval, belonging to Euro-Mediterranean networks and located within 5 km from the coast. Revised SL projections up to the year 2150 are provided at 265 points on a geographical grid and at the locations of 51 tide gauges of the Permanent Service for Mean Sea Level, by including the estimated VLM in the SL projections released by the Intergovernmental Panel on Climate Change (IPCC) in the AR6 Report. Results show that the IPCC projections underestimate future SL along the coasts of the Mediterranean Sea since the effects of tectonics and other local factors were not properly considered. Here we show that revised SL projections at 2100, when compared to the IPCC, show a maximum and minimum differences of 1094 +/- 103 mm and -773 +/- 106 mm, respectively, with an average value that exceeds by about 80 mm that of the IPCC in the reference Shared Socio-economic Pathways and different global warming levels. Finally, the projections indicate that about 19.000 km² of the considered Mediterranean coasts will be more exposed to risk of inundation for the next decades, leading to enhanced impacts on the environment, human activities and infrastructures, thus suggesting the need for concrete actions to support vulnerable populations to adapt to the expected SL rise and coastal hazards by the end of this century. Brown, Robert; Kerr, Karen; Haoudi, Abdelali; Darzi, Ara
Tackling cancer burden in the Middle East: Qatar as an
example LANCET ONCOLOGY English Article

BREAST-CANCER; LOW-RESOURCE;
MANAGEMENT; COUNTRIES; CONSENSUS; CARE Cancer prevalence is
increasing in the Middle East, partly because of increased life
expectancy and adoption of western lifestyle habits. Suboptimum
delivery of health care also contributes to late diagnosis and
poor survival of people with cancer. Public awareness of cancer
risk is frequently low and misconceptions high, thereby preventing
patients from seeking treatment early and constituting a
substantial barrier to improvement of cancer outcomes. Screening
programmes might have low uptake in Arab populations because of
social and health beliefs about cancer. This review outlines the
opportunities available to Middle Eastern countries and their
emerging economies to learn from global experiences in cancer
care, service provision, and research partnerships. The Middle
East has begun to develop several health-care transformation
programmes. Qatar, in particular, has published a National Health
Strategy, in which cancer is one of the main commitments; this
Strategy provides the focus of this review. The development of
effective health-care strategies and evidence-based medicine
directly linked to innovative cancer research is needed to improve
cancer care. Although the full extent of the proposed solutions
are not necessarily implementable in all Middle Eastern countries,
wealthy states can lead derivation of population-specific
approaches that could have effects throughout the region. Key
challenges are outlined-namely, human capacity and training,
subspecialisation of services, building on international cancer
research initiatives, and the need for earlier diagnosis and
awareness in the population. Countries in the Gulf Region (ie,
countries bordering the Persian Gulf, including Iran, Iraq,
Kuwait, Saudi Arabia, Bahrain, Qatar, UAE, and Oman) need to
address these challenges to be at the forefront of integrated
cancer care and research and ensure that the latest innovations
and best possible care are delivered to their populations.

J Xie, W; Zuo, J; Ma, Z; Yu, W; Hu, Z; Yang, TS; Song, ZS
Xie, W.; Zuo, J.; Ma, Z.; Yu, W.; Hu, Z.; Yang,
Tingsong; Song, Zhenshun The Burden of Colorectal
Cancer Attributable to Diet Low in Fiber from 1990 to 2019: A
Global, Regional and National Analysis JOURNAL OF NUTRITION
HEALTH & AGING English Article
Colorectal cancer; death; diet low in fiber;
disability-adjusted life-year; global burden of disease study
UNITED-STATES; TRENDS Objectives The colorectal cancer (CRC)
burden is increasingly high. The aim of this study was to
investigate temporal and geographical trends in CRC deaths and
disability-adjusted life-years (DALYs) attributable to diet low in
fiber globally from 1990 to 2019. Design Cross-sectional study.
Setting The study based on the Global Burden of Disease Study
(GBD) 2019. Participants The population comprised individuals from
204 countries and territories who were diagnosed with CRC
attributable to diet low in fiber from 1990 to 2019. Measurements
Deaths, DALYs, age-standardized mortality rates (ASMR), and age-
standardized DALY rates (ASDR) for CRC attributable to diet low in
fiber were described, and estimated annual percentage change
(EAPC) was further calculated to assess the burden in different
regions, countries, sexes, and age groups. Additionally, we
explored the association between EAPC and ASMR/ASDR (in 1990) and
Human Development Index (HDI, in 2019). Results From 1990 to 2019,
global ASMR and ASDR for CRC attributable to diet low in fiber
decreased slightly, but the corresponding deaths and DALYs
increased by 63.37% and 51.36%, respectively. Those burden varied
considerably between regions and countries. The burden was higher
in high, high-middle and middle SDI regions, especially in Asia
and Western Europe, but when HDI > 0.7, an increasingly rapid
decline in ASMR and ASDR was revealed. Unexpectedly, many less
well-developed countries within the traditionally low deaths and
DALYs regions of Africa, Central Latin America, and Middle East
showed gradual increases in ASMR and ASDR. Conclusion The global
burden of CRC attributable to diet low in fiber has decreased over
the last 30 years, but remains at a high level. It is essential
for decision-makers to take targeted measures for improving
population awareness and intake of dietary fiber. [Xie, W.; Zuo,

Frequency of Germ-Line BRCA1 Mutations among Spanish

Families from a Mediterranean Area HUMAN MUTATION

English Article BRCA1;

breast cancer; CSGE; mutation screening We have carried out a
study of breast cancer in Spanish families in which the entire
coding region of the BRCA1 gene have been analyzed. To identify
BRCA1 mutations, PTT and CSGE methods were used followed by direct
sequencing. We investigated 51 breast cancer women with a family
history. Among these we have identified 7 frameshifts mutations
(15%), 185delAG (4 times), 1623del5 and 3450del4 (2 times), and 3
missense mutations, Ser1613Gly, Met1652Ile and Ala1708Glu, which
are likely polymorphisms. These findings show that BRCA1 is
implicated in a fraction of Spanish familial breast cancer similar
to other countries. There was association between bilateral breast
cancer and BRCA1 mutations. The CSGE technique has been
demonstrated to be a highly reliable method for mutation screening
because of its sensitivity and high throughput. (C) 2000Wiley-

Prevalence of Systemic Rheumatic Diseases Among Breast Cancer
Patients and Its Relationship With Survival ARCHIVES OF

RHEUMATOLOGY English Article

Breast cancer; prevalence; survival; systemic

rheumatic diseases IN-SITU; CYTOKINES; ESTROGEN; TUMORS; RISK

Objectives: This study aims to investigate the prevalence of systemic rheumatic diseases (SRDs) among patients with breast cancer (BC) and to identify the clinicopathological characteristics of these patients. **Patients and methods:** A total of 3,744 female patients with BC (mean age 49 +/- 11.7 years; range, 18 to 92 years) followed in Hacettepe University Faculty of Medicine, Medical Oncology Department between January 2006 and December 2015 were retrospectively assessed. Patients with or without SRD were compared in terms of clinicopathological features including age, menopausal state, smoking status, body mass index (BMI), age of menarche, age at first labor, and number of children. The groups were also evaluated regarding tumor grade, stage, estrogen receptor and progesterone receptor expression, human epidermal growth factor receptor 2 overexpression, and survival. **Results:** Of the patients analyzed, 68 (1.81%) had concomitant SRD. Among these patients, 33 (48.6%) had rheumatoid arthritis, eight (11.8%) had familial Mediterranean fever, eight (11.8%) had Behcet's disease, four (5.8%) had Sjogren's syndrome, four (5.8%) had systemic lupus erythematosus, six (8.8%) had ankylosing spondylitis, three (4.4%) had systemic sclerosis, one (1.4%) had polymyositis, and one (1.4%) had temporal arteritis. The groups with or without SRDs were similar in terms of age, smoking status, BMI, menopausal state, breast feeding duration, age at menarche and first birth. Stage 1 and 2 BC was more prevalent in SRD patients (74.6% vs. 64.5%, p=0.018). The rate to receive chemotherapy was significantly lower in patients with SRD. However, there was no significant difference in five-year overall survival rates between patients with or without SRD. **Conclusion:** Among patients with BC, 1.81% had concomitant SRD. These patients were diagnosed at early stages and given chemotherapy less frequently. However, they had similar survival rates compared to those without SRDs. J Ghosh, SK; Bera, T; Pal, S Ghosh, Swapan
Kumar; Bera, Tanmay; Pal, Sujoy Antiproliferative,
Apoptotic, and Antimigration Property of Ethyl Acetate Extract of
Calocybe indica against HeLa and CaSki Cell Lines of Cervical

Mushroom; Cervical cancer; Cytotoxicity;
Apoptosis; Metastasis; Bioactive compounds INHIBITS
PROLIFERATION; MEDICINAL MUSHROOMS; HUMAN BREAST; CYCLE; GROWTH;
ANTICANCER; ANTITUMOR; ARREST; SUBSTANCES; ACTIVATION

Background: The incidence rate of cervical cancer is increasing and its existing drugs are becoming more and more resistant. Therefore, we extracted the fruiting body of *Calocybe indica* edible mushroom in 90% ethyl acetate extract (EAE) and evaluated it as an anticancer property against HeLa and CaSki. Method: We performed cytotoxicity assay by MTT, cell morphological study by phase contrast microscope, and apoptosis study by nuclear morphology via DAPI staining under inverted microscopy; the expressions of proapoptotic and antiapoptotic genes and p53 were examined by Western blotting, cell cycle analysis, and cologenic and cell migration assay. Antioxidant content and activity assays were performed and for mycochemistry analysis of EAE, thin layer chromatography (TLC) was done. Results: EAE-treated HeLa and CaSki cells became round and showed condensed and fragmented nuclei. They inhibited the cell proliferation of both cancer cell lines in a dose-dependent manner. At maximum dose (1250 μ g/mL) after 24 h, the cell inhibition percentages of HeLa and CaSki cells were 97.12 $\pm$ 10.01 and 98.52 $\pm$ 10.08 ($P < 0.05$), respectively. They upregulated the expression of p53, caspase 3, and caspase 9 while down-regulating Bcl2 gene. Cell cycle became arrested at G2/M checkpoint of both cancer cell lines by EAE. EAE inhibited colony formation and cell migration. The antioxidant assay showed that EAE contained good amounts of phenolic compounds, flavonoids, and ascorbic acids and had good antioxidant activity. TLC supported the presence of bioactive components. Conclusion: The EAE of *C. indica* exerts very potent anticervical cancer effects. It is urgent that future studies analyze its bioactive compounds in detail and examine them in animal models. Giacomo!Castelvetro's salads.: Anti-HER2 oncogene
nutraceuticals since the 17th century? CLINICAL & TRANSLATIONAL
ONCOLOGY English Article

olive oil; HER2; Mediterranean diet; breast cancer;
oleic acid; polyphenols BREAST-CANCER CELLS; MONOUNSATURATED
FATTY-ACID; MEDITERRANEAN DIETARY TRADITIONS; VIRGIN OLIVE OIL;
OLEIC-ACID; TRASTUZUMAB HERCEPTIN(TM); EXPRESSION; OVEREXPRESSION;
AMPLIFICATION; NUTRIGENOMICSWe are accumulating evidence to
suggest that 17th century Renaissance foodways-largely based on
the old "Mediterranean dietary traditions"-may provide new
nutraceutical management strategies against HER2-positive breast
cancer disease in the 21st century. Epidemiological and
experimental studies begin to support the notion that "The Sacred
Law of Salads" (i.e., "raw vegetables. plenty of generous (olive)
oil")-originally proposed in 1614 by Giacomo Castelvetro in its
book The Fruit, Herbs & Vegetables of Italy -might be considered
the first (unintended) example of customised diets for breast
cancer prevention based on individual genetic make-up (i.e.,
nutraceuticals against human breast carcinomas bearing HER2
oncogene amplification/overexpression). First, the so-called salad
vegetables dietary pattern (i.e., a high consumption of raw
vegetables and olive oil) appears to exert a protective effect
mostly confined to the HER2-positive breast cancer subtype, with
no significant influence on the occurrence of HER2-negative breast
cancers. Second, all the main olive oil constituents (i.e., the
omega-9 monounsaturated fatty acid oleic acid and polyphenolic
compounds such as the secoiridoid oleuropein or the lignan 1-[+]-
acetoxypinoresinol] dramatically reduce HER2 expression and
specifically induce apoptotic cell death in cultured HER2-positive
breast cancer cells, with marginal effects against HER2-negative
cells. Third, an olive oil-rich diet negatively influences
experimental mammary tumorigenesis in rats likewise decreasing
HER2 expression levels. If early 1600s Castelvetro's salads can be
used as dietary protocols capable to protecting women against
biologically aggressive HER2-positive breast cancer subtypes is an
intriguing prospect that warrants to be evaluated in human pilot
studies in the future. Here, at least, we would like to recognise
Giacomo Castelvetro as the father of modern nutritional genomics
in oncology. [Colomer, Ramon] MD Anderson Int Madrid, Madrid

J Barchitta, M; Maugeri, A; Quattrocchi, A; Agrifoglio, O; Scalisi, A; Agodi, A Barchitta, Martina; Maugeri, Andrea; Quattrocchi, Annalisa; Agrifoglio, Ottavia; Scalisi, Aurora; Agodi, Antonella The Association of Dietary Patterns with High-Risk Human Papillomavirus Infection and Cervical Cancer: A Cross-Sectional Study in Italy NUTRIENTS English Article

cervical intraepithelial neoplasia; Mediterranean diet score; principal component analysis; Western diet; prudent diet NATURAL-HISTORY; VITAMIN-A; PREVENTION; FOLATE; WOMEN; EPIDEMIOLOGY; EPIGENOME; NEOPLASIA Specific foods and nutrients help prevent the progression of persistent high-risk human papillomavirus (hrHPV) infection to cervical cancer (CC). The aim of this study was to investigate dietary patterns which may be associated with hrHPV status and the risk of high-grade cervical intraepithelial neoplasia (CIN2+). Overall, 539 eligible women, including 127 with CIN2+, were enrolled in a cross-sectional study, and tested for hrHPV infection. Food intake was estimated using a food frequency questionnaire. Logistic regression models were applied. Using the Mediterranean Diet Score, we demonstrated that, among 252 women with a normal cervical epithelium, medium adherence to the Mediterranean diet decreased the odds of hrHPV infection when compared to low adherence (adjOR = 0.40, 95%CI = 0.22-0.73). Using the principal component analysis, we also identified two dietary patterns which explained 14.31% of the variance in food groups intake. Women in the third and fourth quartiles of the "Western pattern" had higher odds of hrHPV infection when compared with first quartile (adjOR = 1.77, 95% CI = 1.04-3.54 and adjOR = 1.97, 95%CI = 1.14-4.18, respectively). Adjusting for hrHPV status and age, women in the third quartile of the "prudent pattern" had lower odds of CIN2+ when compared with those in the first quartile (OR = 0.50, 95%CI = 0.26-0.98). Our study is the first to demonstrate the association of dietary patterns with hrHPV infection and CC and discourages unhealthy habits in favour of a Mediterranean-like diet.

Plasma Alkylresorcinols,
 Biomarkers of Whole-Grain Wheat and Rye Intake, and Incidence of
 Colorectal Cancer JNCI-JOURNAL OF THE NATIONAL CANCER
 INSTITUTE English Article

DIETARY FIBER; COLON-CANCER; RISK;
 REPRODUCIBILITY; COHORT; INTERVENTION; CONSUMPTION; VEGETABLES;
 PRODUCTS; HEALTH Background Few studies have investigated the
 association between whole-grain intake and colorectal cancer.
 Because whole-grain intake estimation might be prone to
 measurement errors, more objective measures (eg, biomarkers) could

assist in investigating such associations. **Methods** The association between alkylresorcinols, biomarkers of whole-grain rye and wheat intake, and colorectal cancer incidence were investigated using prediagnostic plasma samples from colorectal cancer case patients and matched control subjects nested within the European Prospective Investigation into Cancer and Nutrition. We included 1372 incident colorectal cancer case patients and 1372 individual matched control subjects and calculated the incidence rate ratios (IRRs) for overall and anatomical subsites of colorectal cancer using conditional logistic regression adjusted for potential confounders. Regional differences (Scandinavia, the Mediterranean, Central Europe) were also explored. **Results** High plasma total alkylresorcinol concentration was associated with lower incidence of distal colon cancer; the adjusted incidence rate ratio of distal colon cancer for the highest vs lowest quartile of plasma total alkylresorcinols was 0.48 (95% confidence interval [CI] = 0.28 to 0.83). An inverse association between plasma total alkylresorcinol concentrations and colon cancer was found for Scandinavian participants (IRR per doubling = 0.83; 95% CI = 0.70 to 0.98). However, plasma total alkylresorcinol concentrations were not associated with overall colorectal cancer, proximal colon cancer, or rectal cancer. Plasma alkylresorcinols concentrations were associated with colon and distal colon cancer only in Central Europe and Scandinavia (ie, areas where alkylresorcinol levels were higher). **Conclusions** High concentrations of plasma alkylresorcinols were associated with a lower incidence of distal colon cancer but not with overall colorectal cancer, proximal colon cancer, and rectal cancer. Accidental traffickers: qualitative findings on labour
recruitment in Ethiopia GLOBALIZATION AND HEALTH
English Article Irregular
migration; Trafficking; Ethiopia; Labour recruitment; Domestic
workers; Middle east; Qualitative research MIGRATION BROKERS;

DOMESTIC WORKERS; MODERN SLAVERY; SEX WORKERS; MIGRANTS; HEALTH; ECONOMY; RISK BackgroundThe growth of labour migration and associated risks of human trafficking and exploitation remain significant global human rights and health challenges. There is increasing policy interest in addressing structural determinants of adverse migration outcomes such as migrants' use of informal employment recruiters. In Ethiopia, "safe migration" policies have introduced regulations for registered private employment agencies and penalties for anyone else placing migrants into work overseas. Yet migrants continue to use informal facilitators who are often demonised as traffickers without evidence of their motivations, experiences or perceptions. We conducted qualitative interviews with 28 informal facilitators as part of a study into how recruitment practices shape risks for female migrants seeking domestic work in the Middle East and Gulf States. We present the realities of irregular recruitment on the ground, and how these practices are affected by policies that dichotomise recruiters into legal/safe and illegal/unsafe categories. ResultsWe identified four main themes. First, arranging migration from rural areas differs from in the capital, Addis Ababa, where laws and regulations originate. Outside Addis Ababa, registration was difficult for facilitators to arrange, with little incentive to do so due to its lack of importance to prospective migrants. Second, the ability to circumvent legal requirements was considered an advantage of informal facilitators because it reduced costs and expedited migrants' departure. Third, facilitators did not work alone but operated in long "chains" of diverse actors. This meant migrants' safety was not determined by any given individual, but spread across numerous people involved in sending a migrant abroad, some of whom might be registered and others not. And finally, facilitators did not believe they could realistically safeguard migrants once they were outside of Ethiopia and working under different laws and employers. ConclusionsFindings from this study add to a growing body of work demonstrating the diversity of people involved in the migration process, and consequent oversimplification of popular policy solutions. A more effective approach might be to constructively engage informal facilitators and identify ways they could assist with referring migrant workers to registered agencies and safe employment, rather than criminalising their participation. Antiproliferative and antioxidant effects on breast cancer cells of oleuropein and its semisynthetic peracetylated derivatives

FOOD CHEMISTRY
English Article Olive
leaves; Oleuropein; Green chemistry; Breast cancer OLIVE OIL; PHENOLIC-COMPOUNDS; MEDITERRANEAN DIET; HYDROXYTYROSOL; RISK; HL60; PROLIFERATION; INHIBITION; EXTRACTS Olive leaves extracts are a natural source of polyphenols, mainly oleuropein, widely considered to be potentially beneficial for health. This study focused on evaluation of the anti-tumoural activities of some oleuropein peracetylated derivatives, obtained with "green chemical" methodologies, against two human breast cancer cell lines. MCF-7 and T-47D cells were treated with oleuropein, peracetylated oleuropein, peracetylated aglycone and peracetylated hydroxytyrosol and the effects on growth and viability were investigated. Antioxidant effects were analysed after treatment with hydrogen peroxide. The peracetylated compounds exerted higher antiproliferative effects than oleuropein, by an arrest of cell cycle progression, associated with a strong antioxidant activity. Our results demonstrate that olive leaves, a by-product of olive manufacture, may provide a precious source of chemical derivatives, obtainable by peracetylation of oleuropein derivatives, which provide beneficial properties for human health. Diet Quality and Breast Cancer Incidence in the
Multiethnic Cohort EUROPEAN JOURNAL OF CLINICAL NUTRITION
English Article

PATTERNS; INDEXES; OBESITY; RISK This study investigated the relation of diet quality indexes (DQI) with breast cancer incidence among women from the Multiethnic Cohort (MEC). Participants completed a questionnaire with a validated food frequency questionnaire. Scores for Healthy Eating Index 2015 (HEI-2015), Alternate Healthy Eating Index 2010 (AHEI-2010), alternate Mediterranean diet score (aMED), and Dietary Approaches to Stop Hypertension (DASH) were divided into quintiles (Q1-Q5). Cox regression was applied to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for DQIs and breast cancer risk adjusted for known risk factors. The respective HRs for Q5 vs. Q1 were: 1.06 (95% CI, 0.98-1.14) for HEI-2015, 0.96 (95% CI, 0.90-1.04) for AHEI-2010, 1.01 (95% CI, 0.94-1.09) for aMED, and 0.95 (95% CI, 0.88-1.02) for DASH (p(trend) > 0.05 for all). However, overweight and obesity were significantly associated with breast cancer incidence. Despite the null association for DQIs, diet quality may lower breast cancer risk through its positive influence on weight status.  care, MovIS: study protocol for a randomized clinical trial on
 nutrition and exercise educational programs for breast cancer
 survivors TRIALS English Article

Breast cancer; Physical activity; Exercise;
 Mediterranean diet; Quality of life; Health-related parameters;
 Prevention QUALITY-OF-LIFE; LONG-TERM; GUIDELINES Background
 Breast cancer (BC) is the most common invasive cancer in women,
 and exercise can significantly improve the outcomes of BC
 survivors. MovIS (Movement and Health Beyond Care) is a randomized
 controlled trial aimed to evaluate the potential health benefits
 of exercise and proper nutritional habits. This study aims to
 assess the efficacy of aerobic exercise training in improving
 quality of life (QoL) and health-related factors in high-risk BC.
 Methods One hundred seventy-two BC survivor women, aged 30-70
 years, non-metastatic, stage 0-III, non-physically active, 6-12
 months post-surgery, and post chemo- or radiotherapy, will be
 recruited in this study. Women will be randomly allocated to the
 intervention arm (lifestyle recommendations and MovIS Training) or
 control arm (lifestyle recommendations). The MovIS training
 consists of 12 weeks of aerobic exercise training (2 days/week of
 supervised and 1 day/week of unsupervised exercise) with a
 progressive increase in exercise intensity (40-70% of heart rate
 reserve) and duration (20-60 min). Both arms will receive
 counseling on healthy lifestyle habits (nutrition and exercise)
 based on the World Cancer Research Fund International (WCRF) 2018
 guidelines. The primary outcome is the improvement of the QoL. The
 secondary outcomes are improvement of health-related parameters
 such as Mediterranean diet adherence, physical activity level,
 flexibility, muscular fitness, fatigue, cardiorespiratory fitness
 (estimated maximal oxygen uptake), echocardiographic parameters,
 heart rate variability (average of the standard deviations of all
 5 min normal to normal intervals (ASDNN/5 min) and 24 h very low
 and low frequency), and metabolic, endocrine, and inflammatory
 serum biomarkers (glycemia, insulin resistance, progesterone,
 testosterone, and high-sensitivity C-reactive protein). Discussion
 This trial aims to evaluate if supervised exercise may improve QoL

and health-related factors of BC survivors with a high risk of recurrence. Findings from this project could provide knowledge improvement in the field of exercise oncology through the participation of a multidisciplinary team that will provide a coordinated program of cancer care to improve healthcare quality, improve prognosis, increase survival times and QoL, and reduce the risk of BC recurrence. Post Diagnosis Diet Quality and Colorectal Cancer Survival in Women PLOS ONE English Article SYSTEMIC INFLAMMATORY

RESPONSE; CORONARY-HEART-DISEASE; C-REACTIVE PROTEIN; MEDITERRANEAN DIET; PROSPECTIVE COHORT; COLON-CANCER; ALL-CAUSE; RISK; MORTALITY; PATTERNS Background: Dietary factors are known to influence colorectal cancer (CRC) risk, however, their association with CRC survival is unclear. Therefore, we prospectively examined the association between diet quality scores, dietary patterns and colorectal cancer (CRC) survival. Methods: 1201 women diagnosed with stage I-III CRC between 1986 and 2008, were followed through 2010. Diet was assessed via a food frequency questionnaire administered at least 6 months after diagnosis. We computed the Alternate Healthy Eating Index-2010 (AHEI-2010), alternate Mediterranean Diet score (aMED) and Dietary Approaches to Stop Hypertension score (DASH) and derived two dietary patterns, Western (unhealthy) and prudent (healthy), by principal component analysis for each woman. Results: During follow-up, we documented 435 deaths, including 162 from CRC. After adjusting for potential confounders, only a higher AHEI-2010 score was significantly associated with lower overall mortality (HR comparing extreme quintiles=0.71, 95% CI 0.52-0.98, p trend=0.01) as well as borderline significantly with lower risk of CRC mortality by the trend test (HR Q5 vs Q1=0.72, 95% CI=0.43-1.21, p trend=0.07). When AHEI-2010 components were examined separately, inverse associations for overall mortality were primarily accounted for by moderate alcohol intake (HR comparing abstainers vs 5-15 g/d=1.30, 95% CI=1.05-1.61) and lower intake of sugar sweetened beverages and fruit juices combined (HR for each additional serving=1.11, 95% CI=1.01-1.23). No other diet quality score or dietary pattern was associated with overall or CRC-specific mortality. Conclusion: Higher AHEI-2010 score may be associated with lower overall mortality, moderate alcohol consumption and lower consumption of sugar sweetened beverages and juices combined appeared to account for most of the observed associations. Ganoderma lucidum; melanoma; breast cancer; inflammation; cytokines; curcumin; cell viability IN-VITRO; CELLS; INTERLEUKIN-6; TRITERPENOIDES; POLYSACCHARIDES; METASTASIS; INHIBITION; MECHANISMS; SURVIVAL; VIVO Among the most important traditional medicinal fungi, Ganoderma lucidum has been used as a therapeutic agent for the treatment of numerous diseases, including cancer, in Oriental countries. The aim of this study is to investigate the anti-inflammatory, anticancer and anti-metastatic activities of Ganoderma lucidum extracts in melanoma and triple-negative breast cancer cells. Ganoderma lucidum extracts were prepared by using common organic solvents; MDA-MB 231 and B16-F10 cell lines were adopted as cellular models for triple-negative breast cancer and melanoma and characterized for cell viability, wound-healing assay and measurement of cytokines secreted by cancer cells under pro-inflammatory conditions (incubation with lipopolysaccharide, LPS) and pretreatment with Ganoderma lucidum extract at different concentrations. Our study demonstrates, for the first time, how Ganoderma lucidum extracts can significantly inhibit the release of IL-8, IL-6, MMP-2 and MMP-9 in cancer cells under pro-inflammatory condition. Interestingly, Ganoderma lucidum extracts significantly also decrease the viability of both cancer cells in a time- and concentration-dependent manner, with abilities to reduce cell

migration over time, which is correlated with a lower release of matrix metalloproteases. Taken together, these results indicate the possible use of Ganoderma lucidum extract for the therapeutic management of melanoma and human triple-negative breast cancer.

Frailty in older-age European migrants: Cross-sectional and longitudinal analyses of the Survey of Health, Aging and Retirement in Europe (SHARE) SOCIAL SCIENCE & MEDICINE

English Article

Migration; Frailty; Trajectories; Healthcare policy; Acculturation COUNTRIES; DETERMINANTS; IMMIGRATION; MIGRATION; MORTALITY; POLICIES; PEOPLE Frailty correlates with morbidity and is superior to chronological age in predicting mortality. Frailty of older migrants has important implications for the demands placed on healthcare systems. Examining 95,635 Europeans in the Survey of Health, Aging and Retirement in Europe, we investigated cross-sectional and longitudinal associations between migration

and frailty at ages > 50 years. We examined whether associations differed by countries' level of healthcare coverage and access for migrants and tested mediation by home-ownership and citizenship. Cross-sectionally, first-generation migrants > 50 years old were, on average, 16.4% (95% confidence interval [CI]: 14.6, 18.2%) frailer than non-migrants after confounder-adjustment. This decreased to 12.1% (95% CI: 10.1, 14.1%) after adjustment for citizenship. The strength of association between migrant status and frailty was greater in migrants from low-or-middle-income countries, compared with migrants from high-income countries. Migrants into Northern, Western and Eastern Europe were 37.3% (95% CI: 33.2, 41.5%), 12.2% (95% CI: 10.0, 14.6%) and 5.0% (95% CI: 0.5, 9.6%) frailer than non-migrants, respectively, but migrants into Southern Europe were no frailer than non-migrants. The strength of association between migrant status and frailty was greater in countries with lower healthcare coverage and access for migrants. However, citizenship attenuated this difference. Longitudinally, migrants were frailer than non-migrants at 50 years old and trajectories converged over time until migrants and non-migrants were equally frail by 80-90 years. Our work finds no evidence of the 'healthy migrant effect' outside of Southern Europe in older migrants and suggests that acculturation is a key determinant of migrant health. [Walkden, G. Lifestyle Intervention Program on Cardiometabolic Health in Breast
Cancer Survivors during the COVID-19 Lockdown JOURNAL OF
CLINICAL MEDICINE English Article

COVID-19; breast cancer survivors; home-based lifestyle intervention; Mediterranean diet; exercise; cardiotoxicity; cardiovascular fitness; heart rate variability; secondary and tertiary prevention HEART-RATE-VARIABILITY; PHYSICAL-ACTIVITY QUESTIONNAIRE; C-REACTIVE PROTEIN; QUALITY-OF-LIFE; METABOLIC SYNDROME; ADJUVANT CHEMOTHERAPY; CARDIOVASCULAR RESERVE; EXERCISE GUIDELINES; MEDITERRANEAN DIET; INSULIN-RESISTANCE This study aimed to evaluate the cardiometabolic effects of a home-based lifestyle intervention (LI) in breast cancer survivors (BCSs) during the COVID-19 lockdown. In total, 30 BCSs (women; stages 0-II; non-metastatic; aged 53.5 $\pm$ 7.6 years; non-physically active; normal left ventricular systolic function) with a risk factor for recurrence underwent a 3-month LI based on nutrition and exercise. Anthropometrics, Mediterranean diet adherence, physical activity level (PAL), cardiorespiratory fitness (VO₂max), echocardiographic parameters, heart rate variability (average standard deviation of NN intervals (ASDNN/5 min) and 24 h very- (24 hVLF) and low-frequency (24 hLF)), and metabolic, endocrine, and inflammatory serum biomarkers (glycemia, insulin resistance, progesterone, testosterone, and high-sensitivity C-reactive protein (hs-CRP)) were evaluated before (T₀) and after (T₁) the LI. After the LI, there were improvements in: body mass index (kg/m²): T₀ = 26.0 $\pm$ 5.0, T₁ = 25.5 $\pm$ 4.7; p = 0.035); diet (Mediet score: T₀ = 6.9 $\pm$ 2.3, T₁ = 8.8 $\pm$ 2.2; p < 0.001); PAL (MET-min/week: T₀ = 647 $\pm$ 547, T₁ = 1043 $\pm$ 564; p < 0.001); VO₂max (mL center dot min(-1)center dot kg(-1): T₀ = 30.5 $\pm$ 5.8, T₁ = 33.4 $\pm$ 6.8; p < 0.001); signs of diastolic dysfunction (participants: T₀ = 15, T₁ = 10; p = 0.007); AS-DNN/5 min (ms: T₀ = 50.6 $\pm$ 14.4, T₁ = 55.3 $\pm$ 16.7; p = 0.032); 24 hLF (ms(2): T₀ = 589 $\pm$ 391, T₁ = 732 $\pm$ 542; p = 0.014); glycemia (mg/dL: T₀ = 100.8 $\pm$ 11.4, T₁ = 91.7 $\pm$ 11.0; p < 0.001); insulin resistance (HOMA-IR score: T₀ = 2.07 $\pm$ 1.54, T₁ = 1.53 $\pm$ 1.11; p = 0.005); testosterone (ng/mL: T₀ = 0.34 $\pm$ 0.27, T₁ = 0.24 $\pm$ 0.20; p = 0.003); hs-CRP (mg/L: T₀ = 2.18 $\pm$ 2.14, T₁ = 1.75 $\pm$ 1.74; p = 0.027). The other parameters did not change. Despite the home-confinement, LI based on exercise and nutrition improved cardiometabolic health in BCSs. Knowledge by physicians concerning cervical cancer and
testing: Benimellal province, Morocco EASTERN MEDITERRANEAN
HEALTH JOURNAL French Article

GENERAL-PRACTITIONERS; PRIMARY-CARE;
ATTITUDES; PREVENTION; DIAGNOSIS; REGION; IMPACT; SMEAR

Background: Cervical cancer is the second most common cancer
among women after skin cancer. Aims: This study aimed to evaluate
the knowledge of general practitioners with regard to cervical

cancer in the province of Benimellal, Morocco. Methods: A cross-sectional study using a self-reported questionnaire given to 71 general practitioners operating in public and private healthcare centres in the province of Benimellal. Results: Almost half of general practitioners (49.3%) were not aware of a national plan for the prevention and control of cancer in Morocco, and only 18.2% gave a correct response on the incidence rate for cervical cancer. The human papilloma virus as the principle risk factor was identified by 21% of general practitioners. Conclusions: The knowledge of general practitioners was deficient and therefore initial and continuing training on cervical cancer is required.

J KEYDAR, I; SELZER, G; CHAITCHIK, S; HAREUVENI, M; KARBY, S; HIZI, A KEYDAR, I; SELZER, G; CHAITCHIK, S; HAREUVENI, M; KARBY, S; HIZI, A A VIRAL-ANTIGEN AS A MARKER FOR THE PROGNOSIS OF HUMAN-BREAST CANCER EUROPEAN JOURNAL OF CANCER & CLINICAL ONCOLOGY English Article An

antigen present in human breast tumor cells, and which is immunologically related to the envelope protein (gp52) of murine mammary tumor virus, was used as a marker for the detection of breast cancer in an Israeli population. The antigen was detectable in 128 of 204 breast carcinoma tested (62.7%). The immunological reaction was not detected in normal breast tissue, benign breast tumors, ductal hyperplasia or in primary malignancies in other organs. A significantly higher percentage of cases with demonstrable antigen was found in Israeli women born in North Africa (78%) compared to women of European origin (60.6%). The frequency of detection of the antigen was higher in stage IV (80%) compared to state I (15%), suggesting that the gp52 cross-reacting antigen is a marker for the severity of the disease. A retrospective study of 97 cases of stage II breast cancer shows that if the antigen is detected at the time of mastectomy, an unfavorable prognosis can usually be predicted. Survival data analysis indicates that patients without detectable antigen survived significantly longer than those with a detectable antigen. CENTONZE, S; BOEING, H; LEOCI, C; GUERRA,
V; MISCIAGNA, G DIETARY HABITS AND COLORECTAL-CANCER
IN A LOW-RISK AREA - RESULTS FROM A POPULATION-BASED CASE-CONTROL
STUDY IN SOUTHERN ITALY NUTRITION AND CANCER-AN INTERNATIONAL
JOURNAL English Article

COLON Many epidemiological studies have focused
on the relationships between diet and colorectal cancer, but only
a few have been conducted in the Mediterranean area. A population-
based case-control study was carried out from July 1987 to June
1989 in a low-risk area in Southern Italy. By means of an 'ad
hoc' tumor registry, 132 diagnosed colorectal cancers were
detected during the two years of study. One hundred nineteen of
these 132 colorectal cancer cases were interviewed about their
personal dietary habits with use of a questionnaire concerning the
frequency of consumption of 70 foods or beverages. An equal number
of controls was randomly selected from the lists of general
practitioners of the area during the same period and interviewed
with the same food frequency questionnaire. In a multivariate
analysis, the relative risks (RRs) of developing colorectal cancer
were estimated according to the different levels of consumption of
food groups and selected food items. All RRs were adjusted for
age, sex, education, smoking status, and modifications in diet in
the previous 10 years. The risk of colorectal cancer increased
nearly threefold for the highest level of consumption of foods
with a high content of refined sugar [RR = 2.75, 95% confidence
interval (CI) 1.26-5.97] and for the consumption of wine (>1
l/day) (RR = 3.22, 95% CI 1.05-9.88). An inverse relationship was
revealed for the highest consumption of raw and cooked vegetables
(RR = 0.51, 95% CI 0.25-1.04) and dairy products (RR = 0.46, 95%
CI 0.22-0.98) and for the consumption of more than two cups of
coffee per day (RR = 0.38, 95% CI 0.16-0.89). In this
Mediterranean area, the main source of calories, cereals, did not
show a significant relationship with colorectal cancer. These
findings support the hypothesis that the local Mediterranean
dietary pattern could explain the low risk of colorectal cancer.

Assessment of Diet Quality and Risk of Precursors of Early-Onset
Colorectal Cancer JNCI-JOURNAL OF THE NATIONAL CANCER
INSTITUTE English Article

PATTERNS; METABOLITES; ADENOMA Background: The
role of poor diet quality in the rising incidence of colorectal
cancer (CRC) diagnosed younger than age 50 years has not been
explored. Based on molecular features of early-onset CRC, early-
onset adenomas are emerging surrogate endpoints. Methods: In a
prospective cohort study (Nurses' Health Study II), we evaluated 2
empirical dietary patterns (Western and prudent) and 3
recommendation-based indexes (Dietary Approaches to Stop
Hypertension [DASH], Alternative Mediterranean Diet [AMED], and
Alternative Healthy Eating Index [AHEI]-2010) with risk of early-
onset adenoma overall and by malignant potential (high-risk: ≥ 1
cm, tubulovillous or villous histology, high-grade dysplasia, or
 ≥ 3 adenomas), among 29 474 women with 1 or more lower endoscopy
before age 50 years (1991-2011). Multivariable logistic
regressions were used to estimate odds ratios (ORs) and 95%
confidence intervals (CIs). Results: We documented 1157 early-
onset adenomas with 375 at high risk. Western diet was positively
associated, whereas prudent diet, DASH, AMED, and AHEI-2010 were
inversely associated with risk of early-onset adenoma. The
associations were largely confined to high-risk adenomas (the
highest vs lowest quintile: Western, OR = 1.67, 95% CI = 1.18 to
2.37; prudent, OR = 0.69, 95% CI = 0.48 to 0.98; DASH, OR = 0.65,
95% CI = 0.45 to 0.93; AMED, OR = 0.55, 95% CI = 0.38 to 0.79;
AHEI-2010, OR = 0.71, 95% CI = 0.51 to 1.01; all P-trend $\leq .03$),
driven by those identified in the distal colon and rectum (all P-
trend $\leq .04$, except AMED: P-trend = .14). Conclusion: Poor diet
quality was associated with an increased risk of early-onset
distal and rectal adenomas of high malignant potential. These
findings provide preliminary but strong support to the role of
diet in early-onset CRC. [Zheng, Xiaobin; Liu, Jie; Cao, Yin]

Geographic and age variations in mutational processes in colorectal cancer NATURE English Article; Early Access GENOMIC LANDSCAPE; READ ALIGNMENT; SIGNATURES; EPIDEMIOLOGY; BIOLOGY

Incidence rates of colorectal cancer vary geographically and have changed over time¹. Notably, in the past two decades, the incidence of early-onset colorectal cancer, which affects individuals below 50 years of age, has doubled in many countries^{2, 3, 4-5}. The reasons for this increase are unknown. Here we investigate whether mutational processes contribute to geographic and age-related differences by examining 981 colorectal cancer genomes from 11 countries. No major differences were found in microsatellite-unstable cancers, but variations in mutation burden and signatures were observed in the 802 microsatellite-stable cases. Multiple signatures, most with unknown aetiologies, exhibited varying prevalence in Argentina, Brazil, Colombia, Russia and Thailand, indicating geographically diverse levels of mutagenic exposure. Signatures SBS88 and ID18, caused by the bacteria-produced mutagen colibactin^{6,7}, had higher mutation loads in countries with higher colorectal cancer incidence rates. SBS88 and ID18 were also enriched in early-onset colorectal cancers, being 3.3 times more common in individuals who were diagnosed before 40 years of age than in those over 70 years of age, and were imprinted early during colorectal cancer development. Colibactin exposure was further linked to APC driver mutations, with ID18 being responsible for about 25% of APC driver indels in colibactin-positive cases. This study reveals geographic and age-related variations in colorectal cancer mutational processes, and suggests that mutagenic exposure to colibactin-producing bacteria in early life may contribute to the increasing incidence of early-onset colorectal cancer.  Label-free enrichment of MCF7 breast cancer cells from
 leukocytes using continuous flow dielectrophoresis ELECTROPHORESIS
 English Article

Circulating tumor cells (CTCs) present in the bloodstream are strongly linked to the invasive behavior of cancer; therefore, their detection holds great significance for monitoring disease progression. Currently available CTC isolation tools are often based on tumor-specific antigen or cell size approaches. However, these techniques are limited due to the lack of a unique and universal marker for CTCs, and the overlapping size between CTCs and regular blood cells. Dielectrophoresis (DEP), governed by the intrinsic dielectric properties of the particles, is a promising marker-free, accurate, fast, and low-cost technique that enables the isolation of CTCs from blood cells. This study presents a continuous flow, antibody-free DEP-based microfluidic device to

concentrate MCF7 breast cancer cells, a well-established CTC model, in the presence of leukocytes extracted from human blood samples. The enrichment strategy was determined according to the DEP responses of the corresponding cells, obtained in our previously reported DEP spectrum study. It was based on the positive-DEP integrated with hydrodynamic focusing under continuous flow. In the proposed device, the parylene microchannel with two inlets and outlets was built on top of rectangular and equally spaced isolated planar electrodes rotated certain degree relative to the main flow (13 degrees). The recovery of MCF7 cells mixed with leukocytes was 74%-98% at a frequency of 1 MHz and a magnitude of 10-12 V-pp. Overall, the results revealed that the presented system successfully concentrates MCF7 cancer cells from leukocytes, ultimately verifying our DEP spectrum study, in which the enrichment frequency and separation strategy of the microfluidic system were determined. Consumption of Mediterranean versus Western Diet Leads to Distinct Mammary Gland Microbiome Populations CELL REPORTS English Article BREAST-CANCER RISK; CARDIOVASCULAR RISK; INFECTIOUS MASTITIS; ACID METABOLISM; BILE-ACIDS; ESTRADIOL; MILK; PROGESTERONE; PATTERNS; MODULATE Recent identification of a mammary gland-specific microbiome led to studies investigating bacteria populations in breast cancer. Malignant breast tumors have lower Lactobacillus abundance compared with benign lesions, implicating Lactobacillus as a

negative regulator of breast cancer. Diet is a main determinant of gut microbial diversity. Whether diet affects breast microbiome populations is unknown. In a non-human primate model, we found that consumption of a Western or Mediterranean diet modulated mammary gland microbiota and metabolite profiles. Mediterranean diet consumption led to increased mammary gland *Lactobacillus* abundance compared with Western diet-fed monkeys. Moreover, mammary glands from Mediterranean diet-fed monkeys had higher levels of bile acid metabolites and increased bacterial-processed bioactive compounds. These data suggest that diet directly influences microbiome populations outside the intestinal tract in distal sites such as the mammary gland. Our study demonstrates that diet affects the mammary gland microbiome, establishing an alternative mechanistic pathway for breast cancer prevention.

Dietary patterns and breast cancer risk in the California Teachers Study cohort AMERICAN JOURNAL OF CLINICAL NUTRITION English Article

HORMONE-THERAPY USE; ALCOHOL-CONSUMPTION; MEDITERRANEAN DIET; WOMEN Background: Evidence that diet is associated with breast cancer risk is inconsistent. Most studies have examined risks associated with specific foods and nutrients, rather than measures of overall diet. Objective: This study aimed to evaluate dietary patterns and their relation to breast cancer risk in a large cohort of women. Design: Data from 91,779 women in the California Teachers Study cohort were analyzed, including data from 4140 women with a diagnosis of invasive breast cancer made between 1995 and 2009. Five predominant dietary patterns were identified by using principal components factor analysis: a plant-based diet, high in fruit and vegetables; a high-protein, high-fat diet, high in meats, eggs, fried foods, and high-fat condiments; a high-carbohydrate diet, high in convenience foods, pasta, and bread products; an ethnic diet, high in legumes, soy-based foods, rice, and dark-green leafy vegetables; and a salad and wine diet, high in lettuce, fish, wine, low-fat salad dressing, and coffee and tea. Results: The plant-based pattern was associated with a reduction in breast cancer risk (RR: 0.85; 95% CI: 0.76, 0.95 for the highest compared with the lowest consumption quintile; P-trend = 0.003); risk reduction was greater for estrogen receptor negative progesterone receptor negative (ER PR) tumors (RR: 0.66; 95% CI: 0.48, 0.91; P-trend = 0.03). The salad and wine pattern was associated with an increased risk of estrogen receptor positive progesterone receptor positive tumors (RR: 1.29; 95% CI: 1.12, 1.49); this effect was only slightly attenuated after adjustment for alcohol consumption. Conclusion: The finding that greater consumption of a plant-based dietary pattern is associated with a reduced breast cancer risk, particularly for ER PR tumors, offers a potential avenue for prevention. Capparis zeylanica L. root extract promotes apoptosis and cell cycle arrest, inhibits epithelial-to-mesenchymal transition and triggers E-cadherin expression in breast cancer cell lines

3 BIOTECH English Article

Apoptosis; Breast cancer; Capparis zeylanica; Cell cycle; Cytotoxicity; EMT markers TOCOPHEROL COMPOSITION; SPINOSA; ANTIOXIDANT; SNAIL Capparis zeylanica L. is a climbing shrub distributed in Indian subcontinent and Mediterranean region. Almost all parts of the plant are used in folk medicine and traditional practices to treat several human ailments. The present study was aimed to investigate the role of C. zeylanica L. root extract in preventing cancerous cells growth and proliferation, as well as promoting apoptosis and cell cycle arrest in MDA-MB-231 and MCF-7 breast cancer cells. Methanolic extract of C. zeylanica L. (MECz) was prepared and characterized by LC-ESI-MS/MS analysis. In vitro cytotoxicity and anti-proliferative activity of MECz was evaluated by MTT assay, while cell viability, apoptosis and cell cycle progression by Muse Cell analyzer. Furthermore, the mRNA and protein expressions of EMT markers were assessed using qRT-PCR and

western blotting techniques, respectively. The MECz was found to be rich in phenolic compounds including chlorogenic acid, 6-gingerol, and certain triterpenes like ursolic acid etc. The apparent anti-metastasis activity of MECz was evident from IC50 value of 19.12 and 24.22 μ g/mL, respectively, on MDA-MB-231 and MCF-7 cells in MTT assay. An absolute decrease in cell viability (78.1-53.4% and 89.9-49.0%), augmented apoptosis (90.98-48.25% and 88.25-47.70%) and S phase, G(2)/M phase cell cycle arrest was found by MECz treatment on MDA-MB-231 and MCF-7 cells. The gene expression studies revealed that MECz could significantly ($p < 0.001$) regulate the expression of EMT markers such as snail, slug, zeb-1, twist-1, fibronectin, vimentin and E-cadherin at molecular level. These findings demonstrate that *C. zeylanica* L. root extract inhibits breast cancer cells growth and proliferation through regulating the expression of key EMT marker genes and proteins. Thus, MECz may be suggested as a potential anti-metastasis agent in the treatment of breast cancer.

adherence to the Mediterranean diet: An Italian experience

NUTRITION METABOLISM AND CARDIOVASCULAR DISEASES

English Article

Mediterranean diet; Validation study; Questionnaire FOOD PATTERN; DISEASE; RISK; REPRODUCIBILITY; PREVENTION; VALIDITY; INDEXES; QUALITY; OBESITY; HABITS Background and aims: A greater adherence to the Mediterranean diet has been associated with a reduced risk of major chronic diseases and cancer. The aim of the study was to assess the validity of a new short self-administered

15-item questionnaire (QueMD) to measure adherence to the Mediterranean diet in Italy. Methods and results: Four-hundred and eighty three participants to cancer-screening programmes at the European Institute of Oncology, Milan (Italy) were invited to join this study. Those interested compiled the QueMD and a validated Food Frequency Questionnaire (FFQ) reporting their usual food consumption during the previous six months. We derived the alternate Mediterranean score (aMED) from both questionnaires with values ranging from 0 (minimal adherence) to 9 (maximal adherence). Complete dietary data were available for 343 individuals (participation rates 71.0%). Spearman correlation coefficient between the responses to the 15 questions of the QueMD and corresponding food intake derived from the FFQ ranged from 0.15 to 0.84. A moderate correlation was found between the aMED scores calculated from the QueMD and the FFQ (intraclass correlation coefficient 0.50; 95% CI, 0.42-0.58), while agreement between the two instruments was only poor to fair for 7 of the 9 single items composing the aMED score, with values ranging from 53.0% for wholegrain products to 79.5% for fruits. Conclusion: This new self-administered 15-item questionnaire could be a useful tool to assess adherence to the Mediterranean diet in the Italian population. An educational intervention to improve health and nutrition literacy in hypertensive patients in Greece JOURNAL OF EDUCATION AND HEALTH PROMOTION English Article

Eating behavior; educational program; Greece; health literacy; hypertension nutrition literacyGLOBAL MEASURE; VALIDATION; BEHAVIOR BACKGROUND: Suboptimal control of blood pressure (BP) is a public health challenge in Greece. This educational intervention attempts to improve health literacy (HL) and nutrition literacy (NL) in primary healthcare (PHC) patients with hypertension (HTN). MATERIALS AND METHODS: This was a proof-of-concept (PoC) educational intervention. Twenty-four patients with HTN and low or medium levels of HL agreed to participate in this 6-week educational intervention. The program was delivered by a general practitioner (GP) in group A and by a qualified nurse in group B. Group C was the control group. The levels of HL of NL, adherence to the Mediterranean diet, and perceived stress were assessed using the European Health Literacy Survey Questionnaire 16 (HLS_EU_Q16) and part B (reading a medication label) of the High Blood Pressure-Health Literacy Scale (HBP-HLS), the Nutrition Literacy Scale-Greek (NLS-Gr), the Mediterranean Diet Adherence Screener (MEDAS), and the Perceived Stress Scale (PSS-14), respectively, together with certain socioeconomic, dietary, and lifestyle characteristics. The Kruskal-Wallis and Wilcoxon nonparametric, the Chi-square, and the McNemar-Bowker tests were used. The analysis was done with the STATA software, version 14 (MP & Associates, Sparta, Greece). RESULTS: No statistically significant differences were found in the total score of HL and NL before and after the intervention; however, the results indicate a slight improvement in HL and NL levels in the two intervention groups, together with small improvements in knowledge and behaviors related to HTN and dietary salt. A trend of improvement in the MEDAS levels in the GP's group and the HBP-HLS levels in the nurse's group was also reported. CONCLUSION: A slight improvement in HL and NL levels in the two intervention groups has been reported, and the changes, however, were not statistically significant. Integrated molecular pathway analysis informs a synergistic
combination therapy targeting PTEN/PI3K and EGFR pathways for
basal-like breast cancer BMC CANCER English

Article

Basal-like; Breast

cancer; EGFR; PTEN; Combination therapy GENE-EXPRESSION SIGNATURE;
GROWTH-FACTOR RECEPTOR; PIK3CA MUTATIONS; TUMOR-CELLS;
PHOSPHATIDYLINOSITOL 3-KINASE; TRASTUZUMAB RESISTANCE; KINASE
INHIBITORS; IN-SITU; PTEN; ACTIVATION Background: The basal-like
breast cancer (BLBC) subtype is characterized by positive staining
for basal mammary epithelial cytokeratin markers, lack of hormone
receptor and HER2 expression, and poor prognosis with currently no
approved molecularly-targeted therapies. The oncogenic signaling
pathways driving basal-like tumorigenesis are not fully
elucidated. Methods: One hundred sixteen unselected breast tumors
were subjected to integrated analysis of phosphoinositide 3-kinase
(PI3K) pathway related molecular aberrations by
immunohistochemistry, mutation analysis, and gene expression
profiling. Incidence and relationships between molecular
biomarkers were characterized. Findings for select biomarkers were
validated in an independent series. Synergistic cell killing in
vitro and in vivo tumor therapy was investigated in breast cancer
cell lines and mouse xenograft models, respectively. Results:
Sixty-four % of cases had an oncogenic alteration to PIK3CA, PTEN,
or INPP4B; when including upstream kinases HER2 and EGFR, 75 % of
cases had one or more aberration including 97 % of estrogen
receptor (ER)-negative tumors. PTEN-loss was significantly
associated to stathmin and EGFR overexpression, positivity for the
BLBC markers cytokeratin 5/14, and the BLBC molecular subtype by
gene expression profiling, informing a potential therapeutic
combination targeting these pathways in BLBC. Combination
treatment of BLBC cell lines with the EGFR-inhibitor gefitinib
plus the PI3K pathway inhibitor LY294002 was synergistic, and
correspondingly, in an in vivo BLBC xenograft mouse model,
gefitinib plus PI3K-inhibitor PWT-458 was more effective than
either monotherapy and caused tumor regression. Conclusions: Our

study emphasizes the importance of PI3K/PTEN pathway activity in ER-negative and basal-like breast cancer and supports the future clinical evaluation of combining EGFR and PI3K pathway inhibitors for the treatment of BLBC. Incorporation of Immigrants and Second Generations into the French Labour Market: Changes between Generations and the Role of Human Capital and Origins SOCIAL INCLUSION English
Article discrimination;
employment; France; human capital; immigrants; labour market;
returns to higher education; second generation; skilled workers
SEGMENTED ASSIMILATION; INEQUALITIES This article analyses the labour market incorporation of migrants and second-generation minorities in France. Using the 2013-2017 French Labour Surveys and the 2014 adhoc module, we focus on labour market outcomes-activity, employment, occupation and subjective overqualification-and measure the gaps between ethnic minorities and the majority group by origins, generation and by gender. In order to elucidate the mechanisms behind these gaps and explain ethnic disadvantages for immigrants, we take into account different factors, such as education, and factors linked to migration-duration of stay in France, language skills, foreign qualifications, nationality-with additional controls for family, socioeconomic and contextual characteristics. We also investigate the returns to higher education among second-generation minority members compared to the majority population. We show large differences by country of origins, generation and gender. Across generations, most minority members have made clear progress in terms of access to employment and skilled jobs, but ethnic penalties remain for the descendants of North-Africa, Sub-Saharan Africa and Turkey. In contrast, Asian second-generation men and women encounter slight advantages in attaining highly-skilled positions. Controlling for tertiary degrees even increases the gap with majority members mostly in access to highly-skills jobs. EUROPEAN JOURNAL OF NUTRITION English
Article Diet; Quality
indices; Breast cancer; Molecular subtypes; Mexico MEDITERRANEAN DIET; RISK; ADHERENCE; CONSUMPTION; PATTERNS; ENERGY; COHORT

BackgroundInconclusive epidemiological evidence suggests that diet quality indices may influence breast cancer (BC) risk; however, the evidence does not consider the molecular expression of this cancer.PurposeWe aimed to evaluate if diet quality is related to molecular subtypes of BC, in women residing in Northern Mexico.MethodsThis is a secondary analysis of 1,045 incident cases and 1,030 population controls from a previous case-control study, conducted between 2007 and 2011 in Northern Mexico. Information about the expression of estrogen receptor (ER), progesterone receptor (PR), and human epidermal growth factor 2 (HER2) was obtained from medical records to classify BC as luminal (ER + and/or PR+/HER2-), HER2+ (ER+/-and/or PR+/-/HER2+), or triple-negative (TN) (ER- and PR-/HER2-) cases. Food consumption was assessed with a semi-quantitative food frequency questionnaire. Diet quality was evaluated using the Mexican Diet Quality Index (MxDQI) and the Mexican Alternative Healthy Eating Index (MxAHEI). We used unconditional logistic regression models to estimate the association between Mexican diet quality indices and BC molecular subtypes.ResultsThe MxDQI was related to lower odds of BC (ORT3vsT1=0.24; 95%CI: 0.18, 0.31). Similarly, MxAHEI was negatively associated with BC (ORT3vsT1=0.43; 95%CI: 0.34, 0.54). The associations of both indices remained significant in the ER + and ER- tumors, and in the BC luminal and HER2 + molecular subtypes, except in the TN molecular subtype for MxAHEI, which was not statistically significant.ConclusionsOur findings showed that MxDQI and MxAHEI were negatively associated with BC risk regardless of its molecular subtype. Mediterranean dietary pattern and cancer risk in the EPIC cohort BRITISH JOURNAL OF CANCER English

Article Mediterranean diet; dietary patterns; cancer risk; epidemiology BREAST-CANCER; ADHERENCE; MORTALITY; SURVIVAL; POPULATION; CONFORMITY; ALCOHOL

BACKGROUND: Although several studies have investigated the association of the Mediterranean diet with overall mortality or risk of specific cancers, data on overall cancer risk are sparse. METHODS: We examined the association between adherence to Mediterranean dietary pattern and overall cancer risk using data from the European Prospective Investigation Into Cancer and

nutrition, a multi-centre prospective cohort study including 142 605 men and 335 873. Adherence to Mediterranean diet was examined using a score (range: 0-9) considering the combined intake of fruits and nuts, vegetables, legumes, cereals, lipids, fish, dairy products, meat products, and alcohol. Association with cancer incidence was assessed through Cox regression modelling, controlling for potential confounders. RESULTS: In all, 9669 incident cancers in men and 21 062 in women were identified. A lower overall cancer risk was found among individuals with greater adherence to Mediterranean diet (hazard ratio = 0.96, 95% CI 0.95-0.98) for a two-point increment of the Mediterranean diet score. The apparent inverse association was stronger for smoking-related cancers than for cancers not known to be related to tobacco (P (heterogeneity) = 0.008). In all, 4.7% of cancers among men and 2.4% in women would be avoided in this population if study subjects had a greater adherence to Mediterranean dietary pattern. CONCLUSION: Greater adherence to a Mediterranean dietary pattern could reduce overall cancer risk. Reversing the Genomic, Epigenetic, and Triple-Negative Breast Cancer-Enhancing Effects of Obesity CANCER PREVENTION RESEARCH English Article

BODY-MASS INDEX; INTERMITTENT CALORIE RESTRICTION; MAMMARY-TUMOR INCIDENCE; DIETARY-FAT REDUCTION; DISEASE RISK MARKERS; WEIGHT CHANGE; ENERGY RESTRICTION; ADIPOSE-TISSUE; DIAGNOSIS; SURVIVAL The reversibility of the procancer effects of obesity was interrogated in formerly obese C57BL/6 mice that lost weight via a nonrestricted low-fat diet (LFD) or 3 distinct calorie-restricted (CR) regimens (low-fat CR, Mediterranean-style CR, or intermittent CR). These mice, along with continuously obese mice and lean control mice, were orthotopically injected with E0771 cells, a mouse model of triple-negative breast cancer. Tumor weight, systemic cytokines, and incidence of lung metastases were elevated in the continuously obese and nonrestricted LFD mice relative to the 3 CR groups. Gene expression differed between the obese and all CR groups, but not the nonrestricted LFD group, for numerous tumoral genes associated

with epithelial-to-mesenchymal transition as well as several genes in the normal mammary tissue associated with hypoxia, reactive oxygen species production, and p53 signaling. A high degree of concordance existed between differentially expressed mammary tissue genes from obese versus all CR mice and a microarray dataset from overweight/obese women randomized to either no intervention or a CR diet. Assessment of differentially methylated regions in mouse mammary tissues revealed that obesity, relative to the 4 weight loss groups, was associated with significant DNA hypermethylation. However, the anticancer effects of the CR interventions were independent of their ability to reverse obesity-associated mammary epigenetic reprogramming. Taken together, these preclinical data showing that the procancer effects of obesity are reversible by various forms of CR diets strongly support translational exploration of restricted dietary patterns for reducing the burden of obesity-associated cancers.

Prevention Relevance: Obesity is an established risk and progression factor for triple-negative breast cancer (TNBC). Given rising global rates of obesity and TNBC, strategies to reduce the burden of obesity-driven TNBC are urgently needed. We report the genomic, epigenetic, and procancer effects of obesity are reversible by various calorie restriction regimens. Article Colorectal neoplasms;
Homeobox genes; RNA; Small interfering; Mutation INTestinal
METAPLASIA; HOMEOTIC GENES; HOX GENES; ROLES; MODEL

Background: Homeodomain transcriptional regulatory proteins, which are encoded by Homeobox (HOX) genes, play critical roles in both normal development and carcinogenesis. Previous studies have shown that the expression of HOX genes is deregulated in numerous tumors and this expression is specific to each cancer based on the arising embryonic origin tissue and the site of tumor. Method: In this in vitro study, the expression levels of HOXA10, CDX1, CDX2, TGIFLX, TGIFLY, and OCT1 genes were compared across 10 different human colorectal cancer cell lines with different differentiation stages. Subsequently, the effect of TGIFLX siRNA-mediated knockdown on the expression levels of CDX1, CDX2, and OCT1 genes was analyzed in SW948 cell line. Results: The obtained results revealed that these homeobox genes were differentially expressed in different colorectal cancer cell lines. Furthermore, the siRNA-mediated knockdown of TGIFLX led to higher levels of CDX1, CDX2, and OCT1 expression. Conclusion: Our data suggested that TGIFLX plays an important role in the upstream regulation of CDX1, CDX2, and OCT1 genes.  BREAST-CANCER AVOIDABLE - COULD DIETARY-CHANGES HELP
 INTERNATIONAL JOURNAL OF FOOD SCIENCES AND NUTRITION
 English Article
 CORONARY HEART-DISEASE; RURAL BLACK-WOMEN; SOUTH-AFRICA;
 RISK-FACTORS; FOLLOW-UP; FAT; POPULATION; ASSOCIATION; PROSPECTS;
 PATTERNS In the US, the Life time odds of developing breast
 cancer has reached one in eight, with an incidence rate of 85 per
 100 000 world population. The rate is half or less in women in
 some Mediterranean countries. At the extreme are rural African
 women whose rate is approximately 5-10 per 100 000. In African,
 compared with White women, protective factors include (1)
 reproductive behaviour, namely, slower growth before and after
 puberty, later age at menarche, high teenage pregnancy, high
 parity and long periods of lactation and amenorrhoea and (2) a
 diet of relatively low energy intake and of low-fat and high-fibre
 contents. In the Mediterranean setting, major dietary protective
 factors include a relatively low intake of saturated fat and high
 intakes of monounsaturated fat and of vegetables and fruit. Among
 White women, a reversion to protective reproductive behaviour is
 out of the question. Only in respect of diet, could significant
 avoiding action be taken. Adoption of an African type diet is
 wholly impracticable. Moreover, even conformation to a former
 Mediterranean diet, which is already changing, would be difficult,
 requiring reorientation of fat composition and large rises in
 intakes of vegetable and fruit. However, with resolution, were
 such changes made, at least by the very vulnerable, they would
 help, additionally, to protect against other diet-related cancers,
 especially colon cancer and against coronary heart disease. S

 Detection and genotyping of human papillomavirus in breast
 cancer tissues from Iraqi patients EASTERN MEDITERRANEAN
 HEALTH JOURNAL English Article
 CERVICAL-CANCER; HPV DNA; VIRUS; SEQUENCES;
 CARCINOMAS; SUBSET; WOMEN; RISK Studies have suggested a
 possible link between breast cancer pathogenesis and human
 papillomavirus (HPV) infection. This study in Iraq used in situ
 hybridization to detect the frequency and genotyping of HPV in
 tissue specimens from 129 patients diagnosed with malignant breast
 cancer, 24 with benign breast tumours and 20 healthy controls. In
 the breast cancer group, cocktail HPV genotypes were detected in
 60 (46.5%) archived tissue blocks. Of these, genotypes 16 (55.5%),

18 (58.4%), 31 (65.0%) and 33 (26.6%) were detected. Mixed HPV genotypes 16 + 18, 16 + 18 + 31, 16 + 18 + 33, 18 + 33, 16 + 31 and 18 + 31 were found in 5.0%, 25.0%, 8.3%, 7.7%, 10.0% and 13.3% of cancer cases respectively. Only 3 benign breast tumour tissues (12.5%) and none of the healthy breast tissue specimens were HPV-DNA-positive. The detection of high-oncogenic HPV genotypes in patients with breast cancer supports the hypothesis of an etiologic role for the virus in breast cancer development.

Receptor-Defined Subtypes of Breast Cancer in Indigenous Populations in Africa: A Systematic Review and Meta-Analysis PLOS MEDICINE English Article

ALDEHYDE DEHYDROGENASE 1;
MOLECULAR SUBTYPES; EGYPTIAN WOMEN; ESTROGEN-RECEPTOR; HORMONE-RECEPTOR; RISK-FACTORS; OVER-EXPRESSION; MESSENGER-RNA;
PREVALENCE; AGE Background Breast cancer is the most common female cancer in Africa. Receptor-defined subtypes are a major determinant of treatment options and disease outcomes but there is considerable uncertainty regarding the frequency of poor prognosis estrogen receptor (ER) negative subtypes in Africa. We systematically reviewed publications reporting on the frequency of breast cancer receptor-defined subtypes in indigenous populations in Africa. Methods and Findings Medline, Embase, and Global Health were searched for studies published between 1st January 1980 and 15th April 2014. Reported proportions of ER positive (ER+), progesterone receptor positive (PR+), and human epidermal growth factor receptor-2 positive (HER2+) disease were extracted and 95% CI calculated. Random effects meta-analyses were used to pool estimates. Fifty-four studies from North Africa (n=12,284 women with breast cancer) and 26 from sub-Saharan Africa (n=4,737) were eligible. There was marked between-study heterogeneity in the ER+ estimates in both regions (I²>90%), with the majority reporting proportions between 0.40 and 0.80 in North Africa and between 0.20 and 0.70 in sub-Saharan Africa. Similarly, large between-study heterogeneity was observed for PR+ and HER2+ estimates (I²>80%, in all instances). Meta-regression analyses showed that the proportion of ER+ disease was 10% (4%-17%) lower for studies based

on archived tumor blocks rather than prospectively collected specimens, and 9% (2%-17%) lower for those with 40% versus those with <40% grade 3 tumors. For prospectively collected samples, the pooled proportions for ER+ and triple negative tumors were 0.59 (0.56-0.62) and 0.21 (0.17-0.25), respectively, regardless of region. Limitations of the study include the lack of standardized procedures across the various studies; the low methodological quality of many studies in terms of the representativeness of their case series and the quality of the procedures for collection, fixation, and receptor testing; and the possibility that women with breast cancer may have contributed to more than one study. Conclusions The published data from the more appropriate prospectively measured specimens are consistent with the majority of breast cancers in Africa being ER+. As no single subtype dominates in the continent availability of receptor testing should be a priority, especially for young women with early stage disease where appropriate receptor-specific treatment modalities offer the greatest potential for reducing years of life lost. The end of the decline in cervical cancer
mortality in Spain: trends across the period 1981-2012 BMC
CANCER English Article

Uterine cervical neoplasms; Mortality rate; Spain;
Trends HUMAN-PAPILLOMAVIRUS; BURDEN; COHORT; AGE; PREVENTION;
REGRESSION Background: In Spain, cervical cancer prevention is
based on opportunistic screening, due to the disease's
traditionally low incidence and mortality rates. Changes in sexual

behaviour, tourism and migration have, however, modified the probability of exposure to human papilloma virus among Spaniards. This study thus sought to evaluate recent cervical cancer mortality trends in Spain. Methods: We used annual female population figures and individual records of deaths certified as cancer of cervix, reclassifying deaths recorded as unspecified uterine cancer to correct coding quality problems. Joinpoint models were fitted to estimate change points in trends, as well as the annual (APC) and average annual percentage change. Log-linear Poisson models were also used to study age-period-cohort effects on mortality trends and their change points. Results: 1981 marked the beginning of a decline in cervical cancer mortality (APC(1981-2003): -3.2; 95% CI:-3.4;-3.0) that ended in 2003, with rates reaching a plateau in the last decade (APC(2003-2012): 0.1; 95% CI:-0.9; 1.2). This trend, which was observable among women aged 45-46 years (APC(2003-2012): 1.4; 95% CI:-0.1; 2.9) and over 65 years (APC(2003-2012): -0.1; 95% CI:-1.9; 1.7), was clearest in Spain's Mediterranean and Southern regions. Conclusions: The positive influence of opportunistic screening is not strong enough to further reduce cervical cancer mortality rates in the country. Our results suggest that the Spanish Health Authorities should reform current prevention programmes and surveillance strategies in order to confront the challenges posed by cervical cancer.

Benchmarking epidemiological characteristics of cervical cancer in advance of change in screening practice and commencement of vaccination AUSTRALIAN AND NEW ZEALAND JOURNAL OF PUBLIC HEALTH English Article

cervix cancer; histology; time trends; screening INDIGENOUS AUSTRALIANS; HUMAN-PAPILLOMAVIRUS; QUALITY ASSURANCE; SURVIVAL; TRENDS; RATES Objectives: To investigate trends in cervical cancer incidence, mortality and survival by histology for benchmarking purposes ahead of practice change and the introduction of Human Papilloma Virus (HPV) vaccine. Methods: Using data from the South Australian Cancer Registry, age-standardised rates are presented for four-year periods from 1977 to 2004. Socio-demographic and secular predictors of glandular as opposed to squamous cancers are investigated, using multivariable logistic regression. Disease-specific survivals are analysed using Kaplan-Meier product-limit estimates and Cox proportional hazards regression. Results: Incidence and mortality rates reduced by 55.1% and 59.3% respectively between 1977-80 and 2001-04, with larger reductions for squamous than glandular cancers. The ratio of squamous to glandular cancer incidence reduced from 5.41 in 1977-88 to 2.81 in 1993-2004, with a corresponding reduction from 5.21 to 3.01 for mortality. Compared with squamous cancers, glandular lesions were more common in patients from higher socioeconomic areas, but less common in those over 70 years of

age, Aboriginal patients, and those born in Southern Europe.
 Conclusion: The proportion of cancers comprising glandular lesions
 has increased, possibly reflecting prevention of squamous cancers
 through treatment of screen-detected preinvasive lesions.
 Additional mortality reductions from screening may be limited
 where the proportion of glandular lesions is high, with
 vaccination offering the best prospects for gains in the long
 term. Priority should be given to Aboriginal and Torres Strait
 Islander women in vaccination programs in view of their high death
 rate from cervical cancer. Dept Hlth, Epidemiol Branch, Adelaide,

J Benson, OG; Siciliano, A Gonzalez
 Benson, Odessa; Siciliano, Antonio A Rights-Based
 Framework in Global Social Work Education and International
 Development Work: Insights from a Global Independent Study in
 Tunisia JOURNAL OF HUMAN RIGHTS AND SOCIAL WORK

English Article Human
 rights framework; Social work field education; Activism;
 Inequality; Capacity building; Global social work FIELD;
 GLOBALIZATION; CHALLENGES In this reflective analysis, we use a
 rights-based framework from international development studies to
 examine a global independent study (GIS) course as social work
 field education. Our GIS course entailed fieldwork with a Tunisia-
 based migrant-led organization that advocates for missing migrants
 who have gone missing en route from Tunisia to Italy via the
 Mediterranean Sea. We use our case study to illustrate the five
 elements to a human rights framework. Rights and obligations, as
 two elements, set the terms of the engagement for fieldwork.
 Capacity building moves beyond service delivery and teaches
 empowerment. Inequality and poverty focus on structural aspects:
 policies, institutions, and sociopolitical contexts related to
 fieldwork. Activism and advocacy facilitate the student's
 participation in affecting change. The prioritizing of action in
 development work is thus applicable for teaching human rights in
 social work education "in the field," which requires going from
 theory to practice. [Gonzalez Benson, Odessa] Univ Michigan,

The present study aimed to provide an update on the incidence, mortality, and burden of FBC in 2019, based on the Global Burden of Disease (GBD) Study. MaterialsThe incidence, death rate, disability-adjusted life years (DALYs), years of life lost (YLLs), years lived with disability (YLDs), the age-standardized rates (ASR) of FBC in 204 countries, and a variety of classifications, were retrieved from the Global Burden of Disease Study. Data on tobacco use, alcohol consumption, and drug use were collected. The incidence, mortality, and burden of FBC were registered and compared between regions. Associations between age-standardized incidence rates and age-standardized mortality rates of FBC with smoking, drinking, and drug use were determined. ResultsThe highest incidence of FBC was observed in countries with a high socioeconomic status such as those of the European continent. Despite the lower incidence of FBC in countries with a low socio-demographic index (SDI), mortality rates secondary to FBC are higher in these countries than in high-income countries. The highest age-standardized mortality rate has been reported in the Eastern Mediterranean Region (EMRO), followed by the African Region (AFRO). The highest age-standardized rates of DALY and YLL per 100,000 population in 2019 were observed in lower-income countries, while the highest ASR of YLD per 100,000 population was reported in high-income countries. ConclusionThe present GBD-based study provides a comprehensive review of the incidence, mortality, and burden of FBC in 2019. The incidence of FBC is higher in regions with a higher socioeconomic status, whereas mortality rates and DALYs are higher in poorly developed regions. We suggest better screening measures and early detection programs for the latter regions.

Association of Diet Quality With Survival Among People With Metastatic Colorectal Cancer in the Cancer and Leukemia B and Southwest Oncology Group 80405 Trial

JAMA NETWORK OPEN English Article
 QUESTIONNAIRE; REPRODUCIBILITY;
 REGRESSION; VALIDITY; VALIDATION; RECURRENCE; PATTERNS

Importance Diet has been associated with survival in patients with stage I to III colorectal cancer, but data on patients with metastatic colorectal cancer are limited. Objective To examine the association between diet quality and overall survival among individuals with metastatic colorectal cancer. Design, Setting, and Participants This was a prospective cohort study of patients with metastatic colorectal cancer who were enrolled in the Cancer and Leukemia Group B (Alliance) and Southwest Oncology Group 80405 trial between October 27, 2005, and February 29, 2012, and followed up through January 2018. Exposures Participants completed a validated food frequency questionnaire within 4 weeks after initiation of first-line treatment for

metastatic colorectal cancer. Diets were categorized according to the Alternative Healthy Eating Index (AHEI), Alternate Mediterranean Diet (AMED) score, Dietary Approaches to Stop Hypertension (DASH) score, and Western and prudent dietary patterns derived using principal component analysis. Participants were categorized into sex-specific quintiles. Main Outcomes and Measures Multivariable hazard ratios (HRs) and 95% CIs for overall survival. Results In this cohort study of 1284 individuals with metastatic colorectal cancer, the median age was 59 (interquartile range [IQR]: 51-68) years, median body mass index was 27.2 (IQR, 24.1-31.4), 521 (41%) were female, and 1102 (86%) were White. There were 1100 deaths during a median follow-up of 73 months (IQR, 64-87 months). We observed an inverse association between the AMED score and risk of death (HR quintile 5 vs quintile 1, 0.83; 95% CI, 0.67-1.04; $P = .04$ for trend), but the point estimates were not statistically significant. None of the other diet scores or patterns were associated with overall survival. Conclusions and Relevance In this prospective analysis of patients with metastatic colorectal cancer, diet quality assessed at initiation of first-line treatment for metastatic disease was not associated with overall survival. This cohort study of patients with metastatic colorectal cancer examines associations between diet at initiation of first-line treatment and overall survival. Question Is diet quality at initiation of first-line treatment for metastatic colorectal cancer associated with overall survival? Findings In this cohort study including 1284 people with metastatic colorectal cancer enrolled between 2005 and 2012, diet quality (assessed by the Alternative Healthy Eating Index, Alternate Mediterranean Diet score, Dietary Approaches to Stop Hypertension diet score, a Western dietary pattern, and a prudent dietary pattern) was not associated with overall survival after a median follow-up of 73 months. Meaning The results of this study suggest that overall diet quality assessed at initiation of first-line treatment for metastatic colorectal cancer was not associated with overall survival. J Parma, DAL; Reynolds, GL; Muñoz, E; Ramirez, AG
Parma, Dorothy A. Long; Reynolds, Grace L.; Munoz, Edgar; Ramirez, Amelie G. Effect of an anti-inflammatory dietary intervention on quality of life among breast cancer survivors SUPPORTIVE CARE IN CANCER English Article Health-related quality of life; Mediterranean diet; Perceived Stress Scale FUNCTIONAL ASSESSMENT; STRESS; TRIAL; COMORBIDITIES; DEPRESSION; MANAGEMENT; PROGRAM; HEALTH; SCALE; CARE Purpose Behavioral interventions have been used with breast cancer survivors (BCS) in cancer pain management and post-treatment quality of life (QOL) studies. We studied the effects of an anti-inflammatory dietary intervention on QOL in BCS. Methods One hundred fifty-three overweight and obese (body mass index [BMI] $\geq$ 25 kg/m²), early stage (0-III), English-speaking BCS who had completed all cancer treatment 2 or more months prior to

enrollment were recruited into a two-arm randomized controlled trial with a 2 (group) by 3 (time) repeated measures design. Intervention components included six monthly food-preparation workshops and twelve motivational interviewing telephone calls. Endpoints included the Perceived Stress Scale (PSS), the Functional Assessment of Cancer Therapy-General (FACT-G) and Breast Cancer (FACT-B), and the Center for Epidemiologic Studies Depression Scale (CES-D). Repeated measures analysis using PROC MIXED in SAS version 9.4 was used. Results On repeated measures analysis (intent to treat), there were no differences between groups on any of the QOL outcomes except the PSS total scores. These were significantly different in the intervention group (IG; n = 76) compared to control group (CG; n = 77), showing a main effect of assignment but no effect of time and no interaction effects. Conclusion There was an impact on QOL as measured by the PSS between groups. The intervention reduced perceived stress at 6-month follow-up, but the effects dissipated by 12 months. Sources and stress and stress reduction should be a focus of future studies. Future research should also identify appropriate QOL measures that are sensitive to changes brought about by behavioral interventions. [Parma, Dorothy A. A protein microarray-based serum proteomic
investigation reveals distinct autoantibody signature in
colorectal cancer PROTEOMICS CLINICAL APPLICATIONS

English Article

autoantibody; biological pathway analysis; colorectal
cancer; parallel reaction monitoring; protein microarray; protein-
protein interaction network; proteomics; targeted proteomics

HUMAN COLON; TUMOR; MIGRATION; CHANNEL; BREAST

PurposeColorectal cancer (CRC) has been reported as the
second leading cause of cancer death worldwide. The 5-year annual
survival is around 50%, mainly due to late diagnosis, striking
necessity for early detection. This study aims to identify
autoantibody in patients' sera for early screening of cancer.
Experimental DesignThe study used a high-density human proteome
array with approximately 17,000 recombinant proteins. Screening of
sera from healthy individuals, CRC from Indian origin, and CRC
from middle-east Asia origin were performed. Bio-statistical
analysis was performed to identify significant autoantibodies
altered. Pathway analysis was performed to explore the underlying
mechanism of the disease. **Results**The comprehensive proteomic
analysis revealed dysregulation of 15 panels of proteins including
CORO7, KCNAB1, WRAP53, NDUFS6, KRT30, and COLGALT2. Further
biological pathway analysis for the top dysregulated autoantigenic
proteins revealed perturbation in important biological pathways
such as ECM degradation and cytoskeletal remodeling etc.

Conclusions and Clinical RelevanceThe generation of an autoimmune
response against cancer-linked pathways could be linked to the
screening of the disease. The process of immune surveillance can
be detected at an early stage of cancer. Moreover, AAbs can be
easily extracted from blood serum through the least invasive test
for disease screening. [Barpanda, Abhilash; Tuckley, Chaitanya;

 Targeting HIF1-alpha/miR-326/ITGA5 axis potentiates
 chemotherapy response in triple-negative breast cancer BREAST
 CANCER RESEARCH AND TREATMENT English Article
 TNBC; miRNA-mRNA network;
 Chemoresistance; miR-326; Fibronectin; Integrin; Hypoxia; ECM
 stiffness CELL LUNG-CANCER; HYPOXIA; RESISTANCE; CARCINOMA;
 INVASION; PROLIFERATION; DOXORUBICIN; SURVIVAL; SEQUENCE; TUMORS

Purpose Triple-negative breast cancer (TNBC) is the most
 aggressive subtype of breast cancer that is frequently treated
 with chemotherapy. However, many patients exhibit either de novo
 chemoresistance or ultimately develop resistance to chemotherapy,
 leading to significantly high mortality rates. Therefore,
 increasing the efficacy of chemotherapy has potential to improve
 patient outcomes. Methods Here, we performed whole transcriptome
 sequencing (both RNA and small RNA-sequencing), coupled with
 network simulations and patient survival data analyses to build a
 novel miRNA-mRNA interaction network governing chemoresistance in
 TNBC. We performed cell proliferation assay, Western blotting,
 RNAi/miRNA mimic experiments, FN coating, 3D cultures, and ChIP
 assays to validate the interactions in the network, and their
 functional roles in chemoresistance. We developed xenograft models
 to test the therapeutic potential of the identified key
 miRNA/proteins in potentiating chemoresponse in vivo. We also
 analyzed several patient datasets to evaluate the clinical
 relevance of our findings. Results We identified fibronectin (FN1)
 as a central chemoresistance driver gene. Overexpressing miR-326
 reversed FN1-driven chemoresistance by targeting FN1 receptor,
 ITGA5. miR-326 was downregulated by increased hypoxia/HIF1A and
 ECM stiffness in chemoresistant tumors, leading to upregulation of
 ITGA5 and activation of the downstream FAK/Src signaling pathways.
 Overexpression of miR-326 or inhibition of ITGA5 overcame FN1-
 driven chemotherapy resistance in vitro by inhibiting FAK/Src
 pathway and potentiated the efficacy of chemotherapy in vivo.
 Importantly, lower expression of miR-326 or higher levels of
 predicted miR-326 target genes was significantly associated with
 worse overall survival in chemotherapy-treated TNBC patients.
 Conclusion FN1 is central in chemoresistance. In chemoresistant
 tumors, hypoxia and resulting ECM stiffness repress the expression
 of the tumor suppressor miRNA, miR-326. Hence, re-expression of
 miR-326 or inhibition of its target ITGA5 reverses FN1-driven
 chemoresistance making them attractive therapeutic approaches to
 enhance chemotherapy response in TNBCs. [Assidicky, Ridho; Tokat,

J Pandurangan, AK; Ganapasam, S Pandurangan, Ashok Kumar; Ganapasam, Sudhandiran Cytotoxic Effect of Luteolin on Human Colorectal Cancer Cell Line (HCT-15): Crucial Involvement of Reactive Oxygen Species MIDDLE EAST JOURNAL OF CANCER English Article Colon cancer; Luteolin; ROS; HCT-15 INDUCED APOPTOSIS; NITRIC-OXIDE;

INHIBITION; INDUCTION; KINASE Background: Colorectal cancer, a major health concern worldwide, is the third most common form of cancer and second leading cause of cancer-related deaths. The flavonoids are naturally occurring diphenylpropanoids ubiquitous in plant foods and important components of the human diet. Luteolin, a bioflavonoid, possesses many beneficial effects including antioxidant, anti-inflammatory, anti-allergic activities. Methods: We used the HCT-15 colon adenocarcinoma cell line in this study. Cells were treated with luteolin (100 μ M). Results: Membrane damage markers such as alkaline phosphatase and lactate dehydrogenase were analyzed in a time-dependent manner. Luteolin increased reactive oxygen species in a time-dependent manner. DNA damage, a hallmark of apoptosis, was induced by luteolin as analyzed by agarose gel electrophoresis. Conclusion: Luteolin acts as a potential cytotoxic agent that can be used to treat colorectal cancer. Effects of Pre-surgical Vitamin D Supplementation and Ketogenic Diet in a Patient with Recurrent Breast Cancer

ANTICANCER RESEARCH English Article

Vitamin D-3; ketogenic diet; breast cancer MONOUNSATURATED FATTY-ACID; SERUM 25-HYDROXYVITAMIN D; PROTEIN-KINASE-C; OLEIC-ACID; MEDITERRANEAN DIET; OLIVE OIL; CELLS; COMPLEXES; RISK; METAANALYSIS Background: A woman, mother of one at the age of 19 years, was diagnosed with mammary adenocarcinoma in the right breast in 1985 at the age of 37 years. The patient underwent surgery (quadrantectomy), lymphadenectomy and radiotherapy. In 1999, an adenocarcinoma was diagnosed in the left breast, followed by adequate resection, radiotherapy and anti-oestrogen receptor treatment for 6 years. In March 2014, an infiltrating adenocarcinoma was diagnosed in the remaining part of the right breast that had been operated on and irradiated in 1985. Case Report: The pre-surgical biopsy, showed weak positivity for progesterone receptor (PgR) (<1%), high positivity for oestrogen receptor (ER) (90%), high positivity for human epidermal growth factor receptor (HER2) (>10%, score 2+), and high positivity for the nuclear protein Ki67 (30%). In the three weeks between diagnosis and operation, when no other treatment had been planned, the patient decided to self-administer high doses of oral vitamin D-3 (10,000 IU/day), and to follow a strict ketogenic diet. Results: Following right mastectomy, analysis of the surgical specimen showed no positivity for HER2 expression (negative, score 0), and significant increase in positivity of PgR (20%). Positivity for ER and Ki67 were unaltered. Conclusion: This observation indicates that a combination of high-dose vitamin D-3

and ketogenic diet leads to changes in some biological markers of breast cancer, i.e. negativization of HER2 expression and increased expression of PgR. [Branca, Jacopo J. association study of treatment-related toxicity two years
following radiotherapy for breast cancer RADIOTHERAPY AND
ONCOLOGY English Article

Radiogenomics; Genome-wide association study; Chronic toxicity; Radiotherapy side effects; Radiotherapy; Breast Cancer RADIATION; POLYMORPHISMS; DERMATITIS; GENES; RISK; GWAS

Background and purpose: Up to a quarter of breast cancer patients treated by surgery and radiotherapy experience clinically significant toxicity. If patients at high risk of adverse effects could be identified at diagnosis, their treatment could be tailored accordingly. This study was designed to identify common single nucleotide polymorphisms (SNPs) associated with toxicity two years following whole breast radiotherapy. Materials and Methods: A genome-wide association study (GWAS) was performed in 1,640 breast cancer patients with complete SNP, clinical, treatment and toxicity data, recruited across 18 European and US centres into the prospective REQUITE cohort study. Toxicity data (CTCAE v4.0) were collected at baseline, end of radiotherapy, and

annual follow-up. A total of 7,097,340 SNPs were tested for association with the residuals of toxicity endpoints, adjusted for clinical, treatment co-variables and population substructure. Results: Quantile-quantile plots showed more associations with toxicity above the $p = 5 \times 10^{-5}$ level than expected by chance. Eight SNPs reached genome-wide significance. Nipple retraction grade 2 was associated with the rs188287402 variant ($p = 2.80 \times 10^{-8}$), breastoedema grade > 2 with rs12657177 ($p = 1.12 \times 10^{-10}$), rs75912034 ($p = 1.12 \times 10^{-10}$), rs145328458 ($p = 1.06 \times 10^{-9}$) and rs61966612 ($p = 1.23 \times 10^{-9}$), induration grade > 2 with rs77311050 ($p = 2.54 \times 10^{-8}$) and rs34063419 ($p = 1.21 \times 10^{-8}$), and arm lymphoedema grade > 1 with rs643644 ($p = 3.54 \times 10^{-8}$). Heritability estimates across significant endpoints ranged from 25% to 39%. Our study did not replicate previously reported SNPs associated with breast radiation toxicity at the pre-specified significance level. Conclusions: This GWAS for long-term breast radiation toxicity provides further evidence for significant association of common SNPs with distinct toxicity endpoints. (c) 2023 The Authors. GBD 2015 Eastern Mediterranean Reg Burden of cancer in the Eastern Mediterranean Region, 2005–2015: findings from the Global Burden of Disease 2015 Study INTERNATIONAL JOURNAL OF PUBLIC HEALTH English Article

Eastern Mediterranean Region; Cancer; Mortality; Incidence; Disability-adjusted life years DEATH To estimate incidence, mortality, and disability-adjusted life years (DALYs) caused by cancer in the Eastern Mediterranean Region (EMR) between 2005 and 2015. Vital registration system and cancer registry data from the EMR region were analyzed for 29 cancer groups in 22 EMR countries using the Global Burden of Disease Study 2015 methodology. In 2015, cancer was responsible for 9.4% of all deaths and 5.1% of all DALYs. It accounted for 722,646 new cases, 379,093 deaths, and 11.7 million DALYs. Between 2005 and 2015, incident cases increased by 46%, deaths by 33%, and DALYs by 31%. The increase in cancer incidence was largely driven by population growth and population aging. Breast cancer, lung cancer, and leukemia were the most common cancers, while lung, breast, and stomach cancers caused most cancer deaths. Cancer is responsible for a substantial disease burden in the EMR, which is increasing. There is an urgent need to expand cancer prevention, screening, and awareness programs in EMR countries as well as to improve diagnosis, treatment, and palliative care services. MIGRATION LETTERS English Article Foreign population; immigration; residential segregation; metropolitan space; Italy NON-EUROPEAN MIGRANTS; NEIGHBORHOOD CONCENTRATION; FAMILY; REPRESENTATION; MIGRATION; PATTERNS Southern European studies of migrants' spatial distribution within metropolitan cities (MCs) are increasingly relevant to understanding residential segregation and marginalisation, particularly of foreign nationals. This paper leverages original and partially unpublished data to examine overall and foreign national specific segregation over two decades in Rome MC and Milan MC, the two largest Italian MCs. We introduce a 5-class concentric ring typology to describe and uncover geographical patterns within the Mu and focus on the spatial and temporal distribution of four selected foreign nationalities: Romanian, Bangladeshi, Chinese, and Filipino. Results reveal heterogeneity in overall and foreign national specific distributions over time both within and between Rome MC and Milan MC. Comparing across groups and MCs we identify similarities but also unique patterns. These results shed light on the peculiarity of the urban demographic Italian landscape and raise questions regarding recent theories about residential segregation in the urban contexts of Southern Europe. gynaecological malignancies in Egypt (1999-2002) BJOG-AN

INTERNATIONAL JOURNAL OF OBSTETRICS AND GYNAECOLOGY

English Article Egypt;

gynaecologic cancers; urban-rural; xenoestrogens PERSISTENT ORGANIC POLLUTANTS; ENDOMETRIAL CANCER RISK; BISPHENOL-A; OVARIAN-CANCER; BREAST-CANCER; EPIDEMIOLOGY; PESTICIDES; RECEPTOR; HISTORY; UTERINE Objective In previous studies, we have shown a three to four times higher urban incidence of breast cancer and estrogen receptor-positive breast cancers in the Gharbiah Province of Egypt. We investigated the urban-rural incidence differences of gynaecologic malignancies (uterine, ovarian and cervical cancers) to explore if they show the same trend that we found for breast

cancer. Design Cancer registry-based incidence comparison. Setting Gharbiah population-based cancer registry (GPCR), Tanta, Egypt. Sample All patients with uterine, ovarian and cervical cancer in GPCR from 1999 to 2002. Methods We calculated uterine, ovarian and cervical cancer incidence from 1999 to 2002. For each of the three cancers, we calculated the overall and age-specific rates for the province as a whole, and by urban-rural status, as well as for the eight districts of the province. Results Incidence of all three cancer sites was higher in urban than in rural areas. Uterine cancer showed the highest urban-rural incidence rate ratio (IRR = 6.07, 95% CI = 4.17, 8.85). Uterine cancer also showed the highest urban incidence in the oldest age group (70+ age category, IRR = 14.39, 95% CI = 4.24, 48.87) and in developed districts (Tanta, IRR = 4.14, 95% CI = 0.41, 42.04). Incidence rates by groups of cancer sites showed an increasing gradient of urban incidence for cancers related to hormonal aetiology, mainly of the breast and uterus (IRR = 4.96, 95% CI = 2.86, 8.61). Conclusions The higher urban incidence of uterine cancer, coupled with our previous findings of higher incidence of breast cancer and estrogen receptor positive breast cancer in urban areas in this region, may be suggestive of possible higher exposure to environmental estrogenic compounds, such as xenoestrogens, in urban areas.

Physical activity and Mediterranean diet as potential modulators of osteoprotegerin and soluble RANKL in gBRCA1/2 mutation carriers: results of the lifestyle intervention pilot study LIBRE-1 BREAST CANCER RESEARCH AND TREATMENT

English Article BRCA1; 2
mutation carriers; Breast cancer; OPG; RANKL; Lifestyle intervention; Physical activity; Mediterranean diet; Fatty acids N-3 FATTY-ACIDS; KAPPA-B LIGAND; BREAST-CANCER RISK; RECEPTOR ACTIVATOR; SERUM OSTEOPROTEGERIN; DOCOSAHEXAENOIC ACID; RESISTANCE EXERCISE; AEROBIC EXERCISE; BRCA1 MUTATION; STEM-CELLS

Purpose Emerging evidence suggests that the progesterone-mediated receptor activator of nuclear factor kappa B (RANK)/soluble RANK ligand (sRANKL)/osteoprotegerin (OPG) pathway plays an important role in mammary carcinogenesis and is hyperactivated in germline (g)BRCA1/2 mutation carriers. We analyzed the effects of a 3-month intensive lifestyle intervention within the LIBRE-1 study on the serum levels of OPG and sRANKL and hypothesized that the intervention program provides a beneficial impact on the biomarkers by increasing OPG and reducing sRANKL serum concentrations. Methods Serum levels of OPG and sRANKL of 49 gBRCA1/2 mutation carriers were quantified using enzyme-linked immunosorbent assays. We used previously collected blood samples from participants of the prospective LIBRE-1 study, who were randomized into an intervention group (IG), increasing physical activity and adherence to the Mediterranean diet (MedD) through supervised sessions from study entry to the first study visit after 3 months and a usual-care control group (CG). Differences in biomarker levels before and after the 3-month intervention were tested within and between study groups. Results The lifestyle intervention resulted in a significant increase in OPG for participants in both the IG ($q = 0.022$) and CG ($q = 0.002$). sRANKL decreased significantly in the IG ($q = 0.0464$) and seemed to decrease in the CG ($q = 0.5584$). An increase in the intake of Omega-3 polyunsaturated fatty acids was significantly associated

with an increase in OPG ($r = 0.579$, $q = 0.045$). Baseline serum levels of sRANKL were a strong predictor for the change of sRANKL in the course of the intervention (ss-estimate = -0.70 ; $q = 0.0018$). Baseline physical fitness (assessed as $VO(2)_{peak}$) might predict the change of OPG in the course of the intervention program (ss-estimate = 0.133 pg/ml/ml/min/kg; $p = 0.0319$; $q = 0.2871$). Conclusion Findings from this pilot study seem to confirm our hypothesis by showing an increase in OPG and decrease in sRANKL over a 3-month lifestyle intervention and suggest that increased physical activity and adherence to the MedD are potent modulators of the biomarkers OPG and potentially sRANKL.  High-Quality Diets Associate With Reduced Risk of Colorectal
 Cancer: Analyses of Diet Quality Indexes in the Multiethnic Cohort
 GASTROENTEROLOGY English Article
 DASH; Food; Nutrition; Colon Cancer
 MAJOR CHRONIC DISEASE; HEALTHY EATING INDEX; GUIDELINES-FOR-
 AMERICANS; PATTERNS; MORTALITY; ADHERENCE; WOMEN; SURVIVAL;
 HAWAII; FIBER BACKGROUND & AIMS: Healthy eating patterns
 assessed by diet quality indexes (DQIs) have been related to lower
 risk of colorectal cancer-mostly among whites. We investigated the
 associations between 4 DQI scores (the Healthy Eating Index 2010
 [HEI-2010], the Alternative Healthy Eating Index 2010 [AHEI-2010],
 the alternate Mediterranean diet score [aMED], and the Dietary
 Approaches to Stop Hypertension score) and colorectal cancer risk
 in the Multiethnic Cohort. METHODS: We analyzed data from 190,949
 African American, Native Hawaiian, Japanese American, Latino, and
 white individuals, 45 to 75 years old, who entered the Multiethnic
 Cohort study from 1993 through 1996. During an average 16 years of
 follow-up, 4770 invasive colorectal cancer cases were identified.
 RESULTS: Scores from all 4 DQIs associated inversely with
 colorectal cancer risk; higher scores associated with decreasing
 colorectal cancer risk (all P's for trend $\leq .003$). Associations
 were not significant for AHEI-2010 and aMED scores in women after
 adjustment for covariates: for the highest vs lowest quintiles,
 the hazard ratio for the HEI-2010 score in men was 0.69 (95%
 confidence interval [CI], 0.59-0.80) and in women was 0.82 (95%
 CI, 0.70-0.96); for the AHEI-2010 score the hazard ratio in men
 was 0.75 (95% CI, 0.65-0.85) and in women was 0.90 (95% CI, 0.78-
 1.04); for the aMED score the hazard ratio in men was 0.84 (95%
 CI, 0.73-0.97) and in women was 0.96 (95% CI, 0.82-1.13); for the
 Dietary Approaches to Stop Hypertension score the hazard ratio in
 men was 0.75 (95% CI, 0.66-0.86) and in women was 0.86 (95% CI,
 0.75-1.00). Associations were limited to the left colon and rectum
 for all indexes. The inverse associations were less strong in
 African American individuals than in the other 4 racial/ethnic
 groups. CONCLUSIONS: Based on an analysis of data from the
 Multiethnic Cohort Study, high-quality diets are associated with a
 lower risk of colorectal cancer in most racial/ethnic subgroups.

Can Dietary Iron Bioavailability Influence Colorectal
Cancer Risk and Prognosis? MIDDLE EAST JOURNAL OF CANCER

English Article

Colorectal neoplasms; Dietary iron; Biological availability;
Hepcidins; Projections and predictions DOSE-RESPONSE

METAANALYSIS; ONE-CARBON METABOLISM; PHYTIC ACID; VITAMIN-B12;

ABSORPTION; ANEMIA; ASSOCIATION; PREVENTION; PREDICTION; HEPCIDIN

Colorectal cancer (CRC) stands apart from other malignancies due to its pronounced association with dietary patterns.

Approximately 70% of all CRC cases arise sporadically, and suboptimal dietary and lifestyle choices can override certain predisposing factors, including a family history of the disease. Hitherto, the most compelling evidence linking CRC risk has been attributed to heme iron, predominantly found in red and processed meats, although this form of iron constitutes a mere 20% of total dietary iron. The human organism maintains a remarkably intricate and tightly regulated iron homeostasis system owing to the deleterious consequences of both excessive and deficient serum iron levels. Dietary sources remain the sole means to replenish iron losses. Despite the abundant presence of iron in various food sources, its absorption, commonly referred to as bioavailability, is notably restricted due to an array of dietary inhibitors and homeostatic mechanisms. Consequently, a substantial 80% of ingested dietary iron is excreted in fecal matter, resulting in fecal iron concentrations that surpass those found in most body tissues by a tenfold margin. Prolonged exposure of the colorectum to excessive fecal iron, combined with concurrent physiological alterations, can instigate oncogenic processes leading to CRC. Notably, despite their recognized significance in CRC pathology, dietary habits, and lifestyle factors have been sporadically integrated into predictive models, primarily concerning CRC recurrence. Nonetheless, these models exhibit disparities in the dietary components, rendering them non-universally applicable. In light of these disparities, postulating that incorporating bioavailable iron, in conjunction with hepcidin levels, may offer superior predictive value for CRC risk assessment, and herein, elucidates the scientific foundation supporting this hypothesis.

cardiovascular disease risk among breast cancer survivors in the Pathways Study JNCI CANCER SPECTRUM English

Article CORONARY-HEART-DISEASE; MORTALITY; ADHERENCE; PATTERNS Background Women with

breast cancer are at higher risk of cardiovascular disease (CVD) compared with women without breast cancer. Whether higher diet quality at breast cancer diagnosis lowers this risk remains unknown. We set out to determine if higher diet quality at breast cancer diagnosis was related to lower risk of CVD and CVD-related death. Methods This analysis included 3415 participants from the Pathway Study, a prospective cohort of women diagnosed with invasive breast cancer at Kaiser Permanente Northern California between 2005 and 2013 and followed through December 31, 2021.

Scores from 5 diet quality indices consistent with healthy eating were obtained at the time of breast cancer diagnosis. Scores were categorized into ascending quartiles of concordance for each diet quality index, and multivariable adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated. P values were 2-sided. Results The Dietary Approaches to Stop Hypertension diet quality index was associated with lower risk of heart failure (HR = 0.53, 95% CI = 0.33 to 0.87; Ptrend = .03), arrhythmia (HR = 0.77, 95% CI = 0.62 to 0.94; Ptrend = .008), cardiac arrest (HR = 0.77, 95% CI = 0.61 to 0.96; Ptrend = .02), valvular heart disease (HR = 0.79, 95% CI = 0.64 to 0.98; Ptrend = .046), venous thromboembolic disease (HR = 0.75, 95% CI = 0.60 to 0.93; Ptrend = .01), and CVD-related death (HR = 0.70, 95% CI = 0.50 to 0.99; Ptrend = .04), when comparing the highest with lowest quartiles.

Inverse associations were also found between the healthy plant-based dietary index and heart failure (HR = 0.60, 95% CI = 0.39 to 0.94; Ptrend = .02), as well as the alternate Mediterranean dietary index and arrhythmia (HR = 0.74, 95% CI = 0.60 to 0.93; Ptrend = .02). Conclusion Among newly diagnosed breast cancer patients, higher diet quality at diagnosis was associated with

lower risk of CVD events and death. Sch.Bip Flower Dichloromethane Extract Exerts Anti-Proliferative and Pro-Apoptotic Properties in Human Triple-Negative Breast Cancer (MDA-MB-231) Cells: In Vitro and In Silico Studies

PHARMACEUTICALS English Article

Achillea fragrantissima; carbonic anhydrase; caspase activation; mitochondrial apoptosis pathway; triple-negative breast cancer CARBONIC-ANHYDRASE IX; NATURAL-PRODUCTS; CONSTITUENTS; EXPRESSION; INHIBITION; QUERCETIN; DISCOVERY; TUBULIN; BINDING; PLANTS The aggressive triple-negative breast cancer (TNBC) is a challenging disease due to the absence of tailored therapy. The search for new therapies involves intensive research focusing on natural sources. Achillea fragrantissima (A. fragrantissima) is a traditional medicine from the Middle East region. Various solvent extracts from different A. fragrantissima plant parts, including flowers, leaves, and roots, were tested on TNBC MDA-MB-231 cells. Using liquid chromatography, the fingerprinting revealed rich and diverse compositions for A. fragrantissima plant parts using polar to non-polar solvent extracts indicating possible differences in bioactivities. Using the CellTiter-Glo (TM) viability assay, the half-maximal inhibitory concentration (IC50) values were determined for each

extract and ranged from 32.4 to 161.7 μ g/mL. The A. fragrantissima flower dichloromethane extract had the lowest mean IC50 value and was chosen for further investigation. Upon treatment with increasing A. fragrantissima flower dichloromethane extract concentrations, the MDA-MB-231 cells displayed, in a dose-dependent manner, enhanced morphological and biochemical hallmarks of apoptosis, including cell shrinkage, phosphatidylserine exposure, caspase activity, and mitochondrial outer membrane permeabilization, assessed using phase-contrast microscopy, fluorescence-activated single-cell sorting analysis, Image-iT (TM) live caspase, and mitochondrial transition pore opening activity, respectively. Anticancer target prediction and molecular docking studies revealed the inhibitory activity of a few A. fragrantissima flower dichloromethane extract-derived metabolites against carbonic anhydrase IX, an enzyme reported for its anti-apoptotic properties. In conclusion, these findings suggest promising therapeutic values of the A. fragrantissima flower dichloromethane extract against TNBC development. Development of exchange lists for Mediterranean and Healthy Eating Diets: implementation in an intervention trial JOURNAL OF HUMAN NUTRITION AND DIETETICS English Article

Mediterranean diet; modified exchange lists; overweight; telephone counselling COLORECTAL-CANCER; CARDIOVASCULAR RISK; RANDOMIZED-TRIAL; VEGETABLE INTAKE; FATTY-ACIDS; COLON CARCINOGENESIS; METABOLIC SYNDROME; BREAST-CANCER; BODY-WEIGHT; STYLE DIET Background: There has been little research published on the adaptation of diabetic exchange list diet approaches for the design of intervention diets in health research despite their clinical utility. The exchange list approach can provide clear and precise guidance on multiple dietary changes simultaneously. The present study aimed to develop exchange list diets for Mediterranean and Healthy Eating, and to evaluate adherence, dietary intakes and markers of health risks with each counselling approach in 120 subjects at increased risk for developing colon cancer. Methods: A randomised clinical trial was implemented in the USA involving telephone counselling. The Mediterranean diet had 10 dietary goals targeting increases in mono-unsaturated fats, n-3 fats, whole grains and the amount and variety of fruits and vegetables. The Healthy Eating diet had five dietary goals that were based on the US Healthy People 2010 recommendations. Results: Dietary compliance was similar in both diet arms, with 82-88% of goals being met at 6 months, although subjects took more time to achieve the Mediterranean goals than the Healthy Eating goals. The relatively modest fruit and vegetable goals in the Healthy Eating arm were exceeded, resulting in fruit and vegetable intakes of approximately eight servings per day in each arm after 6 months. A significant ($P < 0.05$) weight

loss and a decrease in serum C-reactive protein concentrations were observed in the overweight/obese subgroup of subjects in the Mediterranean arm in the absence of weight loss goals.

Conclusions: Counselling for the Mediterranean diet may be useful for both improving diet quality and for achieving a modest weight loss in overweight or obese individuals. [Sidahmed, E.;

Antioxidant Capacity and Cytotoxicity of Aesculus hippocastanum on Breast Cancer MCF-7 Cells JOURNAL OF FOOD AND DRUG ANALYSIS English Article

Aesculus hippocastanum L.; antioxidant capacity; cytotoxicity; MCF-7 CHRONIC VENOUS INSUFFICIENCY; RETRACTED ARTICLE. SEE; HORSE CHESTNUT EXTRACT; BETA-ESCLIN; ENDOTHELIAL-

CELLS; PROLIFERATION; AESCIN; APOPTOSIS; FLAVONOIDS; ASSAY

Aesculus hippocastanum L. is a native tree of Asia. Its leaves, seeds and flowers have long been used in folk medicine and in traditional food ingredients. In this study, the bark, seeds, leaves and flowers as aerial parts of *A. hippocastanum* were extracted in ethanol. The antioxidant capacity of each part was determined for its 1,1-diphenyl-2-picrylhydrazyl radical (DPPH) scavenging capacity, microsomal lipid peroxidation inhibition capacity and total phenolic content. Among all the parts examined, the bark extract of *A. hippocastanum* revealed the highest antioxidant capacity with an IC₅₀ value of 0.025 mg/mL and 0.014 mg/mL for the inhibition of lipid peroxidation and for the scavenging of DPPH radical, respectively. The bark extract was further examined for its cytotoxic effect on human breast cancer cells (MCF-7) and on healthy cells (3T3) using the MTT method. Cell viability was reduced to 30% upon the addition of 0.5 mg/mL bark extract for both cell lines. J Costarelli, V; Michou, M Costarelli, Vassiliki; Michou, Maria Predictors of COVID-19 vaccine hesitancy and prevention practice in Greece

INTERNATIONAL JOURNAL OF HEALTH PROMOTION AND EDUCATION
English Article

COVID-19 vaccination; prevention; health literacy; Greece
HEALTH LITERACY; LIFE SATISFACTION; PERCEIVED STRESS; GLOBAL

MEASURE; ADULTS Achieving high COVID-19 vaccination rates globally is a key public health challenge. The study aims to investigate factors determining COVID-19 vaccine hesitancy and adherence to prevention measures, in Greek adults. This cross-sectional study was conducted in Greece, from the 21st of February to the 3rd of April 2021, during the strict lockdown period of the 3rd COVID-19 wave. A total of 2029 adults (75.3% women, median age 38 years) participated in an online survey. Participants completed a questionnaire assessing sociodemographic and anthropometric characteristics, adherence to COVID-19 prevention measures and willingness to vaccinate. Health Literacy (HL), perceived stress, life satisfaction and adherence to Mediterranean Diet (MD) were also assessed. Multiple linear and logistic regression analyses were employed. The median score of COVID-19 adherence to the prevention measures tool was 23.08 (interquartile range: 3.83; range: 1 to 35). A total of 57.5% of the participants were willing to vaccinate, 12.1% were unwilling and 30.4% were undecided. Linear regression revealed that women, obese participants, those with a chronic disease and those willing to vaccinate reported higher adherence to prevention measures. Older age, higher levels of HL, life satisfaction and adherence to MD were also positively associated with higher adherence. Logistic regression revealed that being a woman decreases the odds of having the willingness to vaccinate, whereas older age, higher education and adherence to measures increase the odds of willingness to vaccinate. The results could be used by practitioners, researchers and policy makers working in the field of prevention and management of COVID-19. J Jauhiainen, JS; Vorobeva, E Jauhiainen,
Jussi S.; Vorobeva, Ekaterina Syrian refugees and
other Syrian forced migrants in Jordan: forms of capital approach
BRITISH JOURNAL OF MIDDLE EASTERN STUDIES
English Article

SOCIAL IDENTITY; IMMIGRANT The article explored human, social, and economic capital of Syrian refugees and other Syrian forced migrants in Jordan. Interrelations of their human, social, and economic forms of capital affected their everyday lives in Jordan as well as their future migration aspirations. The data consisted of a semi-structured survey among 408 Syrian refugees and other forced Syrian migrants in Jordan. Varied combinations of these forms of capital significantly impacted the well-being of these Syrians in the host state. Those who consolidated human capital and possessed dispersed and open social networks created

coping strategies through education and employment that were more likely to be effective, and they considered immigrating to countries that are more developed. Syrians who lacked capital stocks in Jordan often found themselves at the risk of poverty, immobility or forced return to their ruined livelihoods in Syria. The article debunked the myth about powerlessness and passiveness of refugees and other forced migrants and drew attention to their agency and assets. Their levels of vulnerability in the host country significantly varied among individuals with different capital stocks. The authors provided policy recommendations on empowerment of these increasingly vulnerable migrants.

Qusa, Mohammed H.; Siddique, Abu Bakar; Nazzal, Sami; El Sayed, Khalid A. Novel olive oil phenolic (-)-oleocanthal (+)-xylitol-based solid dispersion formulations with potent oral anti-breast cancer activities INTERNATIONAL JOURNAL OF PHARMACEUTICS English Article

Extra-virgin olive oil; c-MET receptor tyrosine kinase; (-)-Oleocanthal; Solid dispersion; Taste masking; (+)-Xylitol ELECTRONIC TONGUE; IN-VITRO; STATE CHARACTERIZATION; MEDITERRANEAN DIET; DISSOLUTION RATE; C-MET; XYLITOL; OLEOCANTHAL; SOLUBILITY; EXPRESSION Epidemiological studies have compellingly documented the ability of the Mediterranean diet rich in extra-virgin olive oil to reduce the incidence of certain malignancies, and cardiovascular diseases, and slow the Alzheimer's disease progression. S-(-)-Oleocanthal (OC) was identified as the most bioactive olive oil phenolic with documented anti-inflammatory, anticancer, and anti-Alzheimer's activities. OC consumption causes irritating sensation at the oropharynx via activation of TRPA1. Accordingly, a taste-masked formulation of OC is needed for its future use as a nutraceutical while maintaining its bioactivity and unique chemistry. Therefore, the goal of this study was to prepare a taste-masked OC solid formulation with improved dissolution and pharmacodynamic profiles, by using (+)-xylitol as an inert carrier. Xylitol was hypothesized to serve as an ideal

vehicle for the preparation of OC solid dispersions due to its low melting point and sweetness. The optimized OC-(+)-xylitol solid dispersion was physically and chemically characterized and showed effective taste masking and enhanced dissolution properties. Furthermore, OC-(+)-xylitol solid dispersion maintained potent in vivo anti-breast cancer activity. It effectively suppressed the human triple negative breast cancer development, growth, and recurrence after primary tumor surgical excision in nude mice orthotopic xenograft models. Collectively, these results suggest the OC-(+)-xylitol solid dispersion formulation as a potential nutraceutical for effective control and prevention of human triple negative breast cancer.

THE MULTIDRUG-RESISTANCE (MDR) GENE IN BREAST-CANCER JOURNAL
OF CHEMOTHERAPY English Article; Proceedings Paper

9th Mediterranean Congress of Chemotherapy JUN, 1994

MILAN, ITALY BREAST CANCER; ONCOGENE;

MULTIPLE DRUG RESISTANCE Of the approximately 18,000 new cases of cancer in Venezuela each year, only half can be treated with surgery and radiation. The remainder must be treated systematically using chemotherapy or biological response modifiers. It has become evident that any drug resistant human tumors express the MDR1 gene, since MDR1 RNA levels are elevated in many cancers that do not respond to chemotherapy. Human mammary carcinomas have multiple oncogene alterations, the most frequently reported being overexpression of the oncogenes c-myc, int-2, neu and C-myb. Thirteen specimens of mammary cancer were obtained by

biopsy of untreated patients in stage IIIB. All these patients received three cycles of FAC or CMF-L + GM-CSF after biopsy. In the slot blot analysis of RNA from invasive carcinomas, MDR1 and c-myc transcripts were detectable at a high level in 30% of tumors. Two patients with increased levels of MDR1 before chemotherapy did not respond to the treatment and distant metastasis and death occurred in these patients. Another patient, MDR1-negative before therapy, did not respond to CMF-I + GM-CSF and showed high levels of MDR1 transcripts in a second biopsy which was obtained during surgery.

Hlth Fdn Study Grp The burden of breast cancer in Italy:
mastectomies and quadrantectomies performed between 2001 and 2008
based on nationwide hospital discharge records JOURNAL OF
EXPERIMENTAL & CLINICAL CANCER RESEARCH English

Article Hospital discharge
records; Breast cancer; Mastectomies; Quadrantectomies; Cancer
surveillance MEDICARE CLAIMS; REGISTRY DATA; DISEASE

Background: Where population coverage is limited, the
exclusive use of Cancer Registries might limit ascertainment of
incident cancer cases. We explored the potentials of Nationwide
hospital discharge records (NHDRs) to capture incident breast
cancer cases in Italy. Methods: We analyzed NHDRs for mastectomies
and quadrantectomies performed between 2001 and 2008. The average
annual percentage change (AAPC) and related 95% Confidence
Interval (CI) in the actual number of mastectomies and
quadrantectomies performed during the study period were computed
for the full sample and for subgroups defined by age, surgical
procedure, macro-area and singular Region. Re-admissions of the
same patients were separately presented. Results: The overall
number of mastectomies decreased, with an AAPC of -2.1% (-2.3 -
-1.8). This result was largely driven by the values observed for
women in the 45 to 64 and 65 to 74 age subgroups (-3.0%, -3.4 -3.6
and -3.3%, -3.8 -2.8, respectively). We observed no significant
reduction in mastectomies for women in the remaining age groups.
Quadrantectomies showed an overall +4.7 AAPC (95%CI:4.5-4.9), with

no substantial differences by age. Analyses by geographical area showed a remarkable decrease in mastectomies, with inter-regional discrepancies possibly depending upon variability in mammography screening coverage and adherence. Quadrantectomies significantly increased, with Southern Regions presenting the highest average rates. Data on repeat admissions within a year revealed a total number of 46,610 major breast surgeries between 2001 and 2008, with an overall +3.2% AAPC (95%CI:2.8-3.6). Conclusions: In Italy, NHDRs might represent a valuable supplemental data source to integrate Cancer Registries in cancer surveillance.

Modulations of the Bcl-2/Bax family were involved
in the chemopreventive effects of licorice root (*Glycyrrhiza
uralensis fisch*) in MCF-7 human breast cancer cell JOURNAL OF
AGRICULTURAL AND FOOD CHEMISTRY English Article

licorice; MCF-7 cell; Bcl-2;
Bax; PARP; apoptosis CYCLE ARREST; APOPTOSIS; PHOSPHORYLATION;
CONSTITUENTS; CAPACITY; LDL Recently, cancer chemoprevention with
strategies using foods and medicinal herbs has been regarded as
one of the most visible fields for cancer control. Genistein in
soy, American ginseng, and resveratrol are well-known to have
antiproliferative properties in human breast cancer. Licorice root
is a botanical, a shrub native to southern Europe and Asia, which
primarily has desirable qualities in sweetening and herbal
medicine. In this study, licorice (*Glycyrrhiza uralensis Fisch*)
root also inhibits cell proliferation in human breast cancer cell.
The cell proliferation study demonstrated that licorice root
reduced the proliferation of MCF-7 cells in a dose- and time-
dependent manner. The extracts were fractionated in CHCl₃, EtOAc,
C₆H₁₄, and CH₃OH-H₂O (70:30), and these extracts of licorice root
(50 µg/mL) induced DNA fragmentation demonstrated by Hoechst
33258 staining. Apoptosis also determined the sub-G₁ accumulation
by flow cytometry analysis. These results were consistent with
specific cleavage of PARP and antiapoptotic protein Bcl-2 and up-
regulation of proapoptotic protein Bax demonstrated by Western
blotting. Our findings suggest that licorice root may have
chemopreventive effects against human breast cancer through the
modulation of the expression of the Bcl-2/ Bax family of apoptotic
regulatory factors. Seoul Natl Univ, Coll Vet Med, Dept Vet

Dietary inflammatory index and odds of colorectal
cancer in a case-control study from Jordan APPLIED PHYSIOLOGY
NUTRITION AND METABOLISM English Article
diet; cytokines; nutrition;
inflammation; epidemiology; dietary inflammatory index SOCIAL
DESIRABILITY BIAS; SELF-REPORT; ENERGY-INTAKE; RISK; ASSOCIATION;
VALIDATION; COMPROMISE; BIOMARKERS; VALIDITY; NSAIDS Dietary
components that promote inflammation of the colon have been
suggested to be risk factors in the development of colorectal
cancer (CRC). The possible link between inflammatory potential of
diet and CRC has been investigated in several developed or Western
countries. Despite the fact that dietary choices in the Middle
East differ markedly from those in the West, results have not been
reported from any study conducted in a Middle-Eastern population.
We examined the association between dietary inflammatory index
(DII) scores and CRC in a case-control study conducted in Jordan.
This study included 153 histopathologically confirmed CRC cases
and 202 disease-free control subjects' frequency matched on age,
sex, and occupation. Data were collected between January 2010 and
December 2012, using interviewer-administered questionnaires. DII
scores were computed from dietary data reported using a food
frequency questionnaire. Logistic regression models were used to
estimate odds ratios (ORs) and 95% confidence intervals (CIs)
adjusted for age, sex, education, physical activity, body mass
index, smoking, and family history of CRC. Subjects with higher
DII scores were at increased odds of CRC, with the DII being used
both as a continuous variable (OR_{continuous} = 1.45, 95% CI: 1.13-
1.85; 1-unit increase corresponding to approximate to 20% of its
range in the current study) and as a categorical variable
(OR_{tertile 3 vs tertile 1} = 2.13, 95% CI: 1.23-3.72). Our results,
based on a Jordanian population, add to the growing literature
indicating that a pro-inflammatory diet is associated with
increased odds of CRC. [Shivappa, Nitin; Hebert, James R.] Univ

Disease burden of osteoporosis and other non-communicable
diseases in Lebanon OSTEOPOROSIS INTERNATIONAL

English Article Hip
fractures; Osteoporosis; Major osteoporotic fractures; Middle
East; Non-communicable diseases POSTMENOPAUSAL WOMEN; VERTEBRAL
FRACTURES; PREVALENCE; OLDER; DIAGNOSIS; CANCER; MANAGEMENT;
MORTALITY; DENSITY; IMPACT Osteoporosis is more common than most
feared non-communicable diseases in the Middle East. This
justifies the need to place osteoporosis as a health priority in
the region. Introduction Osteoporosis is a common disease
associated with severe debilitating consequences. The objective of
this study is To evaluate and compare disease burden from
osteoporosis and other non-communicable diseases (NCDs) in
Lebanon. Methods We assessed the prevalence of osteoporosis and

other NCDs, such as obesity, diabetes, hypertension, dyslipidemia, and cardiovascular diseases, based on a published population-based study of Lebanese ≥ 65 years. We compared incidence rates of hip fractures and major osteoporotic fractures (MOF) (spine, hip, humerus, and forearm) to the five commonest cancers in women ≥ 50 years. Rates were based on the national hip fracture and cancer registry data, provided by the Lebanese Ministry of Public Health. MOF incidence rates were derived from national hip fracture incidence rates and MOF/hip fractures incidence rate ratios from the literature. Results Over 70% of elderly Lebanese had osteoporosis defined by densitometric criteria or prevalent morphometric vertebral fractures. This by far exceeded the prevalence of other NCDs, such as hypertension (53%), diabetes (21%), dyslipidemia (31%), and cardiovascular diseases (30%). Morphometric vertebral fractures (grades 2 and 3) were present in 19% of women and 12% of men. The incidence rates for MOF were 1.6 times greater than those for breast cancer, and 7.4-9.9 folds higher than those for the next commonest cancers of the lungs, colon, and ovaries. Hip fracture incidence rates were lower than those of breast cancer but were 2.1-2.8 folds higher than those of the above-mentioned cancers. Conclusion This first of its kind study in the Middle East demonstrates that osteoporosis is a common disease, more common than most feared NCDs. Our findings are comparable to those in western populations and justify placing osteoporosis on the top of NCDs' priority list in our country and possibly the region. Ly, Thanh Truong Giang; Yun, Jisoo; Lee, Dong-Hyung; Chung, Joo-Seop; Kwon, Sang-Mo Protective Effects and Benefits of Olive Oil and Its Extracts on Women's Health

olive oil; mediterranean diet; oleuropein; hydroxytyrosol; breast cancer; gynecologic cancer; osteoporosis; postmenopausal disorders CANCER CELL-PROLIFERATION; FATTY-ACID SYNTHASE; BREAST-CANCER; MEDITERRANEAN DIET; PHENOLIC-COMPOUNDS; BONE LOSS; ENDOTHELIAL FUNCTION; OVARIAN-CANCER; TRANSCRIPTION FACTORS; MOLECULAR-MECHANISMS Women and men share similar diseases; however, women have unique issues, including gynecologic diseases and diseases related to menstruation, menopause, and post menopause. In recent decades, scientists paid more attention to natural products and their derivatives because of their good tolerability and effectiveness in disease prevention and treatment. Olive oil is an essential component in the Mediterranean diet, a diet well known for its protective impact on human well-being. Investigation of the active components in olive oil, such as oleuropein and hydroxytyrosol, showed positive effects in various diseases. Their effects have been clarified in many suggested mechanisms and have shown promising results in animal and human studies, especially in breast cancer, ovarian cancer, postmenopausal osteoporosis, and other disorders. This review summarizes the current evidence of the role of olives and olive polyphenols in women's health issues and their potential implications in the treatment and prevention of health problems in women. Hydroxytyrosol decreases EDNRA expression through epigenetic modification in colorectal cancer cells PHARMACOLOGICAL RESEARCH

English Article

Hydroxytyrosol; DNA methylation; EDNRA; CpGs; Extra virgin olive oil; Caco-2 cells; Cancer VIRGIN OLIVE OIL; COLON; DIET

The Mediterranean diet (MD) is one of the healthiest ones and is associated with a lower incidence of cardio-vascular and cerebrovascular diseases as well as cancer. Extra virgin olive oil (EVOO) is probably the most idiosyncratic component of this diet. EVOO has been attributed with many healthful effects, which may be due to its phenolic components, e.g. including hydroxytyrosol (HT). Recent studies suggest that EVOO and HT have molecular targets in human tissues and modulate epigenetic mechanisms. DNA methylation is one of the most studied epigenetic mechanisms and consists of the addition of a methyl group to the cytosines of the DNA chain. Given the purported health effects of EVOO

(poly)phenols, we analyzed the changes induced by HT in DNA methylation, in a colorectal cancer cell line. Caco-2 cells were treated with HT for one week or with the demethylating agent 5'-azacytidine for 48 h. Global DNA methylation was assessed by ELISA. DNA bisulfitation was performed and Infinium Methylation EPIC BeadChips were used to analyze the specific methylation of CpG sites. We show an increase in global DNA methylation in Caco-2 cells after HT treatment, with a total of 32,141 differentially methylated (CpGs DMCpGs). Interestingly, our analyses revealed the endothelin receptor type A gene (EDNRA) as a possible molecular target of HT. In summary, we demonstrate that cellular supplementation with HT results in a specific methylome map and propose a potential gene target for HT. Survival of Middle Eastern and North African Individuals
 Diagnosed with Colorectal Cancer: A Population-Based Study in
 California CANCER EPIDEMIOLOGY BIOMARKERS & PREVENTION

English Article

SOCIOECONOMIC-STATUS; RACIAL DISPARITIES; MEDITERRANEAN
 DIET; UNITED-STATES; MORTALITY; HEALTH; ARAB; RACE; CARE;
 ASSOCIATIONBackground: Literature on colorectal cancer outcomes
 in individuals of Middle Eastern and North African (MENA) descent
 limited. To address this gap, we estimated five-year colorectal
 cancer-specific survival by race and ethnicity, including MENA
 individuals, in a diverse, population-based sample in California.
 Methods: We identified adults (ages 18-79 years) diagnosed with a
 first or only colorectal cancer in 2004 to 2017 using the
 California Cancer Registry (CCR), including non-Hispanic White,
 non-Hispanic Black, non-Hispanic Asian, Hispanic, and MENA indi-
 viduals. For each racial/ethnic group, we calculated five-year
 colo-rectal cancer-specific survival and used Cox proportional
 hazards regression models to examine the association of
 race/ethnicity and survival, adjusting for clinical and socio
 demographic factors. Results: Of 110,192 persons diagnosed with
 colorectal cancer, five-year colorectal cancer-specific survival
 was lowest in Black (61.0%) and highest in MENA (73.2%)
 individuals. Asian (72.2%) individuals had higher survival than
 White (70.0%) and Hispanic (68.2%) individuals. In adjusted
 analysis, MENA [adjusted HR (aHR), 0.82; 95% confidence interval
 (CI), 0.76-0.89], Asian (aHR, 0.86; 95% CI, 0.83-0.90), and
 Hispanic (aHR, 0.94; 95% CI, 0.91-0.97) race/ethnicity were
 associated with higher, and Black (aHR, 1.13; 95% CI, 1.09-1.18)
 race/ethnicity was associated with lower survival compared with
 non-Hispanic White race/ethnicity. Conclusions: To our knowledge,
 this is the first study to report colorectal cancer survival in
 MENA individuals in the United States. We observed higher survival
 of MENA individuals compared with other racial/ethnic groups,
 adjusting for sociodemographic and clinical factors. Impact:
 Future studies are needed to identify factors contributing to
 cancer outcomes in this unique population. [Zaki, Timothy A.]

J.; Khaw, K. T. Dietary patterns derived with multiple methods from food diaries and breast cancer risk in the UK Dietary Cohort Consortium EUROPEAN JOURNAL OF CLINICAL NUTRITION English Article
FAT; QUALITY; EATERS; INDEX
BACKGROUND/OBJECTIVES: In spite of several studies relating dietary patterns to breast cancer risk, evidence so far remains

inconsistent. This study aimed to investigate associations of dietary patterns derived with three different methods with breast cancer risk. SUBJECTS/METHODS: The Mediterranean Diet Score (MDS), principal components analyses (PCA) and reduced rank regression (RRR) were used to derive dietary patterns in a case-control study of 610 breast cancer cases and 1891 matched controls within four UK cohort studies. Dietary intakes were collected prospectively using 4-to 7-day food diaries and resulting food consumption data were grouped into 42 food groups. Conditional logistic regression models were used to estimate odds ratios (ORs) for associations between pattern scores and breast cancer risk adjusting for relevant covariates. A separate model was fitted for post-menopausal women only. RESULTS: The MDS was not associated with breast cancer risk (OR comparing first tertile with third 1.20 (95% CI 0.92; 1.56)), nor the first PCA-derived dietary pattern, explaining 2.7% of variation of diet and characterized by cheese, crisps and savoury snacks, legumes, nuts and seeds (OR 1.18 (95% CI 0.91; 1.53)). The first RRR-derived pattern, a 'high-alcohol' pattern, was associated with a higher risk of breast cancer (OR 1.27; 95% CI 1.00; 1.62), which was most pronounced in post-menopausal women (OR 1.46 (95% CI 1.08; 1.98)). CONCLUSIONS: A 'high-alcohol' dietary pattern derived with RRR was associated with an increased breast cancer risk; no evidence of associations of other dietary patterns with breast cancer risk was observed in this study.

Adherence to a Mediterranean-Style Dietary Pattern and Cancer Risk in a Prospective Cohort Study NUTRIENTS English Article

cancer; Mediterranean diet; diet patterns; cohort study; epidemiology BREAST-CANCER; COLORECTAL-CANCER; CARDIOVASCULAR RISK; METABOLIC SYNDROME; POOLED ANALYSIS; REPRODUCIBILITY; VALIDITY; IMPACT; WOMEN A Mediterranean-style diet is a healthy eating pattern that may benefit cancer risk, but evidence among Americans is scarce. We examined the prospective association between adherence to such a diet pattern and total cancer risk. A Mediterranean-style dietary pattern (MSDP) score was derived from a semi-quantitative food frequency questionnaire at exam 5 (1991-1995). Subjects included 2966 participants of the Framingham Offspring Study who were free of prevalent cancer. Cox proportional hazards regression models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs), adjusting for demographic, lifestyle, and anthropometric measures. Cox-models were also used to examine effect modification by lifestyle and anthropometric measures. During 18 years of median follow-up, 259 women and 352 men were diagnosed with cancer. Women with moderate or higher adherence to the MSDP had & GE;25% lower risks of cancer than women with the lowest MSDP (HR (moderate vs. lowest): 0.71, 95% CI: 0.52-0.97 and HR (highest vs. lowest): 0.74; 95% CI: 0.55-0.99). The association between MSDP score and cancer risk in men was weaker except in non-smokers. Beneficial effects of the MSDP in women were stronger among those who were not overweight. In this study, higher adherence to MSDP was associated with lower cancer risk, especially among women.

(-)-Oleocanthal Prevents Breast Cancer Locoregional Recurrence After Primary Tumor Surgical Excision and Neoadjuvant Targeted Therapy in Orthotopic Nude Mouse Models

CANCERS English Article
breast cancer; extra-virgin olive oil; HER2; lapatinib; MET; neoadjuvant; oleocanthal; surgical excision; recurrence VIRGIN OLIVE OIL; IN-VITRO; MEDITERRANEAN DIET; MET EXPRESSION; OLEOCANTHAL; RECEPTOR; GROWTH; METASTASIS; BIOMARKERS; PATTERNS Breast cancer (BC) recurrence represents a challenge for survivors who have had their primary tumors surgically excised, and/or have completed radiation, neoadjuvant, or adjuvant therapeutic regimens. Current BC treatments mostly lack the ability to reduce the risk of disease recurrence. About 70% of BC patients will subsequently suffer disease relapse, manifesting as local, regional, or distant tumor recurrence, which clearly underscores the urgent need to discover novel recurrence inhibitors. (-)-Oleocanthal (OC) is a natural phenolic, found so far exclusively in extra-virgin olive oil (EVOO). OC exerts documented bioactivities against diverse cancer types, inflammation, and neurodegenerative diseases. Herein we report the novel activity of daily oral treatment with OC (10 mg/kg) in preventing BC locoregional recurrence in a nude mouse xenograft model generated by orthotopic inoculation with BT-474 cells as a luminal type B model. We further report inhibition of tumor recurrence by OC after completion of a lapatinib neoadjuvant regimen. However, in a recurrence model of triple-negative breast cancer (TNBC), OC treatment (10 mg/kg) did not effectively prevent tumor recurrence, but rather, was seen to significantly reduce the growth of recurrent tumors as compared to vehicle control-treated animals. Inhibition of tumor recurrence was associated with significant serum level reductions of the human BC recurrence

marker CA 15-3 at the study end in animals treated with OC. OC treatment upregulated the expression of the epithelial marker E-cadherin and downregulated the levels of the mesenchymal marker vimentin in recurrent tumors vs. untreated control animals. OC treatment also reduced the activation of MET and HER2 receptors, as indicated by reduced phosphorylation levels of these proteins in recurrent tumors vs. controls. Collectively, the results of our studies provide the first evidence for suppression of BC tumor recurrence by oral OC treatment in an animal model for such recurrence, and furthermore, highlight favorable prospects for this natural product to emerge as a first-in-class BC recurrence inhibitor. Cytotoxic activity of liposomal Thymus capitatus essential oil on HT-29 human colorectal cancer cell line PHARMAZIE English Article

ANTIOXIDANTMultidrug resistance, severe side effects, and high cancer treatment costs are still well-known issues and remain an open challenge. These factors reduce the therapy's efficiency and safety, seriously affecting human health. Developing therapeutic approaches based on plant extracts, especially based on essential oils with cytotoxic and antioxidant properties, could be of efficacious strategies. This

work incorporated Thymus capitatus essential oil (TEO) in liposomes. Thymus capitatus is a plant native to the northern region of Albania and found specifically in the Mediterranean region. TEO has several biological activities and cytotoxic properties. Due to its volatility, poor solubility, and chemical instability, however, its applicability is restricted. Incorporation into liposomes enables its effective use because the exposure time to the active compounds can be extended, increasing its efficacy against colorectal cancer cell lines, as highlighted in in vitro studies. TEO demonstrated detectable cytotoxic action against HT -29 colorectal cancer cells, and this action could be enhanced by applying various formulations of TEO-loaded liposomes to this cell line. Among the tested nanosystems, TEO-Phospholipon 90H liposomes showed more significant cytotoxic effects than TEO-Lipoid S100 liposomes and TEO-Phospholipon 85G liposomes. TEO-Phospholipon 90 H liposomes also maintained its physicochemical stability for six months at 25 degrees C. This research suggests that TEO, particularly when encapsulated in TEO-Phospholipon 90 H liposomes, may offer a promising therapeutic approach. However, these findings are based on in vitro studies and further in vivo research is needed to validate the efficacy and safety of this approach in clinical settings. Heterogeneity in disease free survival between centers:
lessons learned from an EORTC breast cancer trial CLINICAL TRIALS
English Article

EUROPEAN ORGANIZATION; PERIOPERATIVE CHEMOTHERAPY;
 FRAILTY Background: Large phase III clinical trials convey a lot of important information besides the main analysis of the treatment effect. For example, the use of multicenter clinical trial data to identify prognostic indices is now common. In addition, the study of heterogeneity in patient outcome between centers has received considerable attention in recent years. In this paper, we explain and illustrate a method used to investigate such heterogeneity with data from an early breast cancer clinical trial. Methods: The inclusion of a random effect for center in a Cox proportional hazards model allows us to study the heterogeneity in time-to-event outcomes between centers. Such a model has the major advantage that it provides a measure of the spread of outcomes over centers. This technique is illustrated using data from EORTC trial 10854, a randomized phase III trial comparing perioperative chemotherapy with no perioperative chemotherapy for early breast cancer; 2793 patients were entered by 14 centers. Results: Substantial heterogeneity between centers was detected for disease-free survival. This can be explained by the geographical area in which the center is located, with better outcomes achieved in France as compared with southern Europe and South Africa. None of the prognostic factors considered could explain this heterogeneity. Conclusion: Although clinical trials are run with the objective of removing as much heterogeneity as possible, some heterogeneity in the outcome of patients between centers may remain, as was the case in our study. The use of a random effect for center within a Cox PH model is an excellent method to investigate this heterogeneity. Such types of analyses, although exploratory, provide further insight into possible factors which may have an impact on the patient's outcome.

GENERALIZED MODEL OF INTERNATIONAL MIGRATION DETERMINANTS.

APPLICATION TO EUROPEAN IMMIGRATION FROM SOUTHERN MEDITERRANEAN

COUNTRIES REVUE ECONOMIQUE French Article

POLITICAL-ECONOMY; TRADE;
 RETURNS; SKILL Based on new developments in migration theory,
 this paper develops a model which includes both traditional and
 new migration determinants. An empirical application is
 implemented for European immigration from Southern Mediterranean
 Countries (SMCS). Results show that migrations are not only
 explained by differences in income levels. They also depend on a
 set of many other variables, such as income inequality,
 differences in unemployment and costs of living, the education
 level of the migrants, human networks, differences in languages,
 border effects, migration policy as well as non economic
 determinants, including climate, environment as well as religion.

Concordance with the World Cancer Research Fund/American
 Institute for Cancer Research recommendations for cancer
 prevention and colorectal cancer risk in Morocco: A large,
 population-based case-control study INTERNATIONAL JOURNAL OF
 CANCER English Article

WCRF; AICR recommendations; colorectal cancer; case-
 control study; FFQ; Morocco PHYSICAL-ACTIVITY; NUTRITION
 TRANSITION; RESEARCH GUIDELINES; MEDITERRANEAN DIET; ADHERENCE;
 MORTALITY; PATTERNS; OBESITYThe present study aimed to investigate
 associations between adherence to the recommendations on cancer
 prevention from the WCRF/AICR and colorectal cancer (CRC) risk in
 Morocco. Incident CRC cases (n = 1,516) and controls (n = 1,516)
 matched on age, sex and center, were recruited between September
 2009 and February 2017 at five major hospitals located in Morocco.
 In-person interviews were conducted to assess habitual diet using
 a validated Food Frequency Questionnaire, physical activity and
 anthropometric measurements. Adherence to the WCRF/AICR
 Recommendations was ranged from 0 (no adherence) to 6 (maximal
 adherence) and incorporating six WCRF/AICR components (food
 groups, physical activity and BMI). Multivariable odd ratios (ORA)
 and 95% confidence intervals (CI) were calculated using
 conditional multivariate logistic regression models, with low
 adherence as referent, adjusting for potential confounding
 factors. Compared to those with the lowest adherence score,
 individuals in the highest WCRF/AICR score category had a

statistically significant reduced risk for colon cancer (ORA = 0.63, 95% CI 0.53-0.76); rectal cancer (ORA = 0.52, 95% CI 0.43-0.63) and CRC overall (ORA = 0.58, 95% CI 0.51-0.66). For individual score components, when comparing the lowest with the highest adherence category, CRC risk was significantly lower in the highest adherence category for body fatness (ORA = 0.73; 95% CI 0.62-0.85), physical activity (ORA = 0.70; 95% CI 0.60-0.82), plant foods (ORA = 0.50; 95% CI 0.39-0.63) and red/processed meat (ORA = 0.81; 95% CI 0.71-0.92). Our analysis indicated that greater adherence to the WCRF/AICR recommendations for cancer prevention may lower CRC risk in Morocco. J Gil, A; Ortega, RM; Maldonado, J Gil,
Angel; Ortega, Rosa M.; Maldonado, Jose Wholegrain
cereals and bread: a duet of the Mediterranean diet for the
prevention of chronic diseases PUBLIC HEALTH NUTRITION
English Article

Bread; Cereals; Chronic disease; Grains; Diet; Mediterranean
CORONARY-HEART-DISEASE; GRAIN FOOD-INTAKE; GLYCEMIC LOAD;
CARDIOVASCULAR-DISEASE; RISK-FACTORS; POSTMENOPAUSAL WOMEN;
DIABETES-MELLITUS; COLORECTAL-CANCER; FIBER INTAKE; FINNISH MEN

Objective: The promotion of healthy lifestyles is one of the
major goals of governments and international agencies all over the
world. Wholegrain cereals are rich in nutrients and many
phytochemical compounds, with recognised benefits for health,
including dietary fibre, a number of phenolic compounds, lignans,
vitamins and minerals and other bioactive components. The aim of
the present work is to review the fundamental studies that support
the consumption of wholegrain cereals and bread to prevent chronic
diseases. Design: Descriptive review considering human studies.
Setting and subjects: Subjects included in randomised intervention
trials and cohort studies from different countries published up to
2010. Results: Several studies show consistently that subjects who
ingest three or more portions of foods per day based on wholegrain
cereals have a 20-30% lower risk of CVD than subjects who ingest
low quantities of cereals. This level of protection is not
observed with the ingestion of refined cereals, these being even
higher than with the intake of fruit and vegetables. Likewise,
high intake of wholegrain cereals and their products, such as
whole-wheat bread, is associated with a 20-30% reduction in the
risk of type 2 diabetes. Finally, protection against the risk of
colorectal cancer and polyps, other cancers of the digestive
tract, cancers related to hormones and pancreatic cancer has been
associated with the regular consumption of wholegrain cereals and
derived products. Conclusions: The regular intake of wholegrain
cereals can contribute to reduction of risk factors related to
non-communicable chronic diseases. [Gil, Angel] Univ Granada,

J Calahorra, J; Martínez-Lara, E; De Dios, C; Siles, E
 Calahorra, Jesus; Martinez-Lara, Esther; De Dios, Cristina; Siles, Eva Hypoxia modulates the
 antioxidant effect of hydroxytyrosol in MCF-7 breast cancer cells
 PLOS ONE English Article

OLIVE OIL PHENOLICS; OXIDATIVE STRESS;
 THERAPEUTIC TARGET; HEME OXYGENASE-1; RISK; INVOLVEMENT;
 INDUCTION; PATHWAYS; PROTECTS; MUSCLE Although cancer is
 multifactorial, a strong correlation between this pathology and
 increased oxidative stress has long been established. Hypoxia,
 inherent to solid tumors, increases reactive oxygen species and
 should be taken into account when analyzing the response of tumor
 cells to antioxidants. The Mediterranean diet has been related to
 a lower incidence of cancer, and particularly of breast cancer.
 Given that hydroxytyrosol (HT) is largely responsible for the
 antioxidant properties of olive oil, we have performed a
 comprehensive and comparative study of its effect on the oxidative
 stress response of the human breast cancer cell line MCF-7 in
 hypoxia and normoxia. Our results demonstrate that the antioxidant
 action of HT is particularly effective in a hypoxic environment.
 Moreover, we have observed that this polyphenol modulates the
 transcription and translation of members of the PGC-1 alpha/ERR
 alpha and PGC-1 alpha/Nrf2 pathways. However, while the
 transcriptional effects of HT are similar in normoxic and hypoxic
 conditions, its translational action is less prominent and
 partially attenuated in hypoxia, and therefore cannot completely
 explain the antioxidant effect of HT. Consequently, our results
 underscore that the hypoxic environment of tumor cells should be
 considered when analyzing the effect of bioactive compounds.
 Besides, this study also points to the importance of assessing the
 regulatory role of HT at both mRNA and protein level to get a
 complete picture of its effects. [Calahorra, Jesus; Martinez-

GAMMA-LINOLENIC ACID; ESTROGEN-RECEPTOR EXPRESSION;
MONOUNSATURATED FATTY-ACID; ACTIVATED PROTEIN-KINASE; CELL-CYCLE
ARREST; BREAST-CANCER; OLEIC-ACID; PHENOLIC-COMPOUNDS; COLORECTAL-
CANCER; LUNG-CANCER Virgin olive oil is a characteristic
component and the main source of fat of the Mediterranean diet. It
is a mix of high-value health compounds, including monounsaturated
fatty acids (mainly oleic acid), simple phenols (such as
hydroxytyrosol and tyrosol), secoiridoids (such as oleuropein,
oleocanthal), flavonoids, and terpenoids (such as squalene). Olive
oil consumption has been shown to improve different aspects of
human health and has been associated with a lower risk of cancer.
However, the underlying cellular mechanisms involved in such
effects are still poorly defined, but seem to be related to a
promotion of apoptosis, modulation of epigenetic patterns,
blockade of cell cycle, and angiogenesis regulation. The aim of
this review is to update the current associations of cancer risk
with the Mediterranean diet, olive oil consumption and its main
components. In addition, the identification of key olive oil
components involved in anticarcinogenic mechanisms and pathways
according to experimental models is also addressed. [Farras,

Prevalence of high risk human papillomavirus types 16/18 in
cytologically abnormal cervical smears in Alexandria, Egypt. A
cytological molecular study MIDDLE EAST FERTILITY SOCIETY JOURNAL
English Article

Human papillomavirus; Polymerase chain reaction; High-risk
human papilloma-virus 16 and 18; Cervical cancer; Cervical smear

Introduction: In Egypt, cervical cancer ranks as the second most frequent cancer after breast cancer, among women between 15 and 44 years of age. High-risk human papillomavirus (HPV) 16 and 18 detection holds the potential to be used as a tool to detect women, at risk for consequent development of cervical cancer because of their predominance and potentially greater oncogenic nature than other high risk HPV subtypes. Objective: To determine the prevalence of high-risk HPV 16/18 DNA in women with abnormal cervical cytology. Subjects and methods: 45 cases were collected from Egyptian women seeking routine gynecologic care. Ten cytologically normal cervical smear cell samples were included in the study as a control to be tested for the presence of HPV 16/18 DNA and were collected from asymptomatic patients having cystoectocoele or coming for loop insertion or removal. The 45 specimens were subjected to real-time polymerase chain reaction, using multiplex HPV 16 and 18 PCR kit. Results: 45 cervical smears were collected in the present study. Cytopathological examination revealed that 5 (11.1%) were ASCUS, 8 (17.8) were LSIL, 5 (11.1%) were HSIL, 1 (2.2%) was squamous cell carcinoma (SCC), 1 (2.2%) was adenocarcinoma and 25 (55.6%) were benign (inflammatory). 20 patients with abnormal cervical cytology and 10 controls were included in the present study. In patients with abnormal cervical cytology, 5 (25%) were ASCUS, 8 (40%) were LSIL, 5 (25%) were HSIL, and 1 (5%) was SCC and 1 (5%) was adenocarcinoma. Statistical analysis revealed a significant difference between patient and control groups as regards regularity of menstruation where irregular menstruation and higher prevalence of menopausal women, abnormal vaginal bleeding, menorrhagia, vaginal infection, and abnormal cervical appearance were encountered in patients. A statistically significant higher prevalence of married women was found in the control group. There was no significant difference in the distribution of patients and control as regards HPV 16 or HPV 18 in which 20% of patients were HPV 16 positive and 10% of patients were HPV 18 positive compared with none in the control group. 6 were positive either for HPV 16 or 18, while 39 were negative. The HPV 16/18 positive patients had significantly higher age and marital duration when compared with HPV 16/18 negative group. Significantly, most of the HPV 16/18 positive patients were menopause. A significantly higher prevalence of women with cervicitis, contraceptive users and married women was in the HPV 16/18 negative group. Conclusion: The study generates epidemiological data of prevalence of HPV 16/18 in cytologically abnormal cervical smears in women seeking routine gynecologic care at the outpatient clinics of the Obstetrics and Gynecology Department at El Shatby University. High-risk HPV DNA testing by PCR of cervical samples diagnosed according to the Bethesda 2001

guidelines may benefit the management of patients with abnormal cervical smears, especially among women aged 46 years and older, in menopausal women and in women complaining of PMB. Therefore, HPV DNA testing should be made use of as an adjunct to cervical smears. (C) 2013 Production and hosting by Elsevier B.V. on behalf of Middle East Fertility Society. J Acheampong, AO; Opoku, EEO Acheampong, Alex O.; Opoku, Eric Evans Osei Democracy, Human Capital, and Foreign Direct Investment: Evidence From Developing Economies ECONOMICS & POLITICS English Article; Early Access democracy; developing economies; foreign direct investment; human capital; location theory; multinational companies DEVELOPING-COUNTRIES; NATURAL-RESOURCES; INSTITUTIONS; INFLOWS; GROWTH; FDI; DETERMINANTS; GOVERNANCE; REVERSAL; ORIGINS This paper examines the role of human capital in democracy and foreign direct investment (FDI) relationship in 129 developing countries from 1980 to 2022. Democracy is viewed as a multidimensional concept with five measures: electoral, liberal, egalitarian, participatory, and participation democracy. Employing the dynamic generalized method of moments, the findings demonstrate that democracy indices and human capital have direct, positive, and significant impact on FDI. Additionally, we observe that democracy indices increase FDI inflows when the human capital index is above a certain threshold, while democracy variables decrease FDI inflows below this threshold. The paper also reveals that democracy reduces FDI inflows to low-income economies, sub-Saharan Africa, and Middle East and North Africa countries. However, it increases FDI inflows to middle-income economies and other developing regions. These findings are robust to alternative econometric techniques and model specifications. The findings underscore the importance of enhancing democratization and human capital development to attract FDI to developing economies. radioresistance in drug resistant human MCF-7 breast cancer cells
JOURNAL OF RADIOTHERAPY IN PRACTICE English
Article MDR1; MCF-7;
radioresistance; Real-time PCR Background and purpose:
Radiotherapy is used for the treatment of malignant tumours, and
may be used as the primary therapy. It is also common to combine
radiotherapy with surgery, chemotherapy, hormone therapy or some
combination of them. Even if the tumour is treated intensively,
women diagnosed with breast cancer may develop a recurrence. Most
recurrences may be in the form of distant metastases, development
of multi-drug resistance phenotype or both together. This study
demonstrated that some of the multi-drug resistant cancer cells
may also become radioresistant. Materials and Methods:
Chemoresistance in paclitaxel (MCF-7/Pac), docetaxel (MCF-7/Doc),
vincristine (MCF-7/Vinc), doxorubicin (MCF-7/Dox) and zoledronic
acid (MCF-7/Zol) resistant MCF-7 cells were demonstrated by XTT
assay. MDR1 gene expression was detected by real-time PCR in human
MCF-7 breast cancer cells. Drug resistant and sensitive cells were
exposed to g-radiation and development of radioresistance was
investigated. Results: Results have indicated that paclitaxel,
docetaxel, vincristine, doxorubicin and zoledronic acid-selected
cells gained varying degrees of resistance to their selective
drugs when compared with original MCF-7/S. MCF-7/Pac, MCF-7/Doc,
MCF-7/Vinc and MCF-7/Dox cells have all acquired MDR1 expression.
Among the resistant sub-lines, MCF-7/Pac and MCF-7/Doc cells were
significantly cross-resistant to irradiation compared to the
sensitive cells. Conclusion: MCF-7/Pac and MCF-7/Doc cell lines
were found radioresistant to g-radiation. On the contrary,
doxorubicin, vincristine and zoledronic acid resistant cancer
cells were still sensitive to radiation. [Kars, Meltem

 Atmaca, Harika; Ilhan, Suleyman; Yilmaz, Elif Serel; Zora,
 Metin 4-Propargyl-substituted 1H-pyrroles induce
 apoptosis and autophagy via extracellular signal-regulated
 signaling pathway in breast cancer ARCHIV DER PHARMAZIE
 English Article
 apoptosis; autophagy; cytotoxicity; ERK1; 2; pyrrole
 derivatives BIOLOGICAL-ACTIVITY; CELL-DEATH; PYRROLE; DERIVATIVES;
 MECHANISMS; ERK Novel pyrrole derivatives (PDs) with propargyl
 units (1-7) were investigated for their anticancer activity on
 breast cancer cells. The MTT assay was used to assess the cell
 viability. Morphological changes in human breast cancer cells were
 visualized under a phase-contrast microscope. Apoptosis and
 autophagy were detected using the DNA fragmentation assay and
 staining by autophagic vacuoles, respectively. The levels of
 apoptosis- and autophagy-related proteins such as cytochrome c,
 Bcl-2, LC3-I/II were investigated by Western blot analysis. The
 effect of PDs on the ERK1/2 signaling pathway was investigated
 using specific inhibitors. All the tested PDs were found to be
 active in the range of 36.7 +/- 0.2 to 459.7 +/- 4.2 mu M.
 Compounds 3 and 4 showed cytotoxic activity in breast cancer
 cells, but were found to be safer with lower cytotoxicity on human
 nontumorigenic epithelial breast cells. Compound 4 induced
 apoptosis, whereas compound 3 induced autophagy. Both compounds
 inhibited the ERK signaling pathway in breast cancer cells. The
 present study revealed that both synthesized PDs induced different
 programmed cell death types by inhibiting the ERK signaling
 pathway in two genotypically different breast cancer cells.
 Therefore, novel PDs might be promising anticancer agents for
 breast cancer therapy and further structural modifications of PDs
 may yield promising anticancer agents. [Atmaca, Harika; Ilhan,

Evaluation of Turkish propolis for its chemical
composition, antioxidant capacity, anti-proliferative effect on
several human breast cancer cell lines and proliferative effect on
fibroblasts and mouse mesenchymal stem cell line JOURNAL OF
APICULTURAL RESEARCH English Article

propolis; antioxidant capacity; phenolic
profile; HPLC-PDA; breast cancer cell line; mesenchymal stem cell
line RADICAL-SCAVENGING ACTIVITY; BRAZILIAN RED PROPOLIS; POPLAR-
TYPE PROPOLIS; PHENOLIC-COMPOUNDS; IN-VITRO; CONSTITUENTS;
APOPTOSIS; EXTRACTS; REGIONS; ASSAY Propolis is an extremely
complex resinous natural compound collected by honey bees from
various plant sources and exhibits pharmacological and biological
properties attributed to the presence of polyphenols. This study
examined the total phenolic and flavonoid contents as well as the
total antioxidant capacity using 2,2'-azino-bis(3-
ethylbenzothiazoline-6-sulphonic acid (ABTS), 2,2-diphenyl-1-
picrylhydrazyl (DPPH), cupric-reducing antioxidant capacity
(CUPRAC), and ferric-reducing antioxidant power (FRAP) methods.
Turkish propolis has very high total phenolic (314.36 +/- 3.65 mg
GAE/g propolis) and total flavonoid contents (522.71 +/- 11.45 mg
QE/g propolis). The highest antioxidant capacity value was
obtained by the CUPRAC method (1184.94 +/- 63.27 mg TE/g
propolis). Phenolic profile of Turkish propolis was also
determined by high performance liquid chromatography with
photodiode array detection (HPLC-PDA) method. The main phenolic
compounds identified in Turkish propolis was flavonoids including
pinocembrin > chrysin > galangin > pinobanksin > pinostrobin and
phenolic acids including caffeic acid > p-coumaric acid > ferrulic
acid > t-cinnamic acid. In the present work, anti-proliferative
and proliferative effects of propolis extracts were also
investigated on two different breast cancer cell lines; MDA-MB-
231, UACC-3199 and on two normal cell lines; fibroblasts and mouse
mesenchymal stem cell lines. According to the XTT results, Turkish
propolis sample showed significant anti-proliferative effect on
MDA-MB-231 and UACC breast cancer cell lines. Interestingly,
Turkish propolis sample had proliferative effect on both
fibroblasts and mouse mesenchymal stem cells. These results
suggest that Turkish propolis can be considered as a potent agent
on breast cancer treatment for further investigations. [Ozdal,

Cost-benefit analysis of a projected national
human papilloma virus vaccination programme in Lebanon EASTERN
MEDITERRANEAN HEALTH JOURNAL English Article

HPV vaccination; cost benefit
analysis; cervical cancer; Lebanon EXTENDED MIDDLE-EAST;
CERVICAL-CANCER; HPV VACCINE; IMPACT; QUADRIVALENT; PREVENTION;
INFECTION; EFFICACY; BIVALENT; HEALTH Background: The adoption
of a population-based human papilloma virus (HPV) vaccination
programme is debated in Lebanon on epidemiological, sociocultural,
logistical and economic grounds. Aims: This cost-benefit analysis
contributes to generating quantitative evidence necessary for a
decision regarding costs through locally available data. Methods:
The 2 sides of the cost-benefit analysis equation are: estimation
of the cost of HPV vaccination campaigns targeting 11 year-old
girls, using the cheapest vaccine in 2016 and estimation of the
management cost for treatment of a yearly average case-load for
cervical cancer. Results: A Cervarix (R) only campaign would cost
US\$ 5 407 790 to vaccinate 38 08311-year-old girls. The estimated
cost of managing a mean annual mixed case-load of 100 incident
cervical cancer cases would cost US\$ 1 591 336. The nearest break-
even point may occur 5 years after this current analysis.
Conclusion: This cost-benefit analysis using limited available
data indicates that massive HPV vaccination would not be cost-
beneficial under the circumstances existing in 2016. Nevertheless,
some indications point to the need for a re-assessment around
2020. This finding will inform public health decision-makers in
Lebanon and similar neighbouring countries. [Bahr, Sarah; Bzieh,

 Perez-Jimenez, Jara; Elena Diaz-Rubio, M.; Saura-
 Calixto, Fulgencio Contribution of Macromolecular
 Antioxidants to Dietary Antioxidant Capacity: A Study in the
 Spanish Mediterranean Diet PLANT FOODS FOR HUMAN NUTRITION
 English Article

Dietary antioxidants; Dietary antioxidant capacity; Food
 antioxidant capacity; Macromolecular antioxidants; Non-extractable
 polyphenols; Spanish Mediterranean diet NONEXTRACTABLE
 POLYPHENOLS; CARDIOVASCULAR-DISEASE; MOLECULAR-MECHANISMS; PLANT
 FOODS; FIBER; CANCER; FRUITS; ASSAY; MICE Epidemiological and
 clinical studies show that diets with a high antioxidant capacity,
 such as those rich in plant food and beverages, are associated
 with significant decreases in the overall risk of cardiovascular
 disease or colorectal cancer. Current studies on dietary
 antioxidants and dietary antioxidant capacity focus exclusively on
 low molecular weight or soluble antioxidants (vitamins C and E,
 phenolic compounds and carotenoids), ignoring macromolecular
 antioxidants. These are polymeric phenolic compounds or
 polyphenols and carotenoids linked to plant food macromolecules
 that yield bioavailable metabolites by the action of the
 microbiota with significant effects either local and/or systemic
 after absorption. This study determined the antioxidant capacity
 of the Spanish Mediterranean diet including for the first time
 both soluble and macromolecular antioxidants. Antioxidant capacity
 and consumption data of the 54 most consumed plant foods and
 beverages were used. Results showed that macromolecular
 antioxidants are the major dietary antioxidants, contributing a 61
 % to the diet antioxidant capacity (8000 μmol Trolox, determined
 by ABTS method). The antioxidant capacity data for foods and
 beverages provided here may be used to estimate the dietary
 antioxidant capacity in different populations, where similar
 contributions of macromolecular antioxidants may be expected, and
 also to design antioxidant-rich diets. Including macromolecular
 antioxidants in mechanistic, intervention and observational
 studies on dietary antioxidants may contribute to a better
 understanding of the role of antioxidants in nutrition and health.

Chemotherapy; Ionizing radiation KETOGENIC MEDITERRANEAN DIET;
KETONE-BODIES; BODY-COMPOSITION; MONOCARBOXYLATE TRANSPORTERS;
ADJUVANT CHEMOTHERAPY; TUMOR METABOLISM; LACTATE INCREASE;
GLYCEMIC INDEX; VITAMIN-D; GROWTH Background: Ketogenic diets
(KDs) or short-term fasting are popular trends amongst supportive
approaches for cancer patients. Beta-hydroxybutyrate (3-OHB) is
the main physiological ketone body, whose concentration can reach
plasma levels of 2-6 mM during KDs or fasting. The impact of 3-OHB
on the biology of tumor cells described so far is contradictory.
Therefore, we investigated the effect of a physiological
concentration of 3 mM 3-OHB on metabolism, proliferation, and
viability of breast cancer (BC) cells in vitro. Methods: Seven
different human BC cell lines (BT20, BT474, HBL100, MCF-7, MDA-MB
231, MDA-MB 468, and T47D) were cultured in medium with 5 mM
glucose in the presence of 3 mM 3-OHB at mild hypoxia (5% oxygen)
or normoxia (21% oxygen). Metabolic profiling was performed by
quantification of the turnover of glucose, lactate, and 3-OHB and
by Seahorse metabolic flux analysis. Expression of key enzymes of
ketolysis as well as the main monocarboxylic acid transporter MCT2
and the glucose-transporter GLUT1 was analyzed by RT-qPCR and
Western blotting. The effect of 3-OHB on short- and long-term cell
proliferation as well as chemo- and radiosensitivity were also
analyzed. Results: 3-OHB significantly changed the oxygen
consumption rate (OCR) and extracellular acidification rate (ECAR)
in BT20 cells resulting in a more oxidative energetic phenotype.
MCF-7 and MDA-MB 468 cells had increased ECAR only in response to
3-OHB, while the other three cell types remained uninfluenced. All
cells expressed MCT2 and GLUT1, thus being able to uptake the
metabolites. The consumption of 3-OHB was not strongly linked to
mRNA overexpression of key enzymes of ketolysis and did not
correlate with lactate production and glucose consumption. Neither
3-OHB nor acetoacetate did interfere with proliferation. Further,
3-OHB incubation did not modify the response of the tested BC cell
lines to chemotherapy or radiation. Conclusions: We found that a
physiological level of 3-OHB can change the energetic profile of
some BC cell lines. However, 3-OHB failed to influence different
biologic processes in these cells, e.g., cell proliferation and
the response to common breast cancer chemotherapy and
radiotherapy. Thus, we have no evidence that 3-OHB generally
influences the biology of breast cancer cells in vitro.

papillomavirus genital infection in southern Iranian women:
population-based study versus clinic-based data VIROLOGY
JOURNAL English Article

Human papilloma virus; Bushehr; Cervical cancer; Iran;
PCR CERVICAL-CANCER; HPV TYPES; PREVALENCE; CYTOLOGY; WORLDWIDE;
SMEAR Background: Epidemiological studies on genital human
papilloma viruses infection (HPVs) in general population are
crucial for the implementation of health policy guidelines for
developing the strategies to prevent the primary and secondary
cervical cancer. In different parts of Iran, there is a lack of
population-based studies to determine the prevalence of HPV in the
general population. The aim of this population-based study is to
compare the prevalence rate of genital HPV infection among
reproductive women with our previous clinic-based data, which
showed a prevalence rate of 5% in women in southern Iran. Results:
Using general primers for all genotypes of HPV, of 799 randomly
selected women, five (0.63%, 95% CI 0.23-1.55%) tested positive
for HPV DNA. Overall, seven different HPV genotypes were detected:
six types (16, 18, 31, 33, 51 and 56) were carcinogenic, or "high
risk genotypes" and one genotype (HPV-66) was "probably
carcinogenic." Conclusions: In a population-based study, the
prevalence of HPV infection among southern Iranian women was lower
than that observed worldwide. However, our gynaecological clinic-

based study on the prevalence of HPV infection showed results comparable with other studies in the Middle East and Persian Gulf countries. Since gynaecological clinic-based data may generally overestimate HPV prevalence, estimates of prevalence according to clinic-based data should be adjusted downward by the population-based survey estimates. J Pourianazar, NT; Gunduz, U Pourianazar,
Negar Taghavi; Gunduz, Ufuk Changes in apoptosis-
related gene expression and cytokine release in breast cancer
cells treated with CpG-loaded magnetic PAMAM nanoparticles
INTERNATIONAL JOURNAL OF PHARMACEUTICS English
Article CpG-ODN; Apoptosis-
related genes; Cytokine release; Dendrimeric nanoparticles;
Magnetic nanoparticles TOLL-LIKE RECEPTORS; CELLULAR INVASION;
OVARIAN-CANCER; BCL-2 FAMILY; SURVIVIN; PROLIFERATION;
INTERLEUKIN-6; DELIVERY; BAX; OLIGODEOXYNUCLEOTIDES CpG-
oligodeoxynucleotide (CpG-ODN) can function as an immune adjuvant.
Previously, we showed that stimulation of breast cancer cells with
CpG-ODN conjugated with PAMAM dendrimer-coated magnetic
nanoparticles (DcMNP) has induced apoptosis. The aim of the
current study was to evaluate the expression levels of some
apoptosis-regulating genes in several human breast cancer cells
treated with CpG/DcMNP. Treated MDA-MB231 cells showed an
increase in Noxa and Bax gene expression levels, whereas the
expression level of Survivin decreased. Similarly, Noxa gene was
overexpressed in treated MCF7 cells. In treated SKBR3 cells, a
decline in the c-Flip mRNA level was determined. Furthermore,

release of cytokines, IL-6, IL-10, and TNF-alpha, was determined in cell culture supernatants. CpG/DcMNP treatment leads to an increase in the release of IL-6 in MDA-MB231 and SKBR3 cells, whereas release of IL-10 and TNF-alpha did not change significantly. It is indicated that CpG-ODN may show its cytotoxic effect by regulating the expression of apoptosis-related genes and the release of cytokine in breast cancer cells. (C) 2016 Elsevier B.V. Extra-virgin olive oil (EVOO - the juice of the olive obtained solely by pressing and consumed without any further refining process) is unique among other vegetable oils because of the high level of naturally occurring phenolic compounds, We explored the ability of EVOO polyphenols to modulate HER2 tyrosine kinase receptor-induced in vitro transformed phenotype in human breast epithelial cells. Using MCF10A normal breast epithelial cells retrovirally engineered to overexpress the wild-type sequence of human HER2, we further determined the relationship between chemical structures of EVOO-

derived phenolics and their inhibitory activities on the tyrosine kinase activity of the HER2 oncoprotein. When the activation (phosphorylation) status of HER2 was semi-quantitatively measured the secoiridoids blocked HER2 signaling by rapidly reducing the activation status of the 1248 tyrosine residue (Y1248), the main autophosphorylation site of HER2. EVOO-derived single phenols tyrosol and hydroxytyrosol and the phenolic acid elenolic acid failed to significantly decrease HER2 tyrosine kinase activity. The anti-HER2 tyrosine kinase activity IC₅₀ values were up to 5-times lower in the presence of EVOO-derived lignans and secoiridoids than in the presence of EVOO-derived single phenols and phenolic acids. EVOO polyphenols induced strong tumoricidal effects by selectively triggering high levels of apoptotic cell death in HER2-positive MCF10A/HER2 cells but not in MCF10A/pBABL matched control cells. EVOO lignans and secoiridoids prevented HER2-induced in vitro transformed phenotype as they inhibited colony formation of MCF10A/HER2 cells in soft-agar. Our current findings not only molecularly support recent epidemiological evidence revealing that EVOO-related anti-breast cancer effects primarily affect the occurrence of breast tumors over-expressing the type I receptor tyrosine kinase HER2 but further suggest that the stereochemistry of EVOO-derived lignans and secoiridoids might provide an excellent and safe platform for the design of new HER2 targeted anti-breast cancer drugs. Esra; Luleci, Guven; Ozcelik, Tayfun; Colak, Taner; Schayek, Hagit; Akaydin, Mustafa; Friedman, Eitan Germline Mutations in the BRCA1 and BRCA2 Genes in Turkish Breast/Ovarian Cancer Patients HUMAN MUTATION English Article

BRCA1; BRCA2; DGGE; PTT; Turkish Population; high risk for breast cancer In this study we genotyped Turkish breast/ovarian cancer patients for BRCA1/BRCA2 mutations: protein truncation test (PTT) for exon 11 BRCA1 of and, multiplex PCR and denaturing gradient gel electrophoresis (DGGE) for BRCA2, complemented by DNA sequencing. In addition, a modified restriction assay was used for analysis of the predominant Jewish mutations: 185delAG, 5382InsC, Tyr978X (BRCA1) and 6174delT (BRCA2). Eighty three breast/ovarian cancer patients were screened: twenty three had a positive family history of breast/ovarian cancer, ten were males with breast cancer at any age, in eighteen the disease was diagnosed under 40 years of age, one patient had ovarian cancer in addition to breast cancer and one patient had ovarian cancer. All the rest (n=30) were considered sporadic breast cancer cases. Overall, 3 pathogenic mutations (3/53-5.7%) were detected, all in high risk individuals (3/23 - 13%): a novel (2990insA) and a previously described mutation (R1203X) in BRCA1, and a novel mutation (9255delT) in BRCA2. In addition, three missense mutations [two novel (T42S, N2742S) and a previously published one (S384F)] and two neutral polymorphisms (P9P, P2532P) were detected in BRCA2. Notably none of the male breast cancer patients harbored any mutation, and none of the tested individuals carried any of the Jewish mutations. Our findings suggest that there are no predominant mutations within exon 11 of the BRCA1 and in BRCA2 gene in Turkish high risk families. (c) 2003 Wiley-Liss, Inc. [Manguoglu, A. J Oddo, VM; Mabli, J Oddo, Vanessa M.; Mabli, James Association of Participation in the Supplemental Nutrition Assistance Program and Psychological Distress AMERICAN JOURNAL OF PUBLIC HEALTH English Article SEASONAL

AFFECTIVE-DISORDER; SERIOUS MENTAL-ILLNESS; MEDITERRANEAN DIETARY PATTERN; POISSON REGRESSION APPROACH; FOOD INSECURITY; DEPRESSIVE SYMPTOMS; WELFARE RECIPIENTS; GENERAL-POPULATION; FINANCIAL STRAIN; UNITED-STATES Objectives. We assessed whether households' participation in the Supplemental Nutrition Assistance Program (SNAP) was associated with improvements in well-being, as indicated by lower rates of psychological distress. Methods. We used longitudinal data for 3146 households in 30 states, collected between October 2011 and September 2012 for the SNAP Food Security survey, the largest longitudinal national survey of SNAP participants to date. Analyses compared households within days of program entry to the same households approximately 6 months later. We measured psychological distress in the past 30 days on a 6-item Kessler screening scale and used multivariable regression to estimate associations between SNAP participation and psychological distress. Results. A smaller percentage of household heads exhibited psychological distress after 6 months of participation in SNAP than at baseline (15.3% vs 23.2%; difference=-7.9%). In adjusted models, SNAP participation was associated with a decrease in psychological distress (adjusted relative risk = 0.72; 95% confidence interval=0.66, 0.78). Conclusions. Continuing support for federal nutrition programs, such as SNAP, may reduce the public health burden of mental illness, thus improving well-being among vulnerable populations. Prevalence, spectrum, and founder effect of BRCA1 and BRCA2 mutations in epithelial ovarian cancer from the Middle East HUMAN MUTATION
English Article

BRCA1; BRCA2; epithelial; mutation; ovarian cancer BREAST-CANCER; WOMEN; RISK; CARRIERS; SURGERY; ACCOUNT Germline mutations in breast cancer susceptibility gene 1 and 2 have previously been estimated to contribute to 13-18% of all epithelial ovarian cancer (EOC). To characterize the prevalence and effect of BRCA1 and BRCA2 mutations in Middle Eastern EOC patients, BRCA mutation screening was performed in 407 unselected ovarian cancer patients using targeted capture and/or Sanger sequencing. A total of 19 different pathogenic variants (PVs) were identified in 50 (12.3%) women. Nine PVs were recurrent accounting for 80% of cases with PVs (40/50) in the entire cohort. Founder mutation analysis revealed only two mutations (c.4136_4137delCT and c.1140dupG) sharing the same haplotypes thus representing founder mutations in the Middle Eastern population. Identification of the mutation spectrum, prevalence, and founder effect in Middle Eastern population facilitates genetic counseling, risk assessment, and development of a cost-effective screening strategy. Diet Implemented by Telephone Counseling JOURNAL OF THE
AMERICAN DIETETIC ASSOCIATION English Article

CARDIOVASCULAR RISK;

RANDOMIZED-TRIAL; BODY-WEIGHT; GREEK DIET; OLIVE OIL; CANCER; INTERVENTION; SURVIVAL; FRUIT; CAROTENOIDS A Greek-Mediterranean dietary pattern has two distinct aspects that differ relative to average intakes in the United States: a high intake of monounsaturated fats and a high intake of fruit and vegetables. The purpose of the study was to develop and test an exchange list Greek-Mediterranean diet that could be used in future clinical trials of breast cancer prevention. A total of 69 women, ages 25 to 59 years, were randomized to either continue their own usual diet or follow an intervention diet for 6 months during 2004 through 2005. Intervention goals were to decrease usual fat intakes by about half and to replace those fats with olive oil and other high-monounsaturated fatty acid foods; increase fruit and vegetable intakes to 7 to 9 servings/day, depending on energy intake; and consume at least one serving per day each of culinary herbs and album vegetables. Registered dietitians provided exchange goals and individualized telephone counseling, and diets were self-selected using a Mediterranean exchange list developed specifically for this study. Changes in diet were assessed by 7-day food records. Results demonstrated that counseling using the Mediterranean exchange list was effective for large dietary changes relative to the nonintervention group. Repeated measures analysis of variance indicated a statistically significant 48% increase in dietary monounsaturated fat with no appreciable change in total fat intake, and a significant increase in fruit and vegetable intake from 4.0 to 8.6 servings/day ($P < 0.05$).

Eribulin mesylate use as third-line therapy in patients with metastatic breast cancer (VESPRY): a prospective, multicentre, observational study THERAPEUTIC ADVANCES IN MEDICAL ONCOLOGY English Article

eribulin; metastatic breast cancer; multicentre; prospective; real world; third line ANTHRACYCLINE; EFFICACY; WOMEN; TAXANE; SITE Background: In real-world practice, eribulin mesylate provides significant survival benefit, with a manageable safety profile in heavily pretreated patients with metastatic breast cancer (MBC). Methods: In this prospective, open-label, multicentre, observational study we evaluated the effectiveness and tolerability of eribulin as third-line treatment in a homogeneous population. The primary endpoints were the safety profile and response in metastatic sites; secondary endpoints included the response in different subtypes, overall response rate (ORR), progression-free survival (PFS) and overall survival (OS). Results: From 2013 to 2016, 118 women were treated in 21 Sicilian institutions; the median age was 58 years (range 29-79), with 69% of patients under 65. The median cycles of eribulin were 5.5 (range 1-26). The most common adverse event was neutropenia (9.3%, 3 cases of grade 3, 4 of grade 4); only 1 case of QT prolongation was reported. Eribulin was effective in controlling metastatic disease in all sites, and it achieved the highest ORR in brain (16%) and liver (14.9%). Median OS was 31.8 months (95% CI 27.9-34.4) and median PFS 5.5 months (95% CI 4.2-6.6). PFS was 5.2 months (95% CI 2.8-8.4) in patients with triple-negative subtype. Median PFS was longer in patients over 65 years (6.1 months, 95% CI 4.4-8.3). In patients who had visceral metastases PFS was 5.5 months (95% CI 3.5-6.6) and OS 33.9 months (95% CI 29.8-40.8). Conclusions: Eribulin as third-line treatment shows an acceptable safety profile and a substantial antitumour activity in the treatment of MBC, even in elderly patients and in those with visceral disease.

Evaluation of CAMD1 Gene Promoter
Hypermethylation in Human Papillomavirus Positive Cytological
Samples of Cervical Cancer MIDDLE EAST JOURNAL OF CANCER
English Article

Human papillomavirus; Uterine cervical neoplasms;
Hypermethylation; Epigenomics METHYLATION; EXPRESSION

Background: Cervical cancer (CC) is the second most common type of cancer among women. A key factor in developing the disease is the human papillomavirus (HPV) infection. Aberrant DNA hypermethylation in gene promoter regions is one of the most well-defined epigenetic alterations in tumors. This study aimed to investigate cell adhesion molecule 1 (CADM1), promoter methylation in HPV serological positive samples in the Iranian population. Method: Genomic DNA was extracted from cervical smears from patients and healthy patients acting as a control group for this analytical observational case-control investigation. Reverse dot blotting was performed to first identify the presence of HPV DNA infection. After that, each sample was transformed by being treated with sodium bisulfite, and MSP was then used to determine the CADM1 gene's level of methylation. Results: Among total number of positive HPV samples (n = 52), 63.5% methylated, 23% hemi-methylated, and 13.5% were unmethylated. On the contrary, in the control group (n=38), 11% methylated, 71% hemi-methylated, and 18% were unmethylated (P < 0.0001). Furthermore, comparing the methylation status among high, low and high/low patients indicated that methylation was (66.66, 24.24, and 9.09%), (25, 66.66, and 8.33%), and (14.28, 57.14%, and 28.57%), respectively (P < 0.0001). Conclusion: The present study confirmed that the

methylation status of CADM1 gene was significantly higher in HPV-positive patients than in patients negative for HPV DNA. Moreover, the CADM1 pattern of the gene was associated with the high-risk subtypes of HPV, not with the low-risk ones. Therefore, CADM1 methylation appeared to be a promising biomarker for future studies.  Antonio Metabolomic approach for a rapid
 identification of natural products with cytotoxic activity against
 human colorectal cancer cells SCIENTIFIC REPORTS

English Article
 INHIBITS TUMOR-GROWTH; COLON-CANCER; ASTRAGALUS-
 MEMBRANACEUS; ACQUIRED-RESISTANCE; SAPONINS; CHEMOTHERAPY;
 CETUXIMAB; L.; DEREPLICATION; METABOLITES The discovery of
 bioactive compounds from natural sources entails an extremely
 lengthy process due to the timescale and complexity of traditional
 methodologies. In our study, we used a rapid NMR based metabolomic
 approach as tool to identify secondary metabolites with anti-
 proliferative activity against a panel of human colorectal cancer
 cell lines with different mutation profiles. For this purpose,
 fourteen Fabaceae species of Mediterranean vegetation were
 investigated using a double screening method: H-1 NMR profiling
 enabled the identification of the main compounds present in the
 mixtures, whilst parallel biological assays allowed the selection
 of two plant extracts based on their strong anti-proliferative
 properties. Using high-resolution 2D NMR spectroscopy, putative
 active constituents were identified in the mixture and isolated by
 performing a bio-guided fractionation of the selected plant
 extracts. As a result, we found two active principles: a
 cycloartane glycoside and protodioscin derivative. Interestingly,
 these metabolites displayed a preferential anti-proliferative
 effect on colon cancer cell lines with an intrinsic resistance to
 anti-EGFR therapies. Our work provides an NMR-based metabolomic
 approach as a powerful and efficient tool to discover natural
 products with anticancer activities circumventing time-consuming
 procedures. [Graziani, Vittoria; Scognamiglio, Monica; Esposito,

J Berc, G Berc, Gordana
 Croatian Experience with the Refugee Crisis on the Balkan
 Route and Possible Implications for Social Work Practice and
 Education JOURNAL OF HUMAN RIGHTS AND SOCIAL WORK

English Article
 Migration; Legislation; Human rights; Social services;
 Psychosocial support; Social work MENTAL-HEALTH The purpose of
 this review article is to describe some aspects of the migration
 crises experience that Croatia as a Member State on the European
 Union external border went through as a transit country on the
 Balkan route 2015-2016. In that period of time, migrant movement
 was the most intensive, when Croatia received more than 600,000
 refugees and migrants who migrated mainly from Syria, Afghanistan,
 Pakistan, and other Middle East countries, escaping from the war
 devastation. The international and national legal frameworks on
 refugees' rights' protection are presented as well as EU funds for
 the refugee crisis and improving migration management. The main
 focus is on elaboration of organized social services and
 psychosocial support in Croatian reception centers. Interplay
 between public and civil sector in providing needed services for
 the different migrants' needs is explained. Since Croatia in 1990s
 experienced a strong war devastation and refugee crisis,
 comparison on similarities and differences basis is described.
 Migrants' reception-recovery process and aspects of the role of
 the social work profession are highlighted, as well as possible
 improvement in social work practice and education based on the

recent migrant crisis experience. [Berc, Gordana] Univ Zagreb, Fac Law, Dept Social Work, Nazorova 51, Zagreb 10000, Croatia

Adipocyte/Tumor cell crosstalk via IGF-1/TXNIP axis promotes malignancy and endocrine resistance in breast cancer CELL COMMUNICATION AND SIGNALING English Article

Breast Cancer; Endocrine resistance; Adipocytes; Tumor microenvironment; Obesity; IGF-1; TXNIP

ESTROGEN-RECEPTOR-ALPHA; THIOREDOXIN-INTERACTING PROTEIN; GROWTH-FACTOR; TAMOXIFEN RESISTANCE; EXPRESSION; TXNIP; METASTASIS; SURVIVAL Background Despite significant improvements in the outcome of Estrogen Receptor (ER) alpha-positive breast cancer (BC) following the use of endocrine therapies, resistance remains a major challenge. Clinical studies proved that obesity, in addition to promote BC progression, is associated with a reduced efficacy to these treatments, but mechanisms remain unclear. Methods We used co-culture systems followed by validation through an 'ex vivo' model of human mammary obese (Ob) adipocytes and obese endocrine-resistant metastatic Patient-Derived Organoids (PDOs). Transcriptomics with MixOmics-MINT and MetaCore Functional Tools along with lentiviral and pharmacological approaches provide insights into mechanisms. Clinical relevance was investigated using public datasets, transcriptome-based (n = 375), and immunohistochemistry-based (n = 65) evaluations. Results In a model of co-culture, we demonstrated that conditioned media (CM) released by 3T3-L1A adipocytes reduced the sensitivity of parental MCF-7 BC cells to the inhibitory effects of Tamoxifen (Tam) on growth, motility and invasion and significantly increased the proliferative, motile and invasive phenotype of Tam-resistant (TR) BC cells. Transcriptomics identified TXNIP (Thioredoxin-interacting protein), a known tumor suppressor gene, as a network central hub, that was significantly down-regulated in CM-treated MCF-7 and TR cells. Accordingly, TXNIP expression was negatively correlated with Body Mass Index (BMI) in BC patients. Lentiviral TXNIP overexpression and pharmacological induction of TXNIP (i.e.

SAHA) or the blockade of insulin-like growth factor-I (IGF-1) signaling, an obesity hallmark able to affect TXNIP expression, reversed CM-mediated effects. TXNIP down-regulation, proliferation and motility in TR cells were exacerbated by CM derived from Ob 3T3-L1A, and combination of an IGF-1 inhibitor and SAHA abrogated Ob-CM activities. Results were also validated in aromatase inhibitor-resistant BC cells. The effectiveness of IGF-1/TXNIP axis inhibition was confirmed using an 'ex vivo' model of human mammary obese adipocytes and PDO models. Finally, retrospective analyses demonstrated that an IGF-1(high)/TXNIPlow signature was correlated with poorer survival in endocrine-treated BC patients. Conclusions In conclusion, our study sheds new light on adipocyte/BC cell crosstalk, underscoring the potential of targeting IGF-1/TXNIP axis to block this harmful connection, especially in the context of obesity. from Middle East - Molecular and tissue microarray analysis of
genomic instability pathwaysSAUDI MEDICAL JOURNAL

English Article

LEVEL MICROSATELLITE INSTABILITY; REVISED BETHESDA
GUIDELINES; MISMATCH REPAIR; LYNCH-SYNDROME; CANCER; EXPRESSION;
FREQUENCY; MUTATION; PROTEIN; HNPCC Objectives: To evaluate
the overall incidence of microsatellite instability (MSI),
hereditary non polyposis colorectal cancer, and tumor supressor
gene (TP53) mutations in Saudi colorectal carcinomas. Methods: We
studied the MSI pathway in Saudi colorectal cancers (CRC) from 179
unselected patients using 2 methods: MSI by polymerase chain
reaction, and immunohistochemistry detection of mutL homologs 1
and mutS homologs 2 proteins. The TP53 mutations were studied by
sequencing exons 5, 6, 7, and 8. Results: Of the 150 colorectal
carcinomas analyzed for MSI, 16% of the tumors showed high level
instability (MSI-H), 19.3% had low-level instability (MSI-L) and
the remaining 64% tumors were stable. Survival of the MSI-H group
was better as compared to the MSI-L or microsatellite stable group
($p=0.0217$). In the MSI-H group, 48% were familial MSI tumors,
which could be attributable to the high incidence of consanguinity
in the Saudi population. The TP53 mutations were found in 24% of
the cases studied. Conclusions: A high proportion of familial MSI
cases and a lower incidence of TP53 mutations are some of the
hallmarks of the Saudi colorectal carcinomas, which need to be
explored further.

habits, such as the consumption of a healthy diet, may prevent up
to 30-50% of breast cancer (BC) cases. Dietary fats are of
specific interest, as research provides strong evidence regarding
the association of dietary fats and BC. However, there is limited
research on the role of different types of fats including
polyunsaturated (PUFA), monounsaturated (MUFA), and saturated
fatty acids (SFA). The objective of this study was to determine
the effects of lifelong exposure to various dietary fats on
mammary tumour development over a 20-week period. Female
heterozygous MMTV-neu (ndl) YD5 mouse models were fed five
maternal diets containing (1) 10% safflower oil (n-6 PUFA,
control), (2) 3% menhaden oil + 7% safflower oil (marine n-3 PUFA,
control), (3) 3% flaxseed + 7% safflower oil (plant-based n-3
PUFA), (4) 10% olive oil (MUFA), or (5) 10% lard (SFA). The
primary measures, tumour latency, volume, and multiplicity
differed by diet treatment in the following general order, n-6
PUFA > plant n-3 PUFA, SFA, MUFA > marine n-3 PUFA. Overall, these
findings show that the quality of the diet plays a significant
role influencing mammary tumour outcomes. [Hillyer, Lyn M.;

FOOD SCIENCE English Article
Soy; Diet; Mediterranean; Soya; Health BREAST-
CANCER; HEALTHY-ADULTS; CONSUMPTION; PROTEIN; FOODS; RISK;
SUPPLEMENTATION; ADOLESCENCE; ISOFLAVONES; DISORDERS Purpose
This study aims to evaluate if soya consumption can compromise or
positively influence the effects of the Mediterranean diet (MD).

Design/methodology/approach A full literature review has been conducted as part of a proposal of a new point of view on the consumption of soya and its derivatives in areas where until a few decades ago this type of food did not exist at all. Findings There does not seem to be any contraindications for soy systematic use, therefore, excluding historical-geographical reasons, soya could be included in an MD without altering the benefits associated with it. Practical implications - Soya is not advised as a typical food in the MD, but promoting its use could probably contribute to increase the variety of the diet and likely consolidates the positive health benefits characteristic of MD. Originality/value To the best of the authors' knowledge, this review is one of the first to evaluate soybean consumption within the MD. Quantification and Classification of Contrast
Enhanced Ultrasound Breast Cancer Data: A Preliminary Study
DIAGNOSTICS English Article
perfusion; models; breast carcinoma; contrast enhanced ultrasonography; prognostic factors; quantitative analysis ULTRASONOGRAPHY; DIFFERENTIATION; DIAGNOSIS; FEATURES; CRITERIA; LESIONS; BENIGN; WOMEN; US This study aimed to investigate which of the two frequently adopted perfusion models better describes the contrast enhanced ultrasound (CEUS) perfusion signal in order to produce meaningful imaging markers with the goal of developing a machine-learning model that can classify perfusion curves as benign or malignant in breast cancer data. Twenty-five patients with high suspicion of breast cancer were analyzed with exponentially modified Gaussian (EMG) and gamma variate functions (GVF). The adjusted R-2 metric was the criterion for assessing model performance. Various classifiers were trained on the quantified perfusion curves in order to classify the curves

as benign or malignant on a voxel basis. Sensitivity, specificity, geometric mean, and AUROC were the validation metrics. The best quantification model was EMG with an adjusted R-2 of 0.60 +/- 0.26 compared to 0.56 +/- 0.25 for GVF. Logistic regression was the classifier with the highest performance (sensitivity, specificity, G(mean), and AUROC = 89.2 +/- 10.7, 70.0 +/- 18.5, 77.1 +/- 8.6, and 91.0 +/- 6.6, respectively). This classification method obtained similar results that are consistent with the current literature. Breast cancer patients can benefit from early detection and characterization prior to biopsy. J Whalen, KA; Judd, S; McCullough, ML; Flanders, WD; Hartman, TJ; Bostick, RM Whalen, Kristine A.; Judd, Suzanne; McCullough, Marjorie L.; Flanders, W. Dana; Hartman, Terryl J.; Bostick, Roberd M. Paleolithic and Mediterranean Diet Pattern Scores Are Inversely Associated with All-Cause and Cause-Specific Mortality in Adults JOURNAL OF NUTRITION English Article

Paleolithic diet; Mediterranean diet; diet patterns; cohort study; mortality CARDIOVASCULAR RISK-FACTORS; CORONARY-HEART-DISEASE; CANCER-RISK; RACIAL-DIFFERENCES; MYOCARDIAL-INFARCTION; COLORECTAL-CANCER; PHYSICAL-ACTIVITY; MEAT CONSUMPTION; NUT CONSUMPTION; BREAST-CANCER Background: Poor diet quality is associated with a higher risk of many chronic diseases that are among the leading causes of death in the United States. It has been hypothesized that evolutionary discordance may account for some of the higher incidence and mortality from these diseases. Objective: We investigated associations of 2 diet pattern scores, the Paleolithic and the Mediterranean, with all-

cause and cause-specific mortality in the REGARDS (REasons for Geographic and Racial Differences in Stroke) study, a longitudinal cohort of black and white men and women ≥ 45 y of age. Methods: Participants completed questionnaires, including a Block food-frequency questionnaire (FFQ), at baseline and were contacted every 6 mo to determine their health status. Of the analytic cohort ($n = 21,423$), a total of 2513 participants died during a median follow-up of 6.25 y. We created diet scores from FFQ responses and assessed their associations with mortality using multivariable Cox proportional hazards regression models adjusting for major risk factors. Results: For those in the highest relative to the lowest quintiles of the Paleolithic and Mediterranean diet scores, the multivariable adjusted HRs for all-cause mortality were, respectively, 0.77 (95% CI: 0.67, 0.89; P-trend < 0.01) and 0.63 (95% CI: 0.54, 0.73; P-trend < 0.01). The corresponding HRs for all-cancer mortality were 0.72 (95% CI: 0.55, 0.95; P-trend = 0.03) and 0.64 (95% CI: 0.48, 0.84; P-trend = 0.01), and for all-cardiovascular disease mortality they were 0.78 (95% CI: 0.61, 1.00; P-trend = 0.06) and HR: 0.68 (95% CI: 0.53, 0.88; P-trend = 0.01). Conclusions: Findings from this biracial prospective study suggest that diets closer to Paleolithic or Mediterranean diet patterns may be inversely associated with all-cause and cause-specific mortality. BRCA2; germline mutations; breast cancer; Cyprus

Germline mutations in the BRCA2 gene have been shown to be associated with familial female and male breast cancer. Mutations occur throughout the entire coding region of the gene, and there is considerable ethnic and geographical diversity in the deleterious mutations detected in different populations. No data exist on the role of the BRCA2 gene in the Cypriot population. In this study we present the results of characterizing mutations in the BRCA2 gene, in 26 Cypriot families with multiple cases of breast / ovarian cancer. The entire coding region, including splice sites, of BRCA2 were sequenced using cycle sequencing. In total 29 BRCA2 variants were detected which include 3 truncating mutations, 8 missense mutations, 6 polymorphisms and 12 intronic variants. The 3 truncating mutations are frameshift mutation 8984delG (exon 22), and two nonsense mutations, namely C1913X (exon 11) which is a novel mutation, and K3326X (exon 27). It is of interest that frameshift mutation 8984delG was the most frequent, since it was detected in 5 patients from three different families. Among the 6 polymorphisms detected, polymorphism T77T is novel and similarly 4 of the 12 intronic variants were also novel, namely IVS1+8G>A, IVS1-96insA, IVS4+36A>G and IVS11-51G>T. These results show that deleterious BRCA2 mutations, occur at the same frequency, about 20%, in Cypriot families, as that recorded in other European populations. We conclude that the BRCA2 gene plays a significant role in the familial breast cancer phenotype in the Cypriot population. (C) 2003 Wiley-Liss, Inc. [Hadjisavvas,

J Hann, M; Sibbald, B; Young, R Hann,
 Mark; Sibbald, Bonnie; Young, Ruth Workforce
 participation among international medical graduates in the
 National Health Service of England: a retrospective longitudinal
 study HUMAN RESOURCES FOR HEALTH English Article
 MIGRATION; PHYSICIANS

Background: Balancing medical workforce supply with demand requires good information about factors affecting retention. Overseas qualified doctors comprise 30% of the National Health Service (NHS) workforce in England yet little is known about the impact of country of qualification on length of stay. We aimed to address this need. Methods: Using NHS annual census data, we calculated the duration of 'episodes of work' for doctors entering the workforce between 1992 and 2003. Survival analysis was used to examine variations in retention by country of qualification. The extent to which differences in retention could be explained by differences in doctors' age, sex and medical specialty was examined by logistic regression. Results: Countries supplying doctors to the NHS could be divided into those with better or worse long-term retention than domestically trained doctors. Countries in the former category were generally located in the Middle East, non-European Economic Area Europe, Northern Africa and Asia, and tended to be poorer with fewer doctors per head of population, but stronger economic growth. A doctor's age and medical specialty, but not sex, influenced patterns of retention. Conclusion: Adjusting workforce participation by country of qualification can improve estimates of the number of medical school places needed to balance supply with demand. Developing countries undergoing strong economic growth are likely to be the most important suppliers of long stay medical migrants. ferrocenyl pyrazoles inhibit breast cancer cell viability via
 induction of apoptosis and inhibition of PI3K/Akt and ERK1/2

signaling CHEMICO-BIOLOGICAL INTERACTIONS English
 Article Ferrocene; Pyrazole;

Cell viability; Apoptosis; Necrosis; PI3K/Akt; ERK1/2

BIOLOGICAL EVALUATION; DERIVATIVES; POTENT; STATISTICS;

LIGANDS; SERIES; A549 Despite the advances in early detection and
 targeted therapies, chemotherapy is still of vital importance in

breast cancer treatment. However, development of drug resistance and serious side effects limits their usage. Thus, there is an urgent need for safer and more effective agents against breast cancer. We have previously described the synthesis of a number of pyrazole derivatives, and in the current study, we have investigated the effects of two different ferrocenyl pyrazole (FP) derivatives, 5-ferrocenyl-1-phenyl-1H-pyrazole (FP-Ph) and 5-ferrocenyl-1H-pyrazole (FP-H), on breast cancer cells. First, we investigated the effects of both FPs on cell viability and induction of cell death in breast cancer cells and benign MCF-10A cells by XTT and DNA fragmentation assays, respectively. Morphological changes in human breast cancer cells after FPs treatment were detected by both phase contrast microscope and atomic force microscopy (AFM). Then, we tested whether FPs exert their cytotoxic effect through inhibiting PI3K/Akt and/or ERK1/2 signaling pathways by using specific inhibitors. Both FPs induced cytotoxicity in a time and concentration-dependent manner in breast cancer cells; however, MCF-10A benign breast epithelial cells were much less susceptible to the cytotoxic effect of both FPs. FPs inhibited both PI3K/Akt and ERK 1/2 signaling pathways in breast cancer cells. The ultra structure images of MCF-7 cells by AFM showed that the cell surface was smooth in untreated cells, but it was rough with protrusions in treated cells. Both FPs induced apoptotic cell death in MDA-MB-231 cells; however, necrotic cell death was induced in caspase-3 lack MCF-7 cells, which implies that the synthesized FPs may induce apoptosis through caspase-3 dependent mechanism. In summary, these results suggest that FPs might be promising agents for the breast cancer therapy. (C) 2016 Elsevier Ireland Ltd. All rights reserved.

J Sabzalizadeh-Ardabili, S; Alizadeh-Navaei, R; Hedaytizadeh-Omran, A; Janbabaei, G Sabzalizadeh-Ardabili, Saeid; Alizadeh-Navaei, Reza; Hedaytizadeh-Omran, Akbar; Janbabaei, Ghasem Cancer Incidence and Mortality Pattern in Eastern Mediterranean Regional Office Countries and its Association with the Human Development Index CLINICAL CANCER

Cancer; Eastern Mediterranean Regional Office; Human Development Index; incidence; mortality TO-INCIDENCE RATIOS Purpose: Cancer is one of the main causes of death in the Eastern Mediterranean Regional Office (EMRO) region. The aim of this study was to determine the correlation between cancer incidence and mortality with the Human Development Index (HDI) in the EMRO region. Materials and Methods: The incidence and mortality rates of all cancers were obtained from the GLOBOCAN cancer project, and the data about the HDI were obtained from the United Nations Development Program database. The correlation between incidence, mortality rates, and the HDI parameters was analyzed by SPSS software. Results: The highest age-standardized incidence and mortality rates of cancers in the EMRO region were shown for colorectal cancer (10.19 +/- 5.30) and lung cancer (8.92 +/- 4.63), respectively, and the lowest was Kaposi's sarcoma in the incidence (0.20 +/- 0.14) and mortality rate (0.10 +/- 0.09), respectively. The lowest and highest incidence of all cancers in the region pertained to Yemen (80.40) and Lebanon (197.40), respectively. In addition, the lowest and highest mortality from all cancers were in Saudi Arabia (53.90) and Egypt (103.40), respectively. In examining the components of the HDI, gross national income per capita was related to mortality rate of all cancers ($P = 0.02$). The HDI was related between the incidence rates of colorectal, gallbladder, kidney, lip and oral cavity, multiple myeloma, esophagus, pancreas, and thyroid cancer and the mortality rates of lip and oral cavity, skin melanoma, multiple myeloma, nasopharynx, esophagus, larynx, and pancreas cancers ($P < 0.05$). Conclusion: The findings of the present study showed that the incidence and mortality rates of some cancers were related to HDI, and the highest correlation was found between the incidence of kidney cancer and the mortality of pancreatic cancer with HDI.

between overall diet quality and postmenopausal breast cancer risk
in five Finnish cohort studies SCIENTIFIC REPORTS

English Article

BALTIC SEA DIET; FOOD FREQUENCY QUESTIONNAIRE; HEALTHY
NORDIC DIET; MEDITERRANEAN DIET; ADHERENCE; DISEASE; METAANALYSIS;
VALIDITY; WOMEN; INDEX There is limited evidence for any dietary
factor, except alcohol, in breast cancer (BC) risk. Therefore,
studies on a whole diet, using diet quality indices, can broaden
our insight. We examined associations of the Nordic Diet (mNDI),
Mediterranean diet (mMEDI) and Alternative Healthy Eating Index
(mAHEI) with postmenopausal BC risk. Five Finnish cohorts were
combined including 6374 postmenopausal women with dietary
information. In all, 8-9 dietary components were aggregated in
each index, higher total score indicating higher adherence to a
healthy diet. Cox proportional hazards regression was used to
estimate the combined hazard ratio (HR) and 95% confidence
interval (CI) for BC risk. During an average 10-year follow-up
period, 274 incident postmenopausal BC cases were diagnosed. In
multivariable models, the HR for highest vs. lowest quintile of
index was 0.67 (95 %CI 0.48-1.01) for mNDI, 0.88 (0.59-1.30) for
mMEDI and 0.89 (0.60-1.32) for mAHEI. In this combined dataset, a
borderline preventive finding of high adherence to mNDI on
postmenopausal BC risk was found. Of the indices, mNDI was more
based on the local food culture than the others. Although a
healthy diet has beneficially been related to several chronic
diseases, the link with the etiology of postmenopausal BC does not
seem to be that obvious. [Mannisto, Satu; Harald, Kennet;

J Souiai, O; Sallemi, A Souiai, Oussama;
Sallemi, Ameni Retrospective Phylodynamic and
Phylogeographic Analysis of the Human Papillomavirus 16 E6 Gene in
the Mediterranean Region BIOINFORMATICS AND BIOLOGY INSIGHTS
English Article
HPV16; E6; phylogeography; evolution; substitution rate
INFECTION; RISK Human papillomavirus 16 (HPV16) is
considered to be strongly correlated with the development of
cervical cancer. Among the 8 HPV16 genes, the E6 constitutes a
remarkable marker to follow the evolutionary history and spatial
phylogenetics of HPV16 in the Mediterranean basin. Thus, this work
aims to decipher the major evolutionary events and crosstalks in
the Mediterranean basin with a focus on Tunisian strains regarding
the E6 oncogene. In this study, we first extracted the available
and annotated Mediterranean strains of HPV16 E6 gene sequences (n
= 155) from the NCBI nucleotide database. These sequences were
aligned, edited, and used for the downstream phylogenetic
analyses. Finally, a Bayesian Markov Chain Monte Carlo approach
was applied to reconstruct the evolutionary history of HPV16
migration. Our results showed that the HPV circulating in Tunisia
derived from a Croatian ancestor around the year 1987. This
starting point spreads to most European countries to reach
northern Africa through the Moroccan gateway in 2004. [Souiai,

 Piccitto, Giorgio; Avola, Maurizio; Panichella, Nazareno
 Migration, social stratification, and labor market
 attainment: An analysis of the ethnic penalty in 12 Western
 European countries INTERNATIONAL JOURNAL OF COMPARATIVE
 SOCIOLOGY English Article
 Inequality; labor market attainment; migration;
 occupation; stratification OCCUPATIONAL INTEGRATION; ECONOMIC
 INCORPORATION; RECENT IMMIGRANTS; MOBILITY; SOCIETIES; EDUCATION;
 MIGRANTS; ORIGINS This article presents a comprehensive
 investigation into the socioeconomic integration of migrants
 across 12 Western European countries, considering their likelihood
 of employment and socioeconomic status. Using the data from the
 European Social Survey, the study employs linear regression and
 probit models to achieve two aims: (a) to quantify the penalty for
 male and female migrants in terms of employment and socioeconomic
 status attainment; (b) to assess how the ethnic penalty for men
 and women changes based on their education and social background
 of origin. Results reveal that male and female migrants face a
 penalty in most countries under consideration, albeit with varying
 degrees of magnitude and characteristics. Migrants in Southern
 European countries exhibit a trade-off between employment and
 socioeconomic status attainment, while those in Central-Northern
 Europe experience a double penalty on both outcomes. Moreover, it
 emerges that the ethnic penalty in labor market attainment is more
 heterogeneous across migrants with different educational levels
 than with different social classes of origin: migrants' social
 background of origin affects to a lesser extent their labor market
 outcomes, if compared with their human capital. Migrants with high
 education and social origin suffer the largest penalty, due to
 hurdles in leveraging their educational qualifications and social
 position. This pattern is particularly evident in Southern Europe,
 where the socioeconomic integration of migrant workers is
 characterized by a leveling-down process, pushing them into the
 lowest strata of the occupational hierarchy regardless of their
 education and social background. [Piccitto, Giorgio] Univ Milano

Turkish Article

Human papillomavirus (HPV); HPV vaccine; cervical cancer HUMAN-PAPILLOMAVIRUS INFECTION; CERVICAL-CANCER; ACCEPTABILITY; PREVENTION; PREDICTORS Objective: To investigate the awareness about human papillomavirus (HPV) and acceptance of HPV vaccine among women who present to gynecology outpatient clinics at a tertiary referral hospital in South Mediterranean region of Turkey. Materials and Methods: A total of 426 women aging between 18 and 65 who applied to gynecology outpatient clinics between January and April 2015 were included in analysis in order to evaluate the awareness and knowledge about HPV infection and vaccination. In the present study, "Participant Knowledge Form" and "HPV Knowledge Evaluation Questionnaire" were used, which were developed by authors after analyzing the relevant literature. Study data were analyzed with SPSS 21 computer software. Descriptive statistics were presented as mean +/- standard deviation, and number (percentage). Results: Among 426 participants that were included in the study, mean age was 32.3 +/- 10.1 years. Two hundred and fifty-eight (60.6%) stated that they have not heard about HPV, whereas 168 (39.4%) stated otherwise. On the other hand, 141 participants (33.1%) heard about HPV vaccine. HPV vaccination was accepted by 182 (42.7%) participants, whereas 244 (57.3%) women did not accept vaccination. Conclusion: In the present study, it was concluded that women who present to gynecology outpatient clinics did not have adequate knowledge about HPV infection and HPV vaccination. For the purposes of public health education, written, verbal and visual educational programs should be implemented at schools, hospitals and internet.

cancer (PCa) mortality rates are lower in the Mediterranean
countries compared with northern Europe. Although specific
components of the Mediterranean diet (Med-Diet) may influence PCa
risk, few studies have assessed the traditional Med-Diet pattern
with the risk of incident advanced or lethal PCa or with disease
progression among men diagnosed with nonmetastatic PCa. Objective:
To determine whether the traditional Med-Diet pattern is
associated with risk of incident advanced or lethal PCa and with
PCa-specific and overall mortality among men with PCa. Design,
setting, and participants: We prospectively followed 47 867 men in
the Health Professionals Follow-up Study followed from 1986 to
2010. The case-only analysis included 4538 men diagnosed with
nonmetastatic PCa, followed from diagnosis to lethal outcome or to
January 2010. Outcome measurements and statistical analysis: We
used Cox proportional hazards models to examine traditional and
alternative Med-Diet scores in relation to PCa incidence outcomes
(advanced and lethal disease). In a case-only survival analysis,
we examined postdiagnostic Med-Diet and risk of lethal (metastases
or PCa death) and fatal PCa as well as overall mortality among men
diagnosed with nonmetastatic disease. Results and limitations:
Between 1986 and 2010, 6220 PCa cases were confirmed. The Med-Diet
was not associated with risk of advanced or lethal PCa. In the
case-only analysis, there was no association between the Med-Diet
after diagnosis and risk of lethal or fatal PCa. However, there
was a 22% lower risk of overall mortality (hazard ratio: 0.78; 95%
confidence interval, 0.67-0.90; p(trend) = 0.0007) among men with
greater adherence to the Med-Diet after PCa diagnosis. We found
similar associations for the alternative score. Conclusions: A
higher Med-Diet score was not associated with risk of advanced PCa
or disease progression. Greater adherence to the Med-Diet after
diagnosis of nonmetastatic PCa was associated with lower overall
mortality. (C) 2013 European Association of Urology. Published by

Relationship between material needs security and clinical outcomes in adults with type 2 diabetes in Lebanon DIABETES RESEARCH AND CLINICAL PRACTICE English Article

Type 2 diabetes; Material Needs Security; Glycemic control; Hemoglobin A1c; Blood pressure; Lebanon SOCIOECONOMIC-STATUS; SOCIAL DETERMINANTS; SELF-EFFICACY; HEALTH; CARE; ASSOCIATION Background: Despite their documented significance in type 2 diabetes (T2DM) management, social determinants of health (SDOHs) including material needs security are poorly studied in the Middle East and North Africa (MENA) region. This study aims to assess the relation between material needs security and clinical outcomes in Lebanese adults with T2DM. Methods: Subjects with T2DM (n = 300) were recruited; demographic and material need variables were collected using self-reported questionnaires. Measured clinical outcomes included Hemoglobin A1c (A1C), systolic (SBP) and diastolic blood pressure (DBP). Regression models were used to examine associations between material needs security and clinical outcomes, controlling for relevant confounding variables. Results: Most of the participants were men, married and with lower education levels. Having higher material needs security and being employed predicted better A1C levels (p < 0.05), whereas male sex was associated with poorer A1C (ss = 0.52, p = 0.03) and DBP (ss = 3.06, p = 0.05). Other predictors of DBP included older age and lack of confidence in filling out medical forms, reflecting lower health literacy. Conclusions: Our study highlights the importance of material needs in achieving optimal T2DM outcomes T2DM in the MENA region. Further research is needed to understand potential pathways/mechanisms and options for effective interventions.

COVID-19 vaccine hesitancy among undocumented
migrants during the early phase of the vaccination campaign: a
multicentric cross-sectional study BMJ OPEN

English Article COVID-19;

Health policy; GENERAL MEDICINE (see Internal Medicine) UNITED-
STATES; DEATHS; DISPARITIES; IMMIGRANTS; ETHNICITY; HEALTH; CARE;
RACE; AGE Study objectives The marginalisation of undocumented
migrants raises concerns about equitable access to COVID-19
vaccination. This study aims to describe migrants' hesitancy about
the COVID-19 vaccination during the early phase of the vaccination
campaign. Setting This multicentric cross-sectional survey was
conducted in health facilities providing care to undocumented
migrants in the USA, Switzerland, Italy and France in February-May
2021. Participants Eligibility criteria included age >16 years,
being of foreign origin and living without valid residency permit
in the country of recruitment. A convenience sample of minimum 100
patients per study site was targeted. Primary and secondary
outcome measures Data were collected using an anonymous structured
questionnaire. The main outcomes were perceived access to the
local COVID-19 vaccination programme and demand for vaccination.
Results Altogether, 812 undocumented migrants participated (54.3%
Geneva, 17.5% Baltimore, 15.5% Milano and 12.7% Paris). Most
(60.9%) were women. The median age was 39 years (interquartile
range 1). Participants originated from the Americas (55.9%),
Africa (12.7%), Western Pacific (11.2%) Eastern Mediterranean
(7.9%), Europe (7.6%) and South-East Asia (4.7%). Overall, 14.1%
and 26.2% of participants, respectively, reported prior COVID-19
infection and fear of developing severe COVID-19 infection. Risk
factors for severe infection were frequently reported (29.5%).
Self-perceived accessibility of COVID-19 vaccination was high
(86.4%), yet demand was low (41.1%) correlating with age,
comorbidity and views on vaccination which were better for
vaccination in general (77.3%) than vaccination against COVID-19
(56.5%). Participants mainly searched for information about
vaccination in the traditional and social media. Conclusions We
found a mismatch between perceived accessibility and demand for
the COVID-19 vaccination. Public health interventions using

different communication modes should build on trust about vaccination in general to tackle undocumented migrants' hesitancy for COVID-19 vaccination with a specific attention to men, younger migrants and those at low clinical risk of severe infection.

to the Mediterranean diet assessed by a novel dietary biomarker
score and mortality in older adults: the InCHIANTI cohort study
BMC MEDICINE English Article

Dietary biomarkers; Older adults;
Mediterranean diet; Mortality; Polyphenols; Carotenoids; Dietary
questionnaires PLASMA CAROTENOIDS; TOCOPHEROL CONCENTRATIONS;
MUSCLE STRENGTH; NUTRIENT INTAKE; BREAST-CANCER; FATTY-ACIDS;
NUTRITION; ASSOCIATIONS; POLYPHENOLS; RISK Background: Dietary
biomarkers may complement dietary intake assessment made by
dietary questionnaires. We developed an a-posteriori dietary
biomarkers score based on Mediterranean diet food groups and
evaluated its association with mortality. Methods: 642
participants (56% female), aged ≥ 65 years, with complete data on
dietary biomarkers were followed during 20 years in the InCHIANTI
cohort study (Tuscany, Italy). The main outcomes were all-cause,
cardiovascular, and cancer mortality. Dietary biomarkers were
selected from literature and from correlation analyses with
dietary intakes of Mediterranean diet food groups in the study.
The baseline levels of the following dietary biomarkers were
chosen: urinary total polyphenols and resveratrol metabolites, and
plasma carotenoids, selenium, vitamin B12, linolenic,
eicosapentaenoic and docosahexaenoic acids, and the mono-
unsaturated/saturated fatty acid ratio. Associations of the
Mediterranean diet score using dietary biomarkers and a validated
food frequency questionnaire (FFQ) (as tertiles) with mortality
were assessed through Cox regression. Results: During the 20-year
follow-up [median (Q1-Q3), 14 (8-18) years], and 435 deaths
occurred (139 from cardiovascular diseases and 89 from cancer-
related causes). In the fully adjusted models, the dietary
biomarker-Mediterranean diet score was inversely associated with
all-cause (HRT3vs.T1 0.72; 95%CI 0.56-0.91) and cardiovascular
(HRT3vs.T1 0.60; 95%CI 0.38-0.93), but not with cancer mortality.
Associations between the FFQ-Mediterranean diet score and
mortality were not statistically significant. Conclusions: A
greater adherence at baseline to a Mediterranean diet assessed by
a dietary biomarker score was associated with a lower risk of
mortality in older adults during a 20-year follow-up. The
measurement of dietary biomarkers may contribute to guide
individualized dietary counseling to older people. [Hidalgo-

English Article Natural products; Terpenoids; Structure elucidation; Medicinal chemistry
QUINONES; STEREOCHEMISTRY Chemical investigation of the Mediterranean ascidian *A. conicum* resulted in the isolation of two new meroterpenes, the conithiaquinones A (1) and B (2), in addition to two previously reported chromenols (3 and 4) and conicaquinones (5 and 6). The structures of conithiaquinones A and B were determined by interpretation of spectroscopic data, and regiochemical and stereochemical assignments were achieved with the aid of computational methods, including the recently developed DP4 NMR spectral prediction method. Both conithiaquinones A and B showed significant effects on the growth and viability of cells, with 1 showing interesting cytotoxicity against human breast cancer cells. Mediterranean-Style Dietary Pattern and Risk of Esophageal
Squamous Cell Carcinoma: A Case-Control Study in Iran JOURNAL
OF THE AMERICAN COLLEGE OF NUTRITION English
Article esophageal squamous
cell carcinoma; Iran; Mediterranean-Style Dietary Pattern Score
(MSDPS) BREAST-CANCER RISK; AERODIGESTIVE TRACT CANCER;
GUIDELINES-FOR-AMERICANS; MAJOR CHRONIC DISEASE; FOOD GROUP
INTAKE; PHYSICAL-ACTIVITIES; RELATIVE VALIDITY; SELF-REPORT;
POPULATION; SURVIVAL Objective: The benefit of adherence to a
Mediterranean-style dietary pattern in relation to the risk of
esophageal squamous cell carcinoma (ESCC) has not been
investigated among non-Mediterranean high-risk populations. The
objective of the present study was to examine the association of
compliance with the Mediterranean dietary pattern as measured by
Mediterranean-Style Dietary Pattern Score (MSDPS) and the risk of
ESCC in Iranian population. Methods: This case-control study was
conducted on 47 ESCC cases and 96 hospital controls aged 40-75
years. Participants were interviewed using validated
questionnaires, and dietary patterns were characterized using the
MSDPS. Results: Generally, the mean MSDPS in this population was
low (30.84 +/- 8.58). MSDPS showed content validity through having
expected positive associations with several lifestyle
characteristics and dietary intakes. Being in the highest quartile
category of MSDPS, compared to the lowest, was independently
associated with 37% reduction in risk of ESCC. Two-unit and 3-unit
increases in the MSDPS resulted in 41% and 47% reduction in risk
of ESCC, respectively. Higher intakes of olive oil (odds ratio
[OR] = 0.15, 95% CI: 0.01-0.49), fish and other seafood (OR =
0.48, 95% CI: 0.23-0.98), whole grain (OR = 0.57, 95% CI: 0.28-
0.76), and fruits (OR = 0.77, 95% CI: 0.38-0.86) were
significantly associated with reduced ESCC risk. In contrast,
higher sweet (OR = 1.86, 95% CI: 1.04-2.12) and meat intakes (OR =
1.61, 95% CI: 1.25-2.49) were associated with higher ESCC risk.
Conclusion: Consuming a diet in concordance with the principles of
the Mediterranean dietary pattern may protect against ESCC.
Preventive strategies to reduce ESCC risk in high-risk countries
should focus on overall dietary pattern and dietary habits to be
effective. [Jessri, Mahsa] Univ Alberta Edmonton, Div Human Nutr,

Respecting and protecting the lives of migrants and
refugees: the need for a human rights approach to save lives and
find missing persons INTERNATIONAL JOURNAL OF HUMAN RIGHTS
English Article

International law; refugees; migrants; missing persons;
human rights; Europe IDENTIFICATION; MIGRATION; CONFLICT;
POLITICS; VICTIMS; BORDERS; DEATHS; RESCUE; SEA The world is in
a migration crisis. Thousands of people are dying annually trying
to get across the Mediterranean. However, this is not a problem
unique to Europe. It has remained a hidden global problem for a
long time. What is specifically unknown are the numbers of people
who have gone missing while migrating. This article therefore
focuses on such missing people. It examines the numbers of people
that are known to have died, and argues that there is a general
dearth of information about both people who have died, as well as
those who have gone missing. The article reviews who missing
people are and argues that the term missing is only found to any
large measure in the laws of armed conflict, and most other
situations that cause people to go missing, those who are subject
to enforced disappearances, are not covered. The article argues
that more research ought to be done on these issues and more data
ought to be collected and analysed. It argues that people on
migration routes are vulnerable and further argues that more needs
to be done to provide them with protection and assistance. The
laws dealing with the missing are analysed. The article argues
that a human rights approach is needed to deal with the problem
and that states need to play much more of a compassionate and
humane role concerning migration matters and missing people
generally and specifically. The article also argues for
partnerships and coordination, that the families need to be given
more support, and that more public education is needed to deal
with the negative perceptions and misconceptions that exist in
many societies to which those migrating seek to move to, as this

will give greater positive impetus to states to deal more appropriately with those who migrate for whatever reason.

Manipulating macrophage polarization with nanoparticles to control metastatic behavior in heterotypic breast cancer micro-tissues via exosome signaling NANOSCALE English Article ACTIVATING

MACROPHAGES; IMMUNITY; PATHWAY; OXIDE This study aimed to investigate the effects of nanoparticles on macrophage polarization and their subsequent influence on post-tumorigenic behavior. Initially, seven different nanoparticles were applied to macrophages, and Zn-Ni-FeO (100 nm) and palladium nanoparticles (PdNPs, similar to 25 nm) were found to induce M1-polarization in macrophages. A co-culture experiment was then conducted to examine the effects of macrophages on MCF-7 breast cancer micro-tissues. The M2-macrophages promoted tumor proliferation, while M1- and PdNPs-induced macrophages showed anti-tumor effects by suppressing cell proliferation. To reveal the mechanisms of effect, exosomes isolated from M1 (M1-Exo), M0 (M0-Exo), M2 (M2-Exo), and PdNPs-induced (PdNPs-Exo) macrophages were applied to the heterotypic tumor micro-tissues including MCF-7, human umbilical vein endothelial cells (HUVECs), and primary human dermal fibroblasts (phDFs). M2-Exo was seen to promote the migration of cancer cells and induce epithelial-mesenchymal transition (EMT), while M1-Exo suppressed these behaviors. PdNPs-Exo was effective in suppressing the aggressive nature of breast cancer cells similar to M1-Exo, moreover, the efficacy of 5-fluorouracil (5-FU) was increased in combination with PdNPs-Exo in both MCF-7 and heterotypic micro-tissues. In conclusion, PdNPs-Exo has potential anti-tumor effects, can be used as a combination therapy to enhance the efficacy of anti-cancer drugs, as well as innovative implants for breast cancer treatment. J Hermansyah, D; Pricilia, G; Simamora, Y; Siregar, DR
 Hermansyah, Dedy; Pricilia, Gracia; Simamora,
 Yolanda; Siregar, Denny Rifsal Clinicopathological
 Characteristics of Patients with BRCA Mutation Breast Cancer in
 North Sumatera: Case Report MIDDLE EAST JOURNAL OF CANCER
 English Article

Breast neoplasms; Genes; BRCA1; BRCA2; Immunohistochemistry

The most common cancer in women is breast cancer (BC) with an incidence of 24.2%. BC in younger patients will in general be more forceful, prompting more awful results and a requirement for more forceful treatment which may bring about a higher probability of long-haul treatment-related harmfulness and novel psychosocial issues. Furthermore, family inclination to BC as BRCA1 and BRCA2 mutations is more prevalent in this age group. There were a total of five ladies who had tumor pathology testing with negative results. All intrusive BC examples were regularly assessed for estrogen receptor, progesterone receptor, and human epidermal growth factor receptor-2 (HER2)/neu status utilizing immunohistochemistry. Cases with HER2/neu staining of 1+, 2+ or 3+ on immunohistochemistry examination were additionally assessed by fluorescent in situ hybridization for the enhancement of the HER2/neu quality. In this examination, we distinguished clinicopathological attributes of patients with BC. We partitioned into two gatherings, BRCA positive change and BRCA negative transformation. Roughly 5%-10% instances of BC have a positive family ancestry and about 20%-40% BC development were in acquired

variations. Our study revealed that 20% of cases included individuals who had a family history of BRCA mutation. Male relatives with BC, earlier age at onset, a greater prevalence of reciprocal breast disease, and a connection to various malignancies in the ovary, colon, prostate, pancreas, and endometrial are only a few of the clear clinical characteristics of BRCA1/2-related BC. Nordic diet, Mediterranean diet, and the risk of chronic diseases: the EPIC-Potsdam study BMC MEDICINE

English Article

Mediterranean diet; Nordic diet; regional diets; chronic diseases; diabetes; myocardial infarction; stroke; cancer; EPIC-Potsdam study; longitudinal analysis FOOD-FREQUENCY QUESTIONNAIRE; BALTIC SEA DIET; BREAST-CANCER RISK; CARDIOVASCULAR-DISEASE; COLORECTAL-CANCER; NO ASSOCIATION; ADHERENCE; INDEX; WOMEN; METAANALYSIS Background: The Mediterranean Diet (MedDiet) has been acknowledged as a healthy diet. However, its relation with risk of major chronic diseases in non-Mediterranean countries is inconclusive. The Nordic diet is proposed as an alternative across Northern Europe, although its associations with the risk of chronic diseases remain controversial. We aimed to investigate the association between the Nordic diet and the MedDiet with the risk of chronic disease (type 2 diabetes (T2D), myocardial infarction (MI), stroke, and cancer) in the EPIC-Potsdam cohort. Methods: The EPIC-Potsdam cohort recruited 27,548 participants between 1994 and 1998. After exclusion of prevalent cases, we evaluated baseline adherence to a score reflecting the Nordic diet and two MedDiet scores (tMDS, reflecting the traditional MedDiet score, and the MedPyr score, reflecting the MedDiet Pyramid). Cox regression models were applied to examine the association between the diet scores and the incidence of major chronic diseases. Results: During a follow-up of 10.6 years, 1376 cases of T2D, 312 of MI, 321 of stroke, and 1618 of cancer were identified. The Nordic diet showed a statistically non-significant inverse association with incidence of MI in the overall population and of stroke in men. Adherence to the MedDiet was associated with lower incidence of T2D (HR per 1 SD 0.93, 95% CI 0.88-0.98 for the tMDS score and 0.92, 0.87-0.97 for the MedPyr score). In women, the MedPyr score was also

inversely associated with MI. No association was observed for any of the scores with cancer. Conclusions: In the EPIC-Potsdam cohort, the Nordic diet showed a possible beneficial effect on MI in the overall population and for stroke in men, while both scores reflecting the MedDiet conferred lower risk of T2D in the overall population and of MI in women. Integrative systems-level analysis reveals a contextual crosstalk between hypoxia and global metabolism in human breast tumors

MOLECULAR ONCOLOGY English Article

breast cancer; cancer metabolism; hypoxia; systems biology; Warburg effect AEROBIC GLYCOLYSIS; CANCER CELLS; REQUIREMENTS; THERAPY; GROWTH Hypoxia is known to induce reprogramming of glucose metabolism in cancer. However, the impact of hypoxia on global metabolism remains poorly understood. Here, using the systems approach, we evaluated the potential crosstalk between hypoxia and global metabolism using data from > 2000 breast tumors. Tumor samples were scored for hypoxia and 90 metabolic pathways, and these metrics were subjected to an analysis pipeline. Hypoxia showed a very strong association with metabolic aggression and an overall contextual relationship with metabolism. Out of three (M1, M2, and M3) metabolic types in breast cancer, M3 exhibited the strongest relationship with hypoxia; that is, high hypoxic tumors were also metabolically deregulated. Further, the overall correlation pattern between hypoxia and metabolic pathway scores was specific to each type, with M1 showing maximal sensitivity to hypoxia, followed by M2 and then M3. Experimental validation using metabolic inhibitors on cell lines with high or low hypoxia scores further confirmed the metabolic type-dependence of hypoxia. In addition, evaluation of the impact of hypoxia on cancer pathways other than metabolic ones revealed a potential role of hypoxia in immune evasive characteristic of M3 tumors. Overall, the results suggest a complex interplay between hypoxia and metabolism in the context of human breast tumors, with potential implications for both basic cancer biology and breast cancer therapy. J Genovese, C; Garozzo, A; D'Angeli, F; Malfa, GA; Bellia, F; Tomasello, B; Nicolosi, D; Malaguarnera, R; Ronsisvalle, S; Guadagni, F; Acquaviva, R Genovese, Carlo; Garozzo, Adriana; D'Angeli, Floriana; Malfa, Giuseppe Antonio; Bellia, Francesco; Tomasello, Barbara; Nicolosi, Daria; Malaguarnera, Roberta; Ronsisvalle, Simone; Guadagni, Fiorella; Acquaviva, Rosaria Orobanche crenata Forssk. Extract Affects Human Breast Cancer Cell MCF-7 Survival and Viral ReplicationCELLS English Article

Orobanche crenata extract; MCF-7 cells; MDA-MB-231 cells; Herpes simplex virus; Cocksackievirus; parasitic plant CYCLE ARREST; IN-VITRO; ANTIVIRAL ACTIVITY; LUTEOLIN; ANTIOXIDANT; SALIDROSIDE; APOPTOSIS; APIGENIN; THERAPY; L.

Background: Breast cancer (BC) is the leading cause of death worldwide. The severity of BC strictly depends on the molecular subtype. The less aggressive hormone-positive subtype is treated with adjuvant endocrine therapy (AET), which causes both physical and psychological side effects. This condition strongly impacts the adherence and persistence of AET among oncologic patients. Moreover, viral infections also constitute a serious problem for public health. Despite their efficacy, antiviral agents present several therapeutic limits. Accordingly, in the present work, we investigated the antitumor and antiviral activities of *Orobanche crenata* Forssk. (*O. crenata*), a parasitic plant, endemic to the Mediterranean basin, traditionally known for its beneficial properties for human health. Methods: The MTT assay was carried out to evaluate the cytotoxic effect of *O. crenata* leaf extract (OCLE) on human breast cancer cells (MCF-7 and MDA-MB-231) and the primary HFF-1 cell line. The lactic dehydrogenase (LDH) assay was performed on MCF-7 cells to analyze necrotic cell death. The antioxidant effect of OCLE was evaluated by intracellular determination of the reactive oxygen species and thiol groups, by DPPH and ABTS assays. The antiviral activity of OCLE was determined against Poliovirus 1, Echovirus 9, Human respiratory syncytial virus, Adenovirus type 2 and type 5, Cocksackievirus B1 (CoxB1) and B3 (CoxB3), Herpes simplex type 1 (HSV-1) and type 2 (HSV-2), and beta-Coronavirus by the plaque reduction assay. Results: The extract, after 24 h of incubation, did not affect MDA-MB-231 and HFF-1 cell viability. However, at the same time point, it showed a dose-dependent inhibitory effect on MCF-7 cells, with an increase in LDH release. OCLE exhibited free radical scavenging activity and significantly increased non-protein thiol levels in MCF-7 cells. OCLE effectively inhibited HSV-1, HSV-2, CoxB1, and CoxB3 replication. Conclusions: The overall results showed an interesting inhibitory effect of OCLE on both MCF-7 cell survival and viral replication. A Mimicry of the Tumor Microenvironment's Impact on SLC4A7 (NBCn1) and Caspase-3 Gene Expression in Breast Cancer, along with in Silico Traits of NBCn1 MIDDLE EAST JOURNAL OF CANCER

English Article

Tumor microenvironment; Caspase-3; Breast neoplasms; In silico COTRANSPORTER NBCN1; NA+/H+ EXCHANGER; NHE1

Background: This study investigates the relative expression of the Na⁺, HCO³⁻ cotransport gene NBCn1, and caspase-3 within the tumor microenvironment of human breast cancer, considering the in vivo microenvironment. Method: In this experimental study, breast cancer MDA-MB-231 cells were cultured under normoxia/hypoxia conditions for 24, 48, and 72 hours with varying glucose concentrations (5.5, 11, and 25 mM). The mRNA expression of NBCn1 and caspase-3 was evaluated using real-time polymerase chain reaction. The stability and binding pocket of NBCn1 were assessed using DisPhred and the Computed Atlas of Surface Topography of proteins (CASTp) servers, respectively. The location prediction of the protein was determined using the Transmembrane Helices; Hidden Markov Model (TMHMM) server. Results: Normoxia led

to an increase in NBCn1 expression during all three time periods, displaying heterogeneity. The expression was particularly elevated at glucose concentrations of 25 and 5.5 mM. In hypoxic conditions, gene expression was reduced; however, an increase in glucose concentration enhanced SLC4A7 expression. Specifically, a glucose concentration of 25 mM led to decreased caspase-3 expression under hypoxic conditions. In silico studies revealed that SLC4A7 becomes disordered when the pH falls below 7, with most amino acids in the binding pocket being nonpolar. Conclusion: The heightened risk of breast cancer metastasis may be linked to the upregulation of SLC4A7 and downregulation of caspase-3 expression, underscoring their fundamental roles in cancer treatment and prevention. SLC4A7 is a transmembrane protein, and its folding is pH-dependent.

J Daoud, N; Osman, A; Hart, TA; Berry, EM; Adler, B Daoud, Nihaya; Osman, Amira; Hart, Trevor A.; Berry, Elliott M.; Adler, Bella Self-care management among patients with type 2 diabetes in East Jerusalem HEALTH EDUCATION JOURNAL English Article Health Belief Model; low-income populations; Middle East; self-care management; type 2 diabetes HEALTH; POPULATION; BEHAVIORS; MELLITUS; BARRIERS; BELIEFS Objective: Little research exists on diabetes self-care management (DSCM) in Arab populations. We examined the contribution of health belief constructs, socioeconomic position (SEP) and clinical factors (glycated haemoglobin [HbA1C] level, type of diabetes treatments, and receiving professional guidance) to DSCM among Arab patients in East Jerusalem with type 2 diabetes. Method: Using a structured questionnaire, we conducted face-to-face interviews with a random sample of 230 patients with type 2 diabetes in a large diabetes clinic. DSCM included engagement in any of the following in the last week: physical activity, consumption of low-fat and low-sugar diet, self-

monitoring of blood glucose, medication uptake and foot care. We obtained HbA1C levels from the clinic's patient registry. We used linear regression to examine the contribution of health beliefs, SEP and clinical factors to explaining DSCM. Results: Adherence to DSCM was low. Most patients (84.8%) were physically inactive, 64.3% did not consume a low-fat or low-sugar diet (46.5%) and 51% did not self-monitor blood glucose. However, medication adherence (95.7%) and foot care were high (77.4%). About 71% of participants had high HbA1C (>7.0%). In the multivariate analysis, total DSCM scores were higher among patients with low financial barriers, high perception of the benefits of DSCM and higher self-efficacy. Patients using oral medication (vs insulin) had significantly lower DSCM scores. Conclusion: Among Arab patients with diabetes, more interventions are needed to encourage DSCM, specifically in areas of lifestyle (diet and physical activity). Patients' financial barriers, benefits of DSCM and patient self-efficacy should be emphasised. MicroRNAs and Drinking: Association between the Pre-miR-27a rs895819

microRNAs; alcohol; miR27a; Mediterranean SINGLE
NUCLEOTIDE POLYMORPHISMS; GASTRIC-CANCER SUSCEPTIBILITY;
FUNCTIONAL POLYMORPHISM; MENDELIAN RANDOMIZATION; COLORECTAL-
CANCER; GENETIC VARIANT; RISK; EXPRESSION; MIR-27A; DIET Recently,
microRNAs (miRNA) have been proposed as regulators in the
different processes involved in alcohol intake, and differences
have been found in the miRNA expression profile in alcoholics.
However, no study has focused on analyzing polymorphisms in genes
encoding miRNAs and daily alcohol consumption at the population
level. Our aim was to investigate the association between a
functional polymorphism in the pre-miR-27a (rs895819 A>G) gene and
alcohol consumption in an elderly population. We undertook a
cross-sectional study of PREvencion con DIeta MEDiterranea
(PREDIMED)-Valencia participants (n = 1007, including men and
women aged 67 +/- 7 years) and measured their alcohol consumption
(total and alcoholic beverages) through a validated questionnaire.
We found a strong association between the pre-miR-27a polymorphism
and total alcohol intake, this being higher in GG subjects (5.2
+/- 0.4 in AA, 5.9 +/- 0.5 in AG and 9.1 +/- 1.8 g/day in GG;
p(adjusted) = 0.019). We also found a statistically-significant
association of the pre-miR-27a polymorphism with the risk of
having a high alcohol intake (> 2 drinks/day in men and > 1 in
women): 5.9% in AA versus 17.5% in GG; p(adjusted) < 0.001. In the
sensitivity analysis, this association was homogeneous for sex,
obesity and Mediterranean diet adherence. In conclusion, we report
for the first time a significant association between a miRNA
polymorphism (rs895819) and daily alcohol consumption.

INTEGRATION: POSITIVE AND NEGATIVE PERCEPTIONS (CASE OF TORNIO,
FINLAND) GEOGRAPHIA POLONICA English Article
cultural integration; migration;

newcomer; asylum seeker; host community; Tornio IMMIGRANT INCORPORATION; ACCULTURATION; ASSIMILATION; MIGRATION Increase in the migration flows has become a challenge in the world today. In Finland there is considerable shift in the number of migrants from Africa and the Middle East countries. The paper is based on the sociological research conducted in August-September, 2016 in Tornio (Finland). The empirical observations were gained from the interviews with 12 migrants and the questionnaires on the city Tornio attractiveness (73 locals) and the human mobility challenges (89 locals). The obtained results highlight the significant role of the communication activities with the joint participation of locals and newcomers in understanding each others' culture, decreasing negative perceptions and reactions in the integration process. J Stone, RAT; Waring, ME; Cutrona, SL; Kiefe, CI; Allison, J; Doubeni, CA Stone, Rosalie A. Torres; Waring, Molly E.; Cutrona, Sarah L.; Kiefe, Catarina I.; Allison, Jeroan; Doubeni, Chyke A. The association of dietary quality with colorectal cancer among normal weight, overweight and obese men and women: a prospective longitudinal study in the USA BMJ OPEN English Article FOOD-FREQUENCY QUESTIONNAIRE; HEALTH-AMERICAN-ASSOCIATION; RETIRED-PERSONS DIET; NIH-AARP DIET;

MEDITERRANEAN DIET; UNITED-STATES; NATIONAL-INSTITUTES; RECTAL-CANCER; RISK-FACTORS; ALL-CAUSE Objective Lower body mass index (BMI) and higher dietary quality reduce the risk of colorectal cancer (CRC). A full understanding of how these associations vary by sex and weight is lacking. Methods We used data from the National Institutes of Health - American Association of Retired Persons (NIH)-AARP) Diet and Health Study for 398 458 persons who were 50-71 years old in 1995-1996 and followed through 2006. Exposures were dietary quality as reflected by the Mediterranean Diet, the Healthy Eating Index-2010 and the Dietary Approaches to Stop Hypertension score, stratified by BMI category. The outcome was CRC diagnosis from cancer registry data. Cox regression models were adjusted for disease risk factors. Results Over a mean duration of 123 months of follow-up, there were 6515 new diagnoses of CRC (1953 among the normal weight, 2924 among the overweight and 1638 among the obese; 4483 among men and 2032 among women). For normal weight and overweight men, we found a strong dose-response pattern for the association of increasing quintile of dietary quality with decreasing risk of CRC; this pattern was observed for obese men as well, but less consistently across the three measures of dietary quality. The findings were of smaller magnitude and less consistent for women but still suggesting associations of similar direction. Conclusion We observed that increased dietary quality was associated with lower risk of incident CRC up to 10 years later for men regardless of baseline weight category. [Stone, Rosalie A. Mediterranean diet and risk of pancreatic cancer in the European Prospective Investigation into Cancer and Nutrition cohort BRITISH JOURNAL OF CANCER English Article

Mediterranean diet; pancreatic cancer; cohort study
 BREAST-CANCER; ADHERENCE; PATTERNS; METAANALYSIS;
 CONSUMPTION; COUNTRIES; MORTALITY; DEATHS; SCORE; MEAT

Background: The Mediterranean diet (MD) has been proposed as a means for cancer prevention, but little evidence has been accrued regarding its potential to prevent pancreatic cancer. We investigated the association between the adherence to the MD and

pancreatic cancer risk within the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort. Methods: Over half a million participants from 10 European countries were followed up for over 11 years, after which 865 newly diagnosed exocrine pancreatic cancer cases were identified. Adherence to the MD was estimated through an adapted score without the alcohol component (arMED) to discount alcohol-related harmful effects. Cox proportional hazards regression models, stratified by age, sex and centre, and adjusted for energy intake, body mass index, smoking status, alcohol intake and diabetes status at recruitment, were used to estimate hazard ratios (HRs) associated with pancreatic cancer and their corresponding 95% confidence intervals (CIs). Results: Adherence to the arMED score was not associated with risk of pancreatic cancer (HR high vs low adherence = 0.99; 95% CI: 0.77-1.26, and HR per increments of two units in adherence to arMED = 1.00; 95% CI: 0.94-1.06). There was no convincing evidence for heterogeneity by smoking status, body mass index, diabetes or European region. There was also no evidence of significant associations in analyses involving microscopically confirmed cases, plausible reporters of energy intake or other definitions of the MD pattern. Conclusions: A high adherence to the MD is not associated with pancreatic cancer risk in the EPIC study.

Godos, J.; Bella, F.; Sciacca, S.; Galvano, F.;
Grosso, G. Vegetarianism and breast, colorectal and
prostate cancer risk: an overview and meta-analysis of cohort
studies JOURNAL OF HUMAN NUTRITION AND DIETETICS
English Article breast
cancer; colorectal cancer; epidemiology; meta-analysis; prostate
cancer; vegetarian diet; vegetarianism LOW MEAT CONSUMPTION;
POPULATION-BASED COHORT; DIETARY PATTERNS; MEDITERRANEAN DIET;
LIFE-STYLE; HEALTH; DYSLIPIDEMIA; PREVENTION; VEGETABLES; HUMANS
BackgroundVegetarian diets may be associated with certain
benefits toward human health, although current evidence is scarce
and contrasting. In the present study, a systematic review and
meta-analysis of prospective cohort studies was performed with
respect to the association between vegetarian diets and breast,
colorectal and prostate cancer risk. MethodsStudies were
systematically searched in Pubmed and EMBASE electronic databases.
Eligible studies had a prospective design and compared vegetarian,
semi- and pesco-vegetarian diets with a non-vegetarian diet.
Random-effects models were applied to calculate relative risks
(RRs) of cancer between diets. Statistical heterogeneity and
publication bias were explored. ResultsA total of nine studies
were included in the meta-analysis. Studies were conducted on six
cohorts accounting for 686 629 individuals, and 3441, 4062 and
1935 cases of breast, colorectal and prostate cancer,
respectively. None of the analyses showed a significant
association of vegetarian diet and a lower risk of either breast,
colorectal, and prostate cancer compared to a non-vegetarian diet.
By contrast, a lower risk of colorectal cancer was associated with
a semi-vegetarian diet (RR = 0.86, 95% confidence interval = 0.79-
0.94; I-2 = 0%, P-heterogeneity = 0.82) and a pesco-vegetarian
diet (RR = 0.67, 95% confidence interval = 0.53, 0.83; I-2 = 0%,
P-heterogeneity = 0.46) compared to a non-vegetarian diet. The
subgroup analysis by cancer localisation showed no differences in
summary risk estimates between colon and rectal cancer.
ConclusionsA summary of the existing evidence from cohort studies
on vegetarian diets showed that complete exclusion of any source
of protein from the diet is not associated with further benefits
for human health. [Godos, J.; Bella, F.; Sciacca, S.; Grosso,

J Clemens, MA Clemens, Michael A.
 Global Skill Partnerships: a proposal for technical training
 in a mobile world IZA JOURNAL OF LABOR POLICY
 English Article Brain
 drain; Development; Education; Finance; Health; Nurse; Eldercare;
 Mobility; Aging; Migration BRAIN-DRAIN; PHYSICIAN ASSISTANTS;
 NURSE-PRACTITIONERS; HEALTH-CARE; WORKFORCE Skilled workers
 emigrate from developing countries in rising numbers, raising
 fears of a drain on the human and financial resources of the
 countries they leave. This paper critiques existing policy
 proposals to address the development effects of skilled migration.
 It then proposes a new kind of ex ante public-private agreement to
 link skill formation and skilled migration for the mutual benefit
 of origin countries, destination countries, and migrants: 'Global
 Skill Partnerships'. The paper describes how such an agreement
 might work in one profession (nursing) and one region (North
 Africa), and offers design lessons from related initiatives around
 the world. [Clemens, Michael A.] Ctr Global Dev, 2055 L St NW, 5th

A treelet transform analysis to relate
nutrient patterns to the risk of hormonal receptor-defined breast
cancer in the European Prospective Investigation into Cancer and
Nutrition (EPIC) PUBLIC HEALTH NUTRITION English
Article Nutrient patterns;
Treelet transform; Breast cancer; European Prospective
Investigationinto Cancer and Nutrition; Principal component
analysis TOTAL-ENERGY INTAKE; DIETARY PATTERNS; ALCOHOL-
CONSUMPTION; MEDITERRANEAN DIET; PROSPECTIVE COHORT; ASSOCIATION;
DISEASE; PROJECT; WOMEN; LIFE Objective Pattern analysis has
emerged as a tool to depict the role of multiple nutrients/foods
in relation to health outcomes. The present study aimed at
extracting nutrient patterns with respect to breast cancer (BC)
aetiology. Design Nutrient patterns were derived with treelet
transform (TT) and related to BC risk. TT was applied to twenty-
three log-transformed nutrient densities from dietary
questionnaires. Hazard ratios (HR) and 95 % confidence intervals
computed using Cox proportional hazards models quantified the
association between quintiles of nutrient pattern scores and risk
of overall BC, and by hormonal receptor and menopausal status.
Principal component analysis was applied for comparison. Setting
The European Prospective Investigation into Cancer and Nutrition
(EPIC). Subjects Women (n 334 850) from the EPIC study. Results
The first TT component (TC1) highlighted a pattern rich in
nutrients found in animal foods loading on cholesterol, protein,
retinol, vitamins B-12 and D, while the second TT component (TC2)
reflected a diet rich in -carotene, riboflavin, thiamin, vitamins
C and B-6, fibre, Fe, Ca, K, Mg, P and folate. While TC1 was not

associated with BC risk, TC2 was inversely associated with BC risk overall (HRQ5 v. Q1=089, 95 % CI 083, 095, P-trend<001) and showed a significantly lower risk in oestrogen receptor-positive (HRQ5 v. Q1=089, 95 % CI 081, 098, P-trend=002) and progesterone receptor-positive tumours (HRQ5 v. Q1=087, 95 % CI 077, 098, P-trend<001). Conclusions TT produces readily interpretable sparse components explaining similar amounts of variation as principal component analysis. Our results suggest that participants with a nutrient pattern high in micronutrients found in vegetables, fruits and cereals had a lower risk of BC.  Gonul Primary echinococcal cyst in the axillary region
 JOURNAL OF INFECTION IN DEVELOPING COUNTRIES
 English Article Hydatid
 Cyst; Breast Cancer; Axilla NEEDLE-ASPIRATION BIOPSY; PRIMARY
 HYDATID CYST; THYROID-GLAND; DISEASE Introduction: Human
 hydatid disease is a parasitic infection caused by the larval form
 of Echinococcus granulosus. It has worldwide distribution and is
 endemic in many countries, especially the Mediterranean region. It
 most commonly affects the liver and lungs although multi-organ
 involvement has been observed in 20-30% of patients. Case report:
 A 45-year-old woman presented to a gynaecologist because of a mass
 in the axillary region. Her mother and her two sisters were
 undergoing treatment for breast cancer. In her examination, a
 hard, semi-mobile, painless mass was found that was approximately
 3 cm in diameter. Axillary ultrasonography showed lymphadenopathy.
 No abnormality was found in mammographic examination of either
 breast, or in abdominal ultrasonography and chest X-ray. Occult
 breast cancer was suspected but when the mass was excised for
 pathological examination the biopsy showed a hydatid cyst with
 germinative membranes. Subsequent lung, abdomen and brain
 tomography scans, whole body bone scintigraphy and hydatid
 serology, including indirect haemagglutination and enzyme-linked
 immunosorbent assay, were negative. For these reasons an isolated
 axillary hydatid cyst was diagnosed. Conclusion: Parasitic cysts
 should be considered in endemic areas in patients presenting with
 a soft tissue mass in the axillary region. Imaging methods should
 be planned to include this possibility. [Ozsoy, Mustafa; Keles,

Importance of Nectin2, NUF2, and Nectin4 Gene Expression in the Pathogenesis of Different Subtypes of Breast Cancer
MIDDLE EAST JOURNAL OF CANCER English

Article Triple negative breast neoplasms; Biomarker; Estrogen receptor; Progesterone receptor
Background: The targeted therapy using breast cancer (BC)-associated biomarkers has significantly minimized the side-effects of BC treatment. This study aims to elucidate the role of Nectin2, NUF2, and Nectin4 gene expression in the pathogenesis of BC. Method: In this case-control study, the expression of Nectin2, Nectin4, and NUF2 genes was investigated through real-time polymerase chain reaction assay in 46 tumor tissues from BC patients and 46 adjacent non-tumorous tissues as a control group. Data were analyzed using SPSS-21 software, employing independent t-tests and one-way ANOVA. A P-value of <0.05 was considered statistically significant. Results: The results demonstrated a significant increase in the expression of the NUF2 gene in tumor tissues compared with adjacent normal tissues (P = 0.005, fold change = 3.7). No statistically significant difference was observed in the expression of Nectin2 and Nectin4 between the tumor and adjacent tissues. However, higher expression of Nectin2 was noted in the early stages of the disease, particularly in subtypes with estrogen receptor-positive (ER+), progesterone receptor positive (PR+), and human epidermal growth factor receptor 2 negative (HER2-). Furthermore, the expression of NUF2 and Nectin4 was elevated in advanced stages and triple-negative BC subtypes. Notably, the expression of these three genes was higher in patients aged ≤ 45 years. Conclusion: The findings suggest that the expression levels of NUF2, Nectin2, and Nectin4 genes may influence the initiation, progression, and pathogenesis of BC subtypes. Cardiovascular disease risk profile and management practices
 in 45 low-income and middle-income countries: A cross-sectional
 study of nationally representative individual-level survey data
 PLOS MEDICINE English Article

BLOOD-PRESSURE; STRATEGIES Author
 summary Why was this study done? CVD burden in low-income and
 middle-income countries (LMICs) is high and rising. CVD risk
 estimation using validated risk prediction equations is
 recommended in most guidelines; however, there are few population-
 representative analyses of CVD risk and its association with
 socio-demographic characteristics. Despite guidelines recommending
 using CVD risk estimates as an essential first step in guiding
 management practices, the extent to which risk-based approaches
 are being implemented in LMICs is not well characterised. What did
 the researchers do and find? We analysed population-representative
 survey data from 45 LMICs to determine country-specific levels of
 CVD risk, associations between socio-demographic factors and
 levels of CVD risk, and adherence to WHO guidelines on use of
 blood pressure medication. We found high variation in CVD risk
 profiles, with higher levels of risk in the Europe and the Eastern
 Mediterranean region and lower levels of risk in sub-Saharan
 Africa, as well as an inverse association between CVD risk and
 higher education and employment in most countries. We found an
 underuse of medicines in people at elevated CVD risk across all
 countries (only 24.2% of males and 41.6% of females at high CVD
 risk are taking guideline-recommended BP medication) and an
 overuse of medicines in people at lower levels of CVD risk, with
 47% of all BP medication being used by people at low CVD risk
 without a guideline indication for use. What do these findings
 mean? There is large variation in CVD risk across LMICs, and an
 inverse association between CVD risk and higher education and
 employment in most countries. There is an overuse of medicines in
 people at lower levels of CVD risk and an underuse of medicines in
 people at elevated CVD risk across all countries. The large
 heterogeneity of the findings in this study reflects varying

country contexts. Country-specific targeted policies are needed to improve the identification and management of those at highest CVD risk. Background Global cardiovascular disease (CVD) burden is high and rising, especially in low-income and middle-income countries (LMICs). Focussing on 45 LMICs, we aimed to determine (1) the adult population's median 10-year predicted CVD risk, including its variation within countries by socio-demographic characteristics, and (2) the prevalence of self-reported blood pressure (BP) medication use among those with and without an indication for such medication as per World Health Organization (WHO) guidelines. Methods and findings We conducted a cross-sectional analysis of nationally representative household surveys from 45 LMICs carried out between 2005 and 2017, with 32 surveys being WHO Stepwise Approach to Surveillance (STEPS) surveys. Country-specific median 10-year CVD risk was calculated using the 2019 WHO CVD Risk Chart Working Group non-laboratory-based equations. BP medication indications were based on the WHO Package of Essential Noncommunicable Disease Interventions guidelines. Regression models examined associations between CVD risk, BP medication use, and socio-demographic characteristics. Our complete case analysis included 600,484 adults from 45 countries. Median 10-year CVD risk (interquartile range [IQR]) for males and females was 2.7% (2.3%-4.2%) and 1.6% (1.3%-2.1%), respectively, with estimates indicating the lowest risk in sub-Saharan Africa and highest in Europe and the Eastern Mediterranean. Higher educational attainment and current employment were associated with lower CVD risk in most countries. Of those indicated for BP medication, the median (IQR) percentage taking medication was 24.2% (15.4%-37.2%) for males and 41.6% (23.9%-53.8%) for females. Conversely, a median (IQR) 47.1% (36.1%-58.6%) of all people taking a BP medication were not indicated for such based on CVD risk status. There was no association between BP medication use and socio-demographic characteristics in most of the 45 study countries. Study limitations include variation in country survey methods, most notably the sample age range and year of data collection, insufficient data to use the laboratory-based CVD risk equations, and an inability to determine past history of a CVD diagnosis. Conclusions This study found underuse of guideline-indicated BP medication in people with elevated CVD risk and overuse by people with lower CVD risk. Country-specific targeted policies are needed to help improve the identification and management of those at highest CVD risk. G-quadruplexes with naphthalene-diimides as RNA polymerase I
inhibitors for colorectal cancer treatment CELL CHEMICAL BIOLOGY
English Article

TRANSCRIPTION; BINDING; VISUALIZATION; TRANSPORTERS;
VITRO Guanine quadruplexes (G4s) are non-canonical nucleic acid
structures commonly found in regulatory genomic regions. G4
targeting has emerged as a therapeutic approach in cancer. We have
screened naphthalene-diimides (NDIs), a class of G4 ligands, in a
cellular model of colorectal cancer (CRC). Here, we identify the
leading compound T5 with a potent and selective inhibition of cell
growth by high-affinity binding to G4s in ribosomal DNA, impairing
RNA polymerase I (Pol I) elongation. Consequently, T5 induces a
rapid inhibition of Pol I transcription, nucleolus disruption,
proteasome-dependent Pol I catalytic subunit A degradation and
autophagy. Moreover, we attribute the higher selectivity of
carbohydrate-conjugated T5 for tumoral cells to its preferential
uptake through the overexpressed glucose transporter 1. Finally,

we succinctly demonstrate that T5 could be explored as a therapeutic agent in a patient cohort with CRC. Therefore, we report a mode of action for these NDIs involving ribosomal G4 targeting.  Fluid Extracted from the Sea Cucumber *Holothuria tubulosa* against
 Triple-Negative MDA-MB231 Breast Cancer Cells BIOLOGY-BASEL
 English Article

Holothuria tubulosa; coelomic fluid; breast cancer; cell
 viability; cell cycle; mitochondrial function; autophagyIN-VITRO;
 AUTOPHAGY; ANTICANCER; LINES; INHIBITOR; APOPTOSIS; CAPACITY;
 BECLIN-1; KINASE; DEATH Growing evidence has demonstrated that
 the extracts of different holothurian species exert beneficial
 effects on human health. Triple negative breast cancers (TNBC) are
 highly malignant tumors that present a poor prognosis due to the
 lack of effective targeted therapies. In the attempt to identify
 novel compounds that might counteract TNBC cell growth, we studied
 the effect of the exposure of the TNBC cell line MDA-MB231 to
 total and filtered aqueous extracts of the coelomic fluid obtained
 from the sea cucumber *Holoturia tubulosa*, a widespread species in
 the Mediterranean Sea. In particular, we examined cell viability
 and proliferative behaviour, cell cycle distribution, apoptosis,
 autophagy, and mitochondrial metabolic/cell redox state. The
 results obtained indicate that both total and fractionated
 extracts are potent inhibitors of TNBC cell viability and growth,
 acting through both an impairment of cell cycle progression and
 mitochondrial transmembrane potential and a stimulation of
 cellular autophagy, as demonstrated by the increase of the acidic
 vesicular organelles and of the intracellular protein markers
 beclin-1, and total LC3 and LC3-II upon early exposure to the
 preparations. Identification of the water-soluble bioactive
 component(s) present in the extract merit further investigation
 aiming to develop novel prevention and/or treatment agents
 efficacious against highly metastatic breast carcinomas.

Modulation of faecal miRNAs highlights the preventive effects of a Mediterranean low-inflammatory dietary intervention
CLINICAL NUTRITION English Article

Familial Adenomatous Polyposis (FAP); Mediterranean low-inflammatory; intervention diet; Stool microRNA profiles; Intestinal tissue gene expression; Small RNA sequencing
COLORECTAL-CANCER; EXPRESSION; MICRORNA; MUCOSA; SAMPLE;

PILOT; FAP Background: Dietary interventions have been proposed as therapeutic approaches for several diseases, including cancer. A low-inflammatory Mediterranean dietary intervention, conducted as a pilot study in subjects with Familial Adenomatous Polyposis (FAP), reduced markers of local and systemic inflammation. We aim to determine whether this diet may modulate faecal microRNA (miRNA) and gene expression in the gut. Methods: Changes in the faecal miRNome were evaluated by small RNA sequencing at baseline (T0), after the three-month intervention (T1), and after an additional three months (T2). Changes in the transcriptome of healthy rectal mucosa and adenomas were evaluated by RNA sequencing at T0 and T2. The identification of validated miRNA-gene interactions and functional analysis of miRNA targets were performed using in silico approaches. Results: Twenty-seven subjects were included in this study. It was observed that the diet modulated 29 faecal miRNAs ($p < 0.01$; $|\log_2 \text{Fold Change}| > 1$), and this modulation persisted for three months after the intervention. Levels of miR-3612-3p and miR-941 correlated with the adherence to the diet, miR-3670 and miR-4252-5p with faecal calprotectin, and miR-3670 and miR-6867 with serum calprotectin. Seventy genes were differentially expressed between adenoma and normal tissue, and most were different before the dietary intervention but reached similar levels after the diet. Functional enrichment analysis identified the proinflammatory ERK1/2, cell cycle regulation, and nutrient response pathways as commonly regulated by the modulated miRNAs and genes. Conclusions: Faecal

Italy(Compagnia di San Paolo); The 5 per 1000 Funds-MIUR-2014 MG and MV are supported by funds obtained through an Italian law that allows taxpayers to allocate 0.5 percent of their income tax to a research institution of their choice (5 per 1000 Funds-MIUR-2014) . screening of phenolic compounds in olive leaf extracts by
hyphenated liquid chromatography and preliminary evaluation of
cytotoxic activity against human breast cancer cells

ANALYTICAL AND BIOANALYTICAL CHEMISTRY English
Article; Proceedings Paper 36th Colloquium Spectroscopicum
Internationale AUG 30-SEP 03, 2009 Eotvos Lorand Univ,
Budapest, HUNGARY Eotvos Lorand Univ Olive leaf;
Phenolic compounds; High-performance liquid chromatography; Time-
of-flight mass spectrometry; Ion trap multiple-stage tandem mass
spectrometry; Breast cancer TANDEM MASS-SPECTROMETRY; OLEA-
EUROPAEA L.; TIME-OF-FLIGHT; MEDITERRANEAN DIET; OLEUROPEIN
AGLYCON; IDENTIFICATION; LEAVES; OIL; POLYPHENOLS; PRESSURE In
this work, high-performance liquid chromatography (HPLC) coupled
to electrospray time-of-flight mass spectrometry (ESI-TOF-MS) and
electrospray ion trap multiple-stage tandem mass spectrometry
(ESI-IT-MS(2)) has been applied to screen phenolic compounds in
olive leaf extracts. The use of a small particle size C18 column
(1.8 μ m) provided great resolution and made separation of a lot
of isomers possible. The structural characterization was based on
accurate mass data obtained by ESI-TOF-MS, and the nature of
fragmentation ions were further confirmed by ESI-IT-MS(2) when
possible. In addition, we employed tetrazolium salt (MTT)-based
assays to assess the effects of olive leaf extracts on the growth
of human tumor-derived cells. Upon this approach, we achieved an
accurate profile of olive leaf phenolics along with the
identification of several important isomers of secoiridoids and
flavonoids. This will allow a better understanding of the complete
composition of olive-leaf-bioactive compounds as well as their
involvement in Olea europaea L. biochemical pathways. Importantly,
olive leaf extracts exhibited dose-dependent inhibitory effects on
the metabolic status (cell viability) of three breast cancer
models in vitro. Since the tumoricidal activity of the extracts

should be mainly attributed to the identified olive leaf phenolics, these findings warrant further investigation at the structure-function molecular level to definitely establish the anticancer value of these phytochemicals. IDENTIFICATION; VISUALIZATION; SELECTION

Protein-protein-interaction networks (PPINs) organize fundamental biological processes, but how oncogenic mutations impact these interactions and their functions at a network-level scale is poorly understood. Here, we analyze how a common oncogenic KRAS mutation (KRAS(G13D)) affects PPIN structure and function of the Epidermal Growth Factor Receptor (EGFR) network in colorectal cancer (CRC) cells. Mapping >6000 PPIs shows that this network is extensively rewired in cells expressing transforming levels of KRAS(G13D) (mtKRAS). The factors driving PPIN rewiring are multifactorial including changes in protein expression and phosphorylation. Mathematical modelling also suggests that the binding dynamics of low and high affinity KRAS interactors contribute to rewiring. PPIN rewiring substantially alters the composition of protein complexes, signal flow, transcriptional regulation, and cellular phenotype. These changes are validated by targeted and global experimental analysis. Importantly, genetic alterations in the most extensively rewired PPIN nodes occur frequently in CRC and are prognostic of poor patient outcomes. Khoshroo, Mohammad; Yazdanpanah, Mohammad Javad; Yasrebi,
Samira Serum Interleukin-24 Levels in Gastric and
Breast Cancers and Non-cancerous Inflammations MIDDLE EAST
JOURNAL OF CANCER English Article

Interleukin- 24; Breast cancer;
Helicobacter pylori; Gastric cancer DIFFERENTIATION-ASSOCIATED
GENE; HUMAN-MELANOMA DIFFERENTIATION; IL-24 EXPRESSION; RECEPTORS;
CYTOKINE; CELLS; MDA-7/IL-24; GROWTH; MDA-7 Background: Human
interleukin-24 (IL-24) is a cytokine belonging to the Interleukin-
10 (IL-10) family of cytokines, also known as melanoma
differentiation-associated gene 7, due to its discovery as a
tumor-suppressing protein. A tumor-suppressing protein, IL-24 is
produced by a variety of cells, including cancerous and non-
cancerous healthy cells. The aim of the present study was to
evaluate serum IL-24 concentrations in different cancers and
compare them with non-cancerous inflammations. Method: In this
case-control study, we divided a total of 200 subjects into five
groups of 40 control subjects without cancer and without
Helicobacter Pylori (H. Pylori) infection, patients with gastric
cancer and H. Pylori infection, patients with H. Pylori infection
without cancer, and patients with breast cancer and without H.
Pylori infection. We measured the serum IL-24 level using specific
enzyme-linked immunosorbent assay (ELISA) kit; we analysed the
data with SPSS software. Results: The level of IL-24 was
significantly higher in breast cancer group (160.65 +/-55pg/mL)
(mean= SD) followed by gastric cancer with (76.2 +/-16.27 pg/mL)
(mean +/- SD) and without (72.5 +/- 17.84 pg/mL) (mean +/- SD) H.
Pylori infection groups. The level of IL-24 in H. Pylori infected
patients and controls were (32.78 +/- 12.96 pg/mL) (mean +/- SD)
and (27.4 +/- 8.5 pg/mL (mean +/- SD)), respectively. Conclusion:
The mechanisms by which IL-24 is produced may be different between
immune and cancer cells and serum IL-24 is more likely generated
by immune cells than tumor cells. In breast cancer patients,
estrogen or other sex hormones may provoke IL-24 production.

Background: A high number of human breast cancers overexpress the murine double minute (MDM2) gene which blocks the p53 protein which plays an important role in arresting the cell growth. The present study aimed to investigate the efficacy of siRNA specific MDM2 in knocking down MDM2 and its subsequent effects on p53 to exert antiproliferative effects on Michigan Cancer Foundation-7 (MCF-7) breast cancer cells. Method: In this in vitro study, we used the specific siRNA of the MDM2 gene to knock down the expression of the MDM2 protein in the MCF-7 cell line. The expression of MDM2, BCL2-associated X (BAX), BH3 interacting-domain death agonist (BID), and B cell lymphoma 2 (BCL2) genes was evaluated using the real-time polymerase chain reaction (PCR) technique. The apoptosis level was also assessed using the flow cytometry technique by the Annexin V test. Results: The results showed that the entry of MDM2 siRNA into MCF-7 cells significantly reduced the mRNA expression of MDM2 gene (P-value < 0.05). Besides, the expression of the antiapoptotic gene of BCL2 significantly decreased (P-value < 0.05) in transfected MCF-7 cells, while that of BAX and BID genes increased (P-value < 0.05). Conclusion: Based on the results, MDM2 inhibition is conducive to prevent cancer metastasis by the induction of cancer cell apoptosis. Moreover, it can be considered in cancer therapy along with chemotherapy.

Mediterranean Diet Influences the Fecal Metabolic Profile of
Microbial-Derived Phenolics in a Spanish Cohort of Middle-Age and
Older People JOURNAL OF AGRICULTURAL AND FOOD CHEMISTRY
English Article

Mediterranean dietary pattern; phenolic compounds; fiber;
fecal metabolites excretion; physical activity RED WINE/GRAPE
JUICE; MAJOR FOOD SOURCES; HUMAN FECES; INTESTINAL MICROBIOTA;
COLORECTAL-CANCER; BLACK TEA; POLYPHENOLS; WINE; ANTHOCYANINS;
PATTERNS Despite the evidence regarding the influence of
certain polyphenol food sources on the metabolic profile in feces,
the association between the different phenolics provided by the
diet and the fecal phenolic profile has not been elucidated. In
this study, the composition of phenolic metabolites in fecal
solutions was analyzed by UPLC-ESI-MS/MS in 74 volunteers. This
fecal phenolic profile showed a high interindividual variation of
the different compounds analyzed, phenylacetic and phenylpropionic
acids being the major classes of phenolic metabolites excreted in
feces. Subjects with higher adherence to a Mediterranean dietary
pattern presented greater fecal concentrations of benzoic and 3-
hydroxyphenylacetic acids, positively correlated with the intake
of the principal classes and subclasses of polyphenols and fibers,
and higher levels of Clostridium cluster XVIa and Faecalibacterium
prausnitzii. These results provide a link among the Mediterranean
dietary pattern, the bioactive compounds of the diet, and the
fecal metabolic phenolic profile. [Gutierrez-Diaz, Isabel;

 Zhi-Jie Differences in Incidence and Mortality
 Trends of Colorectal Cancer Worldwide Based on Sex, Age, and
 Anatomic Location CLINICAL GASTROENTEROLOGY AND HEPATOLOGY
 English Article

SEER; NORDCAN; Global; Economic Factor TEMPORAL PATTERNS;
 EUROPE BACKGROUND & AIMS: We studied incidence and mortality
 trends of colorectal cancer (CRC) in 39 countries according to
 age, sex, and anatomic location (colon vs rectum). METHODS: We
 retrieved incidence data from registries from 36 countries. The
 registries included the following: Cancer Incidence in 5
 Continents volumes I to XI; the Surveillance, Epidemiology, and
 End Results Program of the National Cancer Institute; and the
 Nordic Cancer Registries from Europe. We obtained mortality data
 from 39 countries of the World Health Organization database. We
 evaluated average annual percentage changes in CRC incidence and
 mortality in the past decade using joinpoint regression analysis.
 RESULTS: From 2007 to 2016, 2006 to 2015, or 2005 to 2014,
 depending on the availability of the data, the incidence of colon
 cancer increased in 10 of 36 countries analyzed (all in Asia or
 Europe); India had the greatest increase, followed by Poland. All
 10 of these countries have medium to high Human Development Index

(HDI) scores. Six countries had a decrease in colon cancer incidence; these countries had the highest HDI scores; the United States had the greatest decrease, followed by Israel. Seven countries (including all countries from Northern America) had a decrease in incidence among persons older than 50 years. Eight countries had an increase in colon cancer incidence among persons younger than 50 years, including the United Kingdom and India. Countries with a decreased or stable incidence among persons 50 years or older but a significant increase in persons younger than 50 years, included Germany, Australia, the United States, Sweden, Canada, and the United Kingdom. Only Italy had a decrease in CRC incidence among persons younger than 50 years. Among women, 12 of 36 countries (all from Asia and Europe) had an increase in colon cancer incidence and 7 countries had a decrease; India had the greatest increase followed by Slovenia. Five of 36 countries had an increase in incidence of rectal cancer and 8 countries had a decrease; Ecuador and Thailand had the greatest increases in incidence. The incidence of rectal cancer among persons younger than 50 years increased significantly in Finland, Australia, Canada, the United States, and The Netherlands. Four countries had an increase in the incidence of rectal cancer in women; Ecuador had the greatest increase followed by Thailand. The incidence of rectal cancer in women decreased in 8 countries. Among women younger than 50 years, rectal cancer incidence increased, despite a decrease in women older than 50 years, in Costa Rica, Slovenia, Japan, Slovakia, Canada, and the United States there was an increase in incidence, although their elder population had a stable or decreased incidence. Twenty-four countries reported a reduction in CRC mortality, including North America, Oceania, and most European countries. Nevertheless, some countries from Asia, Latin America, and Southern Europe had significant increases in CRC mortality. CONCLUSIONS: In an analysis of incidence and mortality databases from 39 countries, we found that the incidence of colon and rectal cancers has continued to increase in countries with medium to high HDI and in younger populations. Preventive strategies are needed for countries with increasing CRC and rectal cancer incidence and mortality. [Wong, Martin C. Tahmasebi, Sedigheh; Shahin, Baharak; Johari, Masoumeh Ghoddusi; Akrami, Majid; Zanguri, Vahid; Talei, Abdolrasoul; Keumarsi, Zahra; Karimaghaei, Nazanin Does Existence of Ductal Carcinoma In Situ Accompanying Invasive Ductal Carcinoma Lead to Different Clinicopathological Features and Clinical Outcome? Report of a Breast Cancer Registry MIDDLE EAST JOURNAL OF CANCER English Article

Ductal carcinoma in situ; Carcinoma; Breast; Prognosis; Survival LOCAL RECURRENCE; GENOMIC DIFFERENCES; CONSERVING SURGERY; AMERICAN SOCIETY; STAGE-I; COMPONENT; MARKERS; RISK; IRRADIATION; EXPRESSION Background: Ductal carcinoma in situ (DCIS) is widely recognized as the precursor of invasive ductal carcinoma (IDC). We aimed to compare clinicopathological characteristics and prognosis between IDC with and without coexisting DCIS stratified by biological subtypes to evaluate the clinical outcome of these two groups. Method: Data from 5814 patients with IDC (32.4) and IDC/DCIS (67.6%), who underwent surgery from December 1993 through December 2019, were retrospectively assessed. We evaluated the prognosis of IDC with coexisting DCIS in different molecular subtypes. Results: IDC/DCIS patients were younger ($P < 0.001$). They also presented with a low tumor grade and had less lymph node involvement compared with the pure IDC patients. Compared with the patients with IDC, luminal B subtype was more frequent in those with IDC/DCIS, with 19.4% versus 13.2 %; human epidermal growth factor receptor-2 enriched subtype was also more frequently observed, with 12.2 vs. 8.7%. The 5-year disease-free survival (DFS) was higher in the IDC/DCIS patients ($P = 0.036$). The survival outcomes significantly improved in the cases with a higher amount of DCIS. The presence of coexisting DCIS ($P = 0.038$), tumor size ($P < 0.001$), lymph node status ($P = 0.005$), lymph vascular invasion ($P = 0.02$), and molecular subtypes ($P < 0.001$) were found to be DFS-associated independent prognostic factors. Conclusion: DCIS along with IDC were associated with improved prognosis. The presence of DCIS may be a marker of lower aggressiveness, and could be noticed as a prognostic factor in future treatment algorithms. ATF2 loss promotes tumor invasion in colorectal cancer
cells via upregulation of cancer driver TROP2 CELLULAR AND
MOLECULAR LIFE SCIENCES English Article

De-adhesion; Migration; Intratumoral
heterogeneity; Liver metastasis; EMT; CAM model ACTIVATING
TRANSCRIPTION FACTOR-2; PROSTATE-CANCER; METASTASIS; SENSITIVITY;
MUTATIONS; BIOMARKER; SURVIVAL; JUN In cancer, the activating
transcription factor 2 (ATF2) has pleiotropic functions in
cellular responses to growth stimuli, damage, or inflammation. Due
to only limited studies, the significance of ATF2 in colorectal
cancer (CRC) is not well understood. We report that low ATF2
levels correlated with worse prognosis and tumor aggressiveness in
CRC patients. NanoString gene expression and ChIP analysis
confirmed trophoblast cell surface antigen 2 (TROP2) as a novel
inhibitory ATF2 target gene. This inverse correlation was further
observed in primary human tumor tissues. Immunostainings revealed
that high intratumoral heterogeneity for ATF2 and TROP2 expression
was sustained also in liver metastasis. Mechanistically, our in
vitro data of CRISPR/Cas9-generated ATF2 knockout (KO) clones
revealed that high TROP2 levels were critical for cell de-adhesion
and increased cell migration without triggering EMT. TROP2 was
enriched in filopodia and displaced Paxillin from adherens
junctions. In vivo imaging, micro-computer tomography, and
immunostainings verified that an ATF2(KO)/TROP2(high) status
triggered tumor invasiveness in in vivo mouse and chicken
xenograft models. In silico analysis provided direct support that
ATF2(low)/TROP2(high) expression status defined high-risk CRC
patients. Finally, our data demonstrate that ATF2 acts as a tumor
suppressor by inhibiting the cancer driver TROP2. Therapeutic
TROP2 targeting might prevent particularly the first steps in
metastasis, i.e., the de-adhesion and invasion of colon cancer
cells.

Associations Between Dietary Patterns and Longitudinal
 Quality of Life Changes in Colorectal Cancer Patients: The
 ColoCare Study NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL
 English Article

EUROPEAN-ORGANIZATION; MEDITERRANEAN DIET; FECAL INCONTINENCE; STYLE FACTORS; POPULATION; NUTRITION; DIAGNOSIS; SURVIVAL; FIBER; IMPACT

Quality of life (QoL) is an important clinical outcome in cancer patients. We investigated associations between dietary patterns and QoL changes in colorectal cancer (CRC) patients. The study included 192 CRC patients with available EORTC QLQ-C30 data before and 12 months post-surgery and food frequency questionnaire data at 12 months post-surgery. Principal component analysis was used to identify dietary patterns. Multivariate regression models assessed associations between dietary patterns and QoL changes over time. We identified four major dietary patterns: "Western" dietary pattern characterized by high consumption of potatoes, red and processed meat, poultry, and cakes, "fruit& vegetable" pattern: high intake of vegetables, fruits, vegetable oils, and soy products, "bread& butter" pattern: high intake of bread, butter and margarine, and "high-carb" pattern: high consumption of pasta, grains, nonalcoholic beverages, sauces and condiments. Patients following a "Western" diet had lower chances to improve in physical functioning (OR = 0.45 [0.21-0.99]), constipation (OR = 0.30 [0.13-0.72]) and diarrhea (OR: 0.44 [0.20-0.98]) over time. Patients following a "fruit& vegetable" diet showed improving diarrhea scores (OR: 2.52 [1.21-5.34]). A "Western" dietary pattern after surgery is inversely associated with QoL in CRC patients, whereas a diet rich in fruits and vegetables may be beneficial for patients' QoL over time. BLACK-RASPBERRY EXTRACT; RUBUS-ALCEIFOLIUS POIR; XENOBIOTIC-METABOLIZING ENZYMES; COLONIC ADENOMA DEVELOPMENT; RANDOMIZED CONTROLLED-TRIAL; TO-MESENCHYMAL TRANSITION; CELLS IN-VITRO; VIRGIN OLIVE; BREAST-CANCER; BLOOD-PRESSURE

The traditional Mediterranean diet (MedDiet) is a well-known dietary pattern associated with longevity and improvement of life quality as it reduces the risk of the most common chronic pathologies, such as cancer and cardiovascular diseases (CVDs), that represent the principal cause of death worldwide. One of the most characteristic foods of MedDiet is olive oil, a very complex matrix, which constitutes the main source of fats and is used in the preparation of foods, both raw as an ingredient in recipes, and in cooking. Similarly, strawberries and raspberries are tasty and powerful foods which are commonly consumed in the Mediterranean area in fresh and processed forms and have attracted the scientific and consumer attention worldwide for their beneficial properties for human health. Besides olive oil and berries, honey has lately been introduced in the MedDiet thanks to its relevant nutritional, phytochemical and antioxidant profile. It is a sweet substance that has recently been classified as a functional food. The aim of this review is to present and discuss the recent evidence, obtained from in vitro, in vivo and epidemiological studies, on the potential roles exerted by these foods in the prevention and progression of different types of cancer and CVDs. RADIOMICS; FEATURES; SCALE Colorectal cancer (CRC) constitutes the third most commonly diagnosed cancer in males and the second in females. Precise histopathological classification of CRC tissue pathology is the cornerstone not only for diagnosis but also for patients' management decision making. An automated system able to accurately classify different CRC tissue regions may increase diagnostic precision and alleviate clinical workload. However, tissue classification is a challenging task due to the variability in morphological and textural characteristics present in histopathology images. In this study, an artificial neural network was trained to classify between eight classes of CRC tissue image patches derived from a public dataset with 5000 CRC histopathology image tiles. A total of 532 multi-level pathomics features examined at different scales were extracted by visual descriptors such as local binary patterns, wavelet transforms and Gabor filters. An exhaustive evaluation involving a variety of wavelet families and parameters was performed in order to shed light on the impact of scale on pathomics based CRC tissue differentiation. Our model achieved a performance accuracy of 95.3% with tenfold cross validation demonstrating superior performance compared to 87.4% reported in recent studies. Furthermore, we experimentally showed that the

first and the second levels of the wavelet approximations can be used without compromising classification performance.

J Santella, ME; Hagedorn, RL; Wattick, RA; Barr, ML; Horacek, TM; Olfert, MD Santella, Madison E.; Hagedorn, Rebecca L.; Wattick, Rachel A.; Barr, Makenzie L.; Horacek, Tanya M.; Olfert, Melissa D. Learn first, practice second

approach to increase health professionals' nutrition-related knowledge, attitudes and self-efficacy INTERNATIONAL JOURNAL OF FOOD SCIENCES AND NUTRITION English Article

Mediterranean Diet; nutrition education; self-efficacy; attitude; experiential learning

EDUCATION INTERVENTION; MEDITERRANEAN DIET; LOW-INCOME; STUDENTS; QUALITY; MODEL Health professionals generally have positive attitudes towards the role of nutrition in medicine, but limited knowledge and low self-efficacy for incorporating it into routine care. To assess the effectiveness of a "learn first, practice second" intervention on the nutrition-related knowledge, attitudes, and self-efficacy of multidisciplinary health professionals, the present approach consisted of 16 weeks of online

education and 2 weeks of cultural immersion in Tuscany, Italy. Data was captured via online surveys at Baseline, Post-education, Post-immersion, and Follow Up. Repeated measures ANOVA with irregular spacing was used, followed by Dunnett's or Cochran-Mantel-Haenszel testing. Results indicate significantly improved participant nutrition knowledge (nonzero correlation $p=.0136$, means score $p=.0075$) and self-efficacy (T0-T1 $p<.0001$, T0-T2 $p<.0001$, T0-T3 $p=.0002$), with differences in attitude trending towards significance ($p=.0764$). Findings from this study suggest that a combination of online education and hands on learning experiences can be beneficial for increasing health professionals' nutrition knowledge, confidence, and potentially attitude. Relationship between international remittances, political
stability and income inequality: evidence from MENA countries
JOURNAL OF ECONOMIC AND ADMINISTRATIVE SCIENCES
English Article; Early Access
Income inequality; Remittances; MENA; Political stability;

Pooled mean group; Granger non-causality; D31; O53; P16; C33; F24
ECONOMIC-GROWTH; TRADE LIBERALIZATION; MIGRATION; POVERTY;
CHALLENGES; LINKAGES; IMPACT; PANEL PurposeDespite the
significant role of remittances in the Middle East and North
Africa (MENA) region, their impact on income inequality has
received limited attention in related research, especially in
times of political instability. Therefore, this paper explores the
moderating effect of political stability on the strengthening of
the relationship between remittance inflows and income inequality
in MENA countries over the period 1996-
2022.Design/methodology/approachThis paper utilizes the pooled
mean group (PMG) approach. For robustness, Dumitrescu and Hurlin's
(2012) panel Granger non-causality test has been conducted,
revealing the absence of reverse causality.FindingsThis paper
demonstrates that remittance inflows increase income inequality in
MENA recipient countries, indicating that most individuals
receiving remittances in the MENA region are predominantly from
well-off families. In addition, political stability reduces income
inequality in MENA recipient countries, while remittance inflows
increase income inequality when the polity becomes less
stable.Practical implicationsWe recommend addressing obstacles
faced by low-income groups seeking migration, especially in
countries with high unemployment rates, such as deficiencies in
education, skills, information asymmetry and financial
constraints. Additionally, supplementary policies, such as
directing resources toward pro-poor projects, particularly those
that improve education, health and infrastructure, should be
implemented to mitigate the adverse effects of remittances on
income distribution. Finally, priority must be given to policies
that promote political stability to create a business environment
conducive to human and physical investments.Originality/valueThe
paper addresses the impact of remittances on income inequality in
the MENA region, which has received limited attention in previous
research. [Elorabi, Khaled; Maher, Mohamed] Mansoura Univ, Dept

Effects of Valproic Acid on Cell Viability of Breast Cancer and

Genotoxicity; MTT assay; Micronucleus assay

Introduction:

Breast cancer is a complicated and multifactor disease in which so many genetic and environment agents play important roles. Nowadays different ways are available for cancer therapy such as surgery, chemotherapy and radiotherapy that are very costly and have various side effects. Valproic acid is an inhibitor of histone deacetylase enzyme that is effective on apoptosis of some cancerous cells. Aim: The aim of this research is to evaluate the toxic effects of this drug on both normal and cancerous cells, alongside with causing genetic disorder on peripheral blood lymphocytes as a model to evaluate genetic disorder. Material and methods: Cells were incubated with different concentrations of valproic acid and cisplatin. This incubation lead to cytotoxicity and Geno toxicity and then the viability of cells were measured. Cellular viability as well as Geno toxicity was assessed by MTT assay and micronucleus assay. Results: Results shows that valproic acid has an ability to significantly reduce the viability of breast cancer cells. Also toxic doses of valproic acid can affect BEAS-2B cells and can detract the viability of cells. Conclusion: This research proves the efficacy of valproic acid on cellular activity of Mcf-7 cell line and BEAS-2B cell line. This effect is probably associated with the ability of valproic acid to inhibit histone deacetylase enzyme and stop cells from growing and specialization and cause death in tumor cells, and the advantage of these drug class is that they have minimum effect on normal cells so they kill them rarely. suppress tumor growth by triggering mitochondrial dysfunction and
activation of the intrinsic apoptotic pathway in colorectal cancer
cells BIOCHEMICAL PHARMACOLOGY English Article

Nitroalkene; Nitrooleate;

Apoptosis; Cancer; ROS; Michael acceptor BOVINE SERUM-ALBUMIN;
NITROLINOLEIC ACID; MEDITERRANEAN DIET; OXIDATIVE STRESS; COLON-

CANCER; ANTITUMOR-ACTIVITY; MURINE MODEL; DNA-DAMAGE; PPAR-GAMMA; COMPLEX II Nitro-fatty acids (NFAs) are endogenously occurring lipid mediators exerting strong anti-inflammatory effects and acting as anti-oxidants in a number of animal models of inflammation. These NFA effects are mediated by targeting important regulatory proteins involved in inflammatory processes, such as 5-lipoxygenase, soluble epoxide hydrolase, or NF-kappa B. In the present study, we investigated the anti-tumorigenic effects of NFAs on colorectal cancer (CRC) cells in cell culture-based experiments and in a murine xenograft model of human CRC. We could show that 9-NOA suppresses the viability of CRC cells (HCT-116 and HT-29) by inducing a caspase-dependent apoptosis via the intrinsic apoptotic pathway. Co-treatment with the pan-caspase inhibitor Q-VD-OPH counteracted the NFA-mediated apoptosis in both cell lines. Furthermore, NFAs affected the cell cycle transition and reduced the oxygen consumption rate (OCR) immediately. On the contrary to their well-known anti-oxidative properties, NFAs mediated the generation of mitochondrial oxidative stress in human CRC cells. Additionally, similar to the cytostatic drug mitomycin, 9-NOA significantly reduced tumor growth in a murine xenograft model of human colorectal cancer. In contrast to the established cytostatic drug, 9-NOA treatment was well tolerated by mice. This study delivers a novel mechanistic approach for nitro-fatty acid-induced inhibition of CRC cell growth by targeting mitochondrial functions such as the mitochondria] membrane potential and mitochondria] respiration. We suggest these naturally occurring lipid mediators as a new class of well tolerated chemotherapeutic drug candidates for treatment of CRC or potentially other inflammation-driven cancer types.

Synergistic Anti-Breast-Cancer Effects of Combined Treatment With Oleuropein and Doxorubicin In Vivo ALTERNATIVE THERAPIES IN HEALTH AND MEDICINE English Article

NF-KAPPA-B; MEDITERRANEAN DIET; CYCLIN D1; OLIVE OIL; PATHWAY; ACTIVATION; APOPTOSIS; HYDROXYTYROSOL; CYTOSKELETON; ANTIOXIDANT Context. Breast cancer is a leading cause of cancer fatalities among women worldwide. Of the more than 80% of patients who receive adjuvant chemotherapy, approximately 40% relapse. The majority of these patients die of disseminated metastatic disease, which emphasizes the need for new therapeutic strategies Objective. The study intended to investigate the anticancer effects of oleuropein (OL) and doxorubicin (DOX) individually and in combination on breast tumor xenografts and also to evaluate the molecular pathways involved. Design. The research team designed in vivo (animal) and in vitro (cell culture) studies. Setting: The study was performed in the College of Science of King Saud University in the University Center for Women Students (Riyadh, Saudi Arabia). Animals. The study involved 40 female, nude mice (BALB/c OlaHsd-foxn1). Intervention. The mice were injected subcutaneously with MDA- MB- 231 human breast cancer cells. After the growth of tumors, the animals were randomly divided into 4 groups to receive intraperitoneal injections: (1) group 1 (control group)-dimethyl sulfoxide, (2) group 2 (intervention group)-50 mg/kg of OL, (3) group 3 (intervention group)-2.5 mg/kg of DOX, and (4) group 4 (intervention group)-1.5 mg/kg of DOX, immediately followed by 50 mg/kg of OL. The OL was extracted from Manzanillo olive trees (Olea europaea) grown in Tabouk, Saudi Arabia. Outcome Measures. The measures included the isolation and primary culture of the tumor xenografts, apoptosis analysis by annexin V, cellular

lysate preparation, and immunoblotting. Results: The volume of the tumor increased aggressively, reaching 173 mm³ in the control animals in a time-dependent manner. On the other hand, a sharp drop, to 48.7 mm³, in the volume of the tumor was observed with the 2 drugs combined, a more than 3-fold decrease. The effect was mediated through the induction of apoptosis via the mitochondrial pathway. The combined treatment downregulated the antiapoptosis and proliferation protein, nuclear factor-kappa B, and its main oncogenic target cyclin D1. Furthermore, it inhibited the expression of BCL-2 and survivin. This inhibition could explain the cooperative suppression of the proliferation of breast tumor xenografts and the induction of apoptosis by the combined effect of the compounds used. Conclusions. The key findings clearly indicate the synergistic efficacy of DOX with natural and nontoxic OL against breast tumor xenografts. [Elamin, Maha H.;

J Menendez, JA; Papadimitropoulou, A; Vellon, L; Lupu, R
Menendez, Javier A.; Papadimitropoulou, Adriana; Vellon, Luciano; Lupu, Ruth A genomic explanation connecting "Mediterranean diet", olive oil and cancer:: Oleic acid, the main monounsaturated fatty acid of olive oil, induces formation of inhibitory "PEA3 transcription factor-PEA3 DNA binding site" complexes at the Her-2/neu (erbB-2) oncogene promoter in breast, ovarian and stomach cancer cells EUROPEAN JOURNAL OF CANCER English Article

her-2/neu; erbB-2; PEA3; oleic acid; olive oil; Mediterranean diet; cancer GROWTH-FACTOR RECEPTOR; METASTATIC BREAST; MONOCLONAL-ANTIBODY; MAMMARY-CARCINOMA; NEU ONCOGENE; OVEREXPRESSION; RISK; TRASTUZUMAB; THERAPY; EXPRESSION
Olive oil is an integral ingredient of the "Mediterranean

diet" and accumulating evidence suggests that it may have a potential role in lowering risk of several cancers. We recently hypothesized that the anti-cancer actions of olive oil may relate to its monounsaturated fatty acid (MUFA) oleic acid (OA; 18:1n - 9) content to specifically regulate oncogenes. In this study, transient transfection experiments with human Her-2/neu promoter-driven luciferase gene established the ability of OA to specifically repress the transcriptional activity of Her-2/neu gene. Gene repression was seen in tumour-derived cell lines with Her-2/neu gene ;amplification and overexpression, including SK-Br3 (<= 56% reduction), SK-OV3 (<= 75% reduction) and NCI-N87 (55 reduction) breast, ovarian and stomach cancer cell lines, respectively. Also marginal decreases in promoter activity were observed in cancer cells expressing physiological levels of Her-2/neu (<= 20% reduction in MCF-7 breast cancer cells). Remarkably, OA treatment in Her-2/neu-overexpressing cancer cells was found to induce up-regulation of the Ets protein polyomavirus enhancer activator 3 (PEAS), a transcriptional repressor of Her-2/neu promoter. Also, an intact PEAS DNA-binding-site at endogenous Her-2/neu gene promoter was essential for OA-induced repression of this gene. Moreover, OA treatment failed to decrease Her-2/neu protein levels in MCF-7/Her2-18 transfectants, which stably express full-length human Her-2/neu cDNA controlled by a SV40 viral promoter. OA-induced transcriptional repression of Her-2/neu through the action of PEAS protein at the promoter level may represent a novel mechanism linking "Mediterranean diet" and cancer. Mansoorreh Down-regulation of vascular endothelial

growth factor expression by anti-her2/neu single chain antibodies

MEDICAL ONCOLOGY English Article

Single-chain antibody; HER2/neu; VEGF;

Angiogenesis; Breast cancer BREAST-CANCER; 1ST-LINE TREATMENT;

MONOCLONAL-ANTIBODIES; TUMOR ANGIOGENESIS; FACTOR VEGF; IN-VITRO;

THERAPY; CELLS; HER2; TRASTUZUMAB HER-2/neu is overexpressed in 25-30% of breast tumors. Signaling through HER-2/neu leads to an increase in the production of vascular endothelial growth factor (VEGF) and enhances angiogenesis. We evaluated the effects of three specific anti-HER2/neu single chain-Fv (scFv) antibodies on the expression level of VEGF in HER2/neu-expressing breast cancer cell lines. A nonimmunized human scFv library was panned against three epitopes of HER2/neu. BT-474 human breast cancer cell line was treated with three specific anti-HER2/neu scFv antibodies and the amount of VEGF gene transcript was determined by quantitative real-time PCR. The expression of VEGF protein was analyzed by western blot. All three scFv antibodies along with their combination inhibited VEGF expression at both the gene and protein levels. Our results show that anti-HER2/neu recombinant antibodies can be considered as anti-angiogenic agents in HER2/neu-positive breast cancers. Antibody Responses to NY-ESO-1 in Primary Breast Cancer Identify a Subtype Target for Immunotherapy
PLOS ONE English Article

TESTIS ANTIGEN NY-ESO-1; IMMUNE-RESPONSES; EXPRESSION; MELANOMA; EPITOPES; CELLS The highly immunogenic human tumor antigen NY-ESO-1 (ESO) is a target of choice for anti-cancer immune therapy. In this study, we assessed spontaneous antibody (Ab) responses to ESO in a large cohort of patients with primary breast cancer (BC) and addressed the correlation between the presence of anti-ESO Ab, the expression of ESO in the tumors and their characteristics. We found detectable Ab responses to ESO in 1% of the patients. Tumors from patients with circulating Ab to

ESO exhibited common characteristics, being mainly hormone receptor (HR)(-) invasive ductal carcinomas of high grade, including both HER2(-) and HER2(+) tumors. In line with these results, we detected ESO expression in 20% of primary HR(-) BC, including both ESO Ab(+) and Ab(-) patients, but not in HR(+) BC. Interestingly, whereas expression levels in ESO(+) BC were not significantly different between ESO Ab(+) and Ab(-) patients, the former had, in average, significantly higher numbers of tumor-infiltrated lymph nodes, indicating that lymph node invasion may be required for the development of spontaneous anti-tumor immune responses. Thus, the presence of ESO Ab identifies a tumor subtype of HR(-) (HER2(-) or HER2(+)) primary BC with frequent ESO expression and, together with the assessment of antigen expression in the tumor, may be instrumental for the selection of patients for whom ESO-based immunotherapy may complement standard therapy.

Representative Study of Deaths of North Indian Migrants and Its
Medical Certification Across the World JOURNAL OF IMMIGRANT AND
MINORITY HEALTH English Article

International migrant; Manner of death; Mode of death; Ambiguous with unspecified etiology; Medical certification of death; 2nd autopsy Many Indians is moving to other nations of the world in the search of employment, education or other reasons. The process of globalization along with the faster mode of traveling and communication has facilitated this movement in the hope of getting more opportunities and earning of easy money abroad, than in India. Unfortunately, sometimes they meet a tragic end and their families in India get only their dead bodies back from abroad. This study focuses on these kind of unfortunate tragic events faced by Indians in different countries and thereby raise a concern on their safety abroad and necessitate the need of relooking in to the quality of medical certification of death and medico legal investigations to find out the real reasons of deaths to avoid any kind of doubt in mind. Data was collected from medical death certificates and passports of the deceased Indians. There was a total of 711 dead bodies/human remains received in 2012 at IGI airport New Delhi. The Middle East countries together contributed a total of 398 (55.98 %) cases. The distribution as per manner of death shows that in maximum number of cases (269), the manner of death was ambiguous with unspecified aetiology. The study therefore recommends for upgradation of the level of medico legal investigations in form of 2nd autopsy in recipient country and proper medical death certification. Metin Bioevaluation of Spiro N-Propargylic β -Enaminones
as Anti-Breast Cancer Agents: In Vitro and Molecular Docking
Studies CHEMISTRY & BIODIVERSITY English
Article spiro N-propargylic
beta-enaminones; cytotoxicity; apoptosis; cell cycle; ADMET;
docking FLUORINE; RECEPTOR The study aimed to investigate
the in vitro inhibitory activities of spiro N-propargylic beta-
enaminones, SPEs 1-31, against BCa cells, to perform in silico
molecular docking studies to understand the nature of the
interaction between the compounds and the ER alpha, PR, EGFR, and
Her2, and to determine the ADMET and drug-likeness properties.
Cytotoxic activity was investigated via MTT assay. DNA
fragmentation was evaluated via ELISA assay. Cell cycle
distributions were investigated by flow cytometry. Expression
levels of Bcl-2, Bax, p21 and Cyclin D1 were measured by qRT-PCR
and western blot analysis. Molecular docking was done using
Autodock/vina software. ADMET analysis was calculated using the
ADMETlab 2.0 tool. SPEs 1, 22, and 28 showed selective cytotoxic
activity against all BCa cells with SI values >2. SPEs induced
apoptosis and caused significant changes in Bcl-2 and Bax levels.
The cell cycle was arrested at the S phase and levels of p21 and
Cyclin D1 were induced in all BCa cells. Molecular docking
analysis revealed that SPE1, SPE22, and SPE28 showed high binding
affinities with ER alpha, PR, EGFR, and Her2. ADMET analysis
revealed that SPEs are drug-like compounds as they obey the five
rules of Lipinsky and are not toxic. Therefore, these potential
anticancer compounds should be further validated by in vivo
studies for their appropriate function in human health with a
safety profile, and a comprehensive drug interaction study should
be performed. [Atmaca, Harika; Ilhan, Suleyman] Manisa Celal

Ali, Abuzer; Ali, Amena; Warsi, Musarrat Husain;
Ahmad, Wasim; Tahir, Abu Chemical characterization,
antidiabetic and anticancer activities of Santolina
chamaecyparissus SAUDI JOURNAL OF BIOLOGICAL SCIENCES
English Article Santolina
chamaecyparissus; Diabetes; alpha-glucosidase; EGFR; Human breast
cancer; GC-MS MEDICINAL-PLANTS; NATURAL-PRODUCTS; ESSENTIAL
OIL; DRUGS Santolina chamaecyparissus is an important medicinal
plant growing in the Mediterranean region and has been reported as
a potent anti-inflammatory, antibacterial, antioxidant, and
antifungal agent. The purpose of the current research is to
identify the chemical constituents in ethyl acetate extract (EAE)
from the leaves of *S. chamaecyparissus*, and to evaluate
antidiabetic, and anticancer activity. Chemical constituents of
EAE were identified by GC-MS, and the antidiabetic activity was
evaluated by aglucosidase inhibition assay. The anticancer
activity was assessed by Epidermal Growth Factor Receptor (EGFR)
expression in human breast cancer cell line (MCF7) by using
quantitative RT-PCR method. GC-MS analysis of EAE of *S.*
chamaecyparissus yielded 44 compounds. Tetrapentacontane (27.15%),
eicosyl acetate (8.40%), 2-methylhexacosane (6.87%), and n-
pentadecanol (5.44%) were found as major chemical constituents.
The EAE of *S. chamaecyparissus* showed concentration dependant
inhibition of alpha-glucosidase enzyme and the IC50 value (IC50
110 +/- 4.25 mu g/mL) was found comparable with standard acarbose
(IC50 105 +/- 3.74 mu g/mL). The real-time qRT-PCR results showed
that the EGFR protein (bcl-2) in human breast cancer cell line
(MCF7) was negatively expressed with a value of -0.69297105 after
treatment with EAE (100 mu g/mL). The study results are suggesting
the possible use of *S. chamaecyparissus* in the management of
diabetes, and human breast cancer. (C) 2021 The Author(s).

 levels of genes related to microtubule organization, tumor
 suppression, apoptosis, cell cycle, and proliferation were
 examined by quantitative real-time polymerase chain reaction.
 Molecular docking against Bcl-2 was carried out using AutoDock
 Vina, while ADME studies were performed to predict the
 physicochemical and drug-likeness properties of the synthesized
 compounds. The results revealed that compounds 23 and 27 were the
 most potent cytotoxic derivatives against MCF-7 cells. Gene
 expression analysis showed that BCL-2 was the most prominent gene
 studied. Treatment of MCF-7 cells with compounds 23 and 27
 resulted in significant downregulation of the BCL-2 gene, with
 fold changes of 128 and 256, respectively. Docking analysis
 predicted a strong interaction between the compounds and the
 target protein. Interestingly, all of the compounds exhibit a
 higher binding affinity toward Bcl-2 than the standard drug
 (compound 27 vina score = -9.6 kcal/mol, vincristine = -6.7
 kcal/mol). Molecular dynamics simulations of compounds 23 and 27
 showed a permanent stabilization in the binding site of Bcl-2 for
 200 ns. Based on Lipinski and Veber's filters, all synthesized
 compounds displayed drug-like characteristics. These findings
 suggest that compounds 23 and 27 were the most promising cytotoxic
 compounds and downregulated the expression of the BCL-2 gene.
 These derivatives could be further explored as potential
 candidates for the treatment of breast cancer. [Abbade, Yemna;

genetic result disclosure for women with Breast Cancer: influence
of +/-predisposition genetic mutation MEDITERRANEAN JOURNAL OF
CLINICAL PSYCHOLOGY English Article

BRCA+/-; Psychological distress;

Personality traits; Genetic testing; Psychological counseling;
Breast cancer; Oncological clinical practice; Personalized
medicine; Clinical psychology ITALIAN VERSION; PSYCHOMETRIC
PROPERTIES; EMOTION-REGULATION; IMPACT; RISK; DISTRESS; OUTCOMES;
SURGERY; STRESS Background: Albeit the genetic testing/counseling
is increasing progressively in oncological clinical practice,
psychological impact of BRCA genetic testing has been an under-
researched area in oncological population; few studies have
examined a wide range of possible predictive individual factors
for psychological adaptation after genetic testing for hereditary
cancer. Aim of the study was to examine the implication of
clinical psychological in BRCA genetic result post- disclosure
dealing with the emotional health of patients undergoing genetic
testing depending to the personal resources. Methods: Participants
were composed of n = 32 female patients in range age 30 - 55
years, who have a BC diagnosis and who underwent BRCA mutation
testing. Psychological battery was applied after genetic testing.
Results: Our finding highlighted the psychological influence of
genetic testing on wellbeing of BC patients, and more drawing
clinical perspective for positive/negative disclosure regarding
the predictors for psychological distress. Conclusion: Genetic
testing needs to be integrated by psychological counseling to
manage better the impact of result disclosure (whatever the
outcome is) in order to manage better the physical and mental
health of patients into efficient personalized medicine toward to
the improvement of patient compliance and adherence into well-
being perspective and Quality of Life maintaining. Sample size and

lack of longitudinal data could be limits of the study. Article INVASIVE

CERVICAL-CANCER; HUMAN-PAPILLOMAVIRUS; RISK; INFECTION; PARITY

Background: The cervical cancer screening coverage in Bahrain was 43.1% in 2018. Even with the presence of a screening program, most screening in the Middle East usually take place at random. Objective: To evaluate the risk factors and outcome of randomly selected smear tests. Design: A Retrospective Study. Setting: Bahrain Defence Force Hospital, Bahrain. Method: All Pap smear tests performed from January 2017 to December 2017 were included in the study. The smear results were divided into four groups: normal, borderline, premalignant changes and malignant changes. Risk factors such as age, parity, contraceptive/medical history, smoking, and human papillomavirus (HPV) positive screening were documented. The outcome of care were divided into four categories: repeat smear test, colposcopy and cervical biopsy, hysteroscopy/dilatation and curettage, and hysterectomy. Result: A total of 2,626 smear tests were included in the study; 2,246 (85.5%) were negative smears. Two hundred forty (9%) were borderline and 135 (5%) had pre-cancerous lesions. Five (0.2%) cases were malignant; the older the patient, the higher the risk of malignant changes. Twenty-nine (1.1%) of the previous pre-cancerous smear became negative on the successive smear and 72 (2.7%) patients had repeat smear test. Some of the negative and borderline patients had a hysterectomy. Conclusion: A uniform cervical screening policy must be initiated and cost-effective clear protocols must be laid down to improve the quality of women's health in Bahrain. Diet quality and nutrient

density in subjects with metabolic syndrome: Influence of socioeconomic status and lifestyle factors. A cross-sectional assessment in the PREDIMED-Plus study

CLINICAL NUTRITION

English Article

Diet

quality; Nutrient density; Mediterranean diet; Socioeconomic factors; Lifestyle factors; Metabolic syndrome

PHYSICAL-ACTIVITY QUESTIONNAIRE; DWELLING OLDER-ADULTS; MEDITERRANEAN DIET; ENERGY-INTAKE; HEALTH; POPULATION; VALIDATION; PREVENTION; PATTERNS; ADEQUACY

Background: Socioeconomic disparities and lifestyle factors are likely to determine the overall quality of the diet. In addition, overeating is compatible with inadequate micronutrient intake and it can lead to adverse health outcomes. Objective: To assess adequacy of dietary nutrient intake and to investigate the influence of socioeconomic and lifestyle factors on nutrient density in a large primary cardiovascular prevention trial conducted in healthy participants with metabolic syndrome (MetS) to assess the cardiovascular effects of an energy-restricted Mediterranean diet (PREDIMED-Plus). Methods: Baseline cross-sectional analysis of the PREDIMED-Plus trial with 6646 Spanish participants (aged 55-75 years in men and 60-75 years in women) with overweight/obesity and MetS. Energy and nutrient intake (for 10 nutrients) were calculated using a validated 143-item Food Frequency Questionnaire (FFQ) and nutrient density was estimated dividing the absolute nutrient intake by total energy intake. The prevalence of inadequate intake was estimated according to dietary reference intakes. Multivariable linear regression models were fitted to examine associations between socioeconomic status or lifestyle factors and nutrient density. Results: A considerable proportion of the screened participants showed a deficient intake of vitamins A, D, E, B-9, calcium, magnesium and dietary fibre. Inadequate intake of four or more of the ten nutrients considered was present in 17% of participants. A

higher nutrient density was directly and significantly associated with female sex, higher educational level and a better adherence to the Mediterranean diet. Lifestyle factors such as non-smoking and avoidance of sedentary lifestyles were also independently associated with better nutrient density. Conclusions: Patients with MetS, despite being overweight, exhibited suboptimal nutrient intake, especially among men. Low nutrient density diet can be largely explained by differences in socioeconomic and lifestyle factors. These results highlight the importance of focussing on nutritional education in vulnerable populations, taking into account nutrient requirements. XRCC1 and hOGG1 Genes and Risk of Nasopharyngeal Carcinoma in North African Countries MOLECULAR CARCINOGENESIS
English Article

nasopharyngeal carcinoma; DNA repair; XRCC1; hOGG1; North Africa LUNG-CANCER RISK; DNA-REPAIR GENE; GENOME-WIDE ASSOCIATION; BREAST-CANCER; SER326CYS POLYMORPHISM; SUSCEPTIBILITY; POPULATION; METAANALYSIS Although genetic susceptibility to nasopharyngeal carcinoma (NPC) has been recognized for a long time, little is known about the responsible genes. X-Ray repair cross-complementing protein 1 (XRCC1) and

human 8-oxo-guanine glycosylase 1 (hOGG1) genes are involved in deoxyribonucleic acid (DNA) repair and were found associated with NPC risk in three Asian case-control studies. The objective of the present study was to test these genes in a sample from North Africa, one of the major NPC endemic regions in the world. Three single nucleotide polymorphisms (SNPs) in the XRCC1 gene and one SNP in the hOGG1 gene were genotyped in 598 NPC cases from Morocco, Algeria, and Tunisia and 545 controls frequency matched by recruitment center, age, sex, and urban/rural household. The genotype and allelic distributions for the hOGG1 (326)Ser/Cys SNP and for the XRCC1 (399)Arg/Trp, (280)Arg/His, and (194)Arg/Trp SNPs did not differ significantly among NPC cases and controls. The XRCC1 (194)Trp allele frequency was significantly lower in the North African population than in Asian population ($f = 0.04$ vs. 0.31 in Cantonese Chinese and 0.21 Han Chinese). The hOGG1 (326)Ser allele frequency was significantly higher in the North African population ($f = 0.73$) than in Asian populations ($f = 0.39$ in Taiwanese). The results of the present study obtained from a large sample indicate that the XRCC1 and hOGG1 genes are unlikely to play a role in the susceptibility to NPC in North Africans. Our results do not corroborate those found in Asian population on smaller samples. (C) 2011 Wiley-Liss, Inc.  Vitamin D and health in the Mediterranean countries
 HORMONES-INTERNATIONAL JOURNAL OF ENDOCRINOLOGY AND
 METABOLISM English Article; Proceedings Paper 1st
 Mediterranean Expert Meeting on Vitamin D in the Prevention of
 Health Disparities during Adult Life SEP 29, 2017
 Thessaloniki, GREECE Vitamin D; Autism; Cancer;
 Cardiovascular disease; Dental caries; Respiratory tract
 infections; All-cause mortality; Pregnancy and birth outcomes
 SERUM 25-HYDROXYVITAMIN D; D SUPPLEMENTATION; BREAST-CANCER;
 D DEFICIENCY; HYPOVITAMINOSIS D; MORTALITY-RATES; DENTAL-CARIES;
 HUMAN-SKIN; CALCIUM SUPPLEMENTATION; CARDIOVASCULAR-DISEASE
 Vitamin D, traditionally well known for its role in
 maintaining optimal health through its contribution to calcium
 metabolism and skeletal health, has received increased attention
 over the past two decades, with considerable focus being placed on
 its nonskeletal benefits. This paper is a narrative review of the
 nonskeletal health benefits of vitamin D, of particular interest
 to inhabitants of Mediterranean countries, namely, autism, cancer,
 cardiovascular disease, chronic obstructive pulmonary disease,
 dental caries, diabetes mellitus, erectile dysfunction,
 hypertension, metabolic syndrome, respiratory tract infections,
 all-cause mortality, and pregnancy and birth outcomes, because of
 the relatively high incidence and/or prevalence of these disorders
 in this region. Currently, the best evidence is coming out of
 observational studies related to serum 25-hydroxyvitamin D
 [25(OH)D] concentrations. Vitamin D clinical trials have generally
 been poorly designed and conducted, usually being based on vitamin
 D dose rather than 25(OH)D concentration. The optimal 25(OH)D
 concentration is above 75nmol/l (30ng/ml), with even better health
 outcomes in the range of 100-150nmol/l. Achieving these
 concentrations with vitamin D-3 supplements will require 1000-
 4000IU/day of vitamin D-3. Sensible sun exposure should also be
 encouraged. Countries should also consider fortifying grain and
 dairy products with vitamin D-3. [Grant, William B.] Sunlight

Novel liquid-liquid extraction and self-emulsion methods for simplified isolation of extra-virgin olive oil phenolics with emphasis on (-)-oleocanthal and its oral anti-breast cancer activity PLOS ONE English Article

IN-VITRO; INHIBITS PROLIFERATION; OLEOCANTHAL; OLEACEIN; ACTIVATION; EXPRESSION; OLEUROPEIN; COMPOUND Epidemiological and clinical studies compellingly documented the ability of Mediterranean diet rich in extra-virgin olive oil (EVOO) to reduce breast and colon cancers incidence, cardiovascular diseases, and aging cognitive functions decline. (-)-Oleocanthal (OC) and other EVOO phenolics gain progressive research attention due to their documented biological effects against cancer, inflammations, and Alzheimer's disease. There is no simple, reliable, and cost-effective isolation protocol for EVOO phenolics, which hinder their therapeutic applications. This study develops novel methods to isolate OC and other EVOO phenolics. This includes the use of ultra-freezing to eliminate most EVOO fats and the successful water capacity to efficiently extract OC and EVOO phenolics as self-emulsified nano-emulsion. Subsequent resin entrapment and size exclusion chromatography afforded individual EVOO phenolics in high purity. OC in vitro and in vivo oral anti-breast cancer (BC) activities validated its lead candidacy. Effective isolation of EVOO phenolics provided in this study will facilitate future preclinical and clinical investigations and stimulate the therapeutic development of these important bioactive natural products. Phenolic compounds from Mediterranean foods as
nutraceutical tools for the prevention of cancer: The effect of
honey polyphenols on colorectal cancer stem-like cells from
spheroids FOOD CHEMISTRY English Article;
Proceedings Paper 2nd Food Chemistry Conference on Shaping
the Future of Food Quality, Safety, Nutrition and Health SEP 17-
19, 2019 Seville, SPAIN 3D culture; Cancer stem
cells; Chemoresistance; Manuka honey; Self-renewal; Tumorspheres;
Spheroids SELF-RENEWAL CAPACITY; BREAST-CANCER; MODULATION;
RESISTANCE; APOPTOSIS; PATHWAY; TARGET Chemoresistance and
development of relapses are ascribable to a rare cell population
of tumour mass: cancer stem cells (CSCs). Targeting CSCs could
increase patients' survival rate and it is important to identify
molecules that can act on the main pathways of these cells.
Natural bioactive compounds, of which Manuka honey (MH) is rich,
could be a good opportunity to target them. This work aims to
evaluate the effect of MH on CSCs-like from human colorectal
carcinoma (HCT-116 cell line) enriched through the in vitro
sphere-forming assay. The results showed that MH reduced the
volume of the entire culture of spheroids, affecting also their
morphological parameters and induced apoptosis and ROS
intracellular accumulation in CSCs-like. In addition, MH decreased
the mRNA expression of one of ABC transporters (ABCG2) and
affected self-renewal ability through the downregulation of the
mRNA expression of one of the receptor membranes of Wnt/beta-
catenin pathway (Frizzled 7). [Cianciosi, Danila; Ansary,

Uptake and metabolism of olive oil polyphenols in human breast cancer cells using nano-liquid chromatography coupled to electrospray ionization-time of flight-mass spectrometry JOURNAL OF CHROMATOGRAPHY B-ANALYTICAL TECHNOLOGIES IN THE BIOMEDICAL AND LIFE SCIENCES English Article

Olive oil; Phenolic compounds; Cancer cells; Metabolites; Nano-liquid chromatography; Electrospray-time of flight-mass; spectrometry PHENOLIC-COMPOUNDS; IN-VITRO; HYDROXYTYROSOL; PREVENTION; HEALTH; HL60 Polyphenols from extra virgin olive oil (EVOO), a main component of the Mediterranean diet, have demonstrated repeatedly anti-tumor activity in several in vitro and in vivo studies. However, little is known about the efficiency of the absorption process and metabolic conversion of these compounds at cellular level. In this study, a nano liquid chromatography-electrospray ionization-time of flight mass spectrometry (nanoLC-ESI-TOF MS) method was developed to study the cellular uptake and metabolism of olive oil phenols in JIMT-1 human breast cancer cells. After incubation for different time periods with EVOO-derived phenolic extracts, culture media, cytosolic fraction and solid particles fraction were separated and analyzed. Most of the free phenols, mainly hydroxytyrosol, its secoiridoid derivatives, and the flavonoid luteolin, disappeared in the culture media in different ways and at different times. Besides, several metabolites were detected in the culture media, fact that may indicate absorption and intracellular metabolism followed by rapid cellular export. Low intracellular accumulation was observed with only traces of some

compounds detected in the cytosolic and solid particles fractions. Methylated conjugates were the major metabolites detected, suggesting a catalytic action of catechol-O-methyl transferase (COMT) in cancer cells. (C) 2012 Elsevier B.V. All rights reserved. Characterization of Inulin Coated Gold Nanoparticles for Selective
Delivery of Doxorubicin to Breast Cancer Cells JOURNAL OF
NANOMATERIALS English Article

THERAPEUTICS; PACLITAXEL; HYDROGELS; TOOL

A novel folate-targeted gold-based nanosystem for achieving selectivity towards folate receptor (FR) positive cells is proposed, by virtue of the fact that the FR is a molecularly targeted entity overexpressed in a wide spectrum of solid tumors. A new inulin-folate derivative (INU-FA) has been synthesized to act as coating agent for 40 nm gold nanoparticles. The obtained polymer-coated gold nanoparticles (Au@INU-FA) were characterized in terms of hydrodynamic radius, shape, zeta potential, and aqueous stability and were loaded with doxorubicin (Au@INU-FA/Doxo). Its release capability was tested in different release media. The selectivity of Au@INU-FA/Doxo system towards FRs-positive cancer cells was proved by the differences in the quantitative uptake using human breast cancer MCF7 as FR-positive cells and 16HBE epithelial as noncancer cell line. Furthermore, the folate-mediated uptake mechanism was studied by FRs-blocking experiments. On the whole Au@INU-FA/Doxo was able to be preferentially internalized into MCF7 cells proving a folate-mediated endocytosis mechanism which allowed a higher and selective cytotoxic effect towards cancer cells. The cytotoxicity profile was evaluated on both cancer and noncancer cell lines, displaying that folate-mediated targeting implied advantageous therapeutic effects, such as amplified drug uptake and increased anticancer activity towards MCF7 cancer cells. Heterogeneous global health stock and growth: quantitative evidence from 140 countries, 1990-2100 ARCHIVES OF PUBLIC HEALTH English Article

Sustainable development; Health stock; Health forecasting; Time series INCLUSIVE WEALTH; LIFE EXPECTANCY; FERTILITY; IMPACT;

INCOME Background In the prevailing economic perspective, health is viewed as a type of capital stock that yields healthy days' in human society. However, evaluations of this health capital stock are still limited to specific contexts. The primary aim of this study is to measure and forecast the global health stocks in 140 countries from 1990 to 2100. Methods The health capital stock in each country from 1990 to 2015 was estimated using a capital approach. The future health stocks between 2016 and 2100 were forecast using a time-series model. Results Based on the health stocks from 1990 to 2015, low-income countries have much larger and more rapidly growing health stocks. In the long-term, to 2100, upper-middle income countries, particularly countries in the Middle East and North Africa, exhibit great growth that benefits from the peaks in their youth or working-age populations. Immigration also contributes to health stock growth, as do other factors, e.g., the fertility rate, population ageing, and working-age and youth populations. Conclusions Health stock is a vital component of global sustainable development that should be consistently included as a stock-based sustainability index in the evaluations of other capital to accurately measure national wealth and sustainability. WEIGHT; METABOLIC SYNDROME; GREEK ADOLESCENTS; LIFE-STYLE; SAMPLE; CHILDREN; FOOD; COMPONENTS; QUALITY; PREVENTION BACKGROUND:
Among adults, the Mediterranean dietary pattern (MDP) is inversely related to body mass index (BMI). Data are lacking on adherence to

the MDP among youth in the United States and whether the MDP is related to weight change in that group. OBJECTIVE: To assess whether adherence to the MDP was associated with BMI change among adolescents. To examine temporality, we studied the association between baseline and 2-3-year changes in adherence to the MDP with concurrent changes in BMI, as well as subsequent changes in BMI over a 7-year period. METHODS: We prospectively followed 6002 females and 4916 males in the Growing Up Today Study II, aged 8-15 years in 2004, living across United States. Data were collected by questionnaire in 2004, 2006, 2008 and 2011. Dietary intake was assessed by the Youth/Adolescent Questionnaire. The KidMed Index was derived to measure the adherence to the MDP. We used generalized estimating equations with repeated measures within subjects to assess the association between MDP and BMI change. RESULTS: A two-point increment in the KidMed Index was independently associated with a lower gain in BMI (-0.04 kg m^{-2} ; $P = 0.001$). A greater increase in adherence to the KidMed Index was independently related to a lower gain in BMI in both the concurrent ($P\text{-for-trend} < 0.001$) and the subsequent period ($P\text{-for-trend} = 0.002$). CONCLUSIONS: Adherence to MDP was inversely associated with change in BMI among adolescents. Two-year improvement in adherence to MDP was independently associated with less steep gain in the BMI in both the concurrent and the subsequent period.

Associations between Polycyclic Aromatic Hydrocarbon-Related
Exposures and p53 Mutations in Breast Tumors ENVIRONMENTAL HEALTH
PERSPECTIVES English Article

breast cancer; p53 mutation; p53 overexpression;
PAH; polycyclic aromatic hydrocarbons CIGARETTE-SMOKING; RISK-
FACTORS; CANCER RISK; DNA-ADDUCTS; LONG-ISLAND; TOBACCO-SMOKE;
EXPRESSION; DAMAGE; MEAT; POLLUTION BACKGROUND: Previous
studies have suggested that polycyclic aromatic hydrocarbons
(PAHs) may be associated with breast cancer. However, the
carcinogenicity of PAHs on the human breast remains unclear.
Certain carcinogens may be associated with specific mutation
patterns in the p53 tumor suppressor gene, thereby contributing
information about disease etiology. OBJECTIVES: We hypothesized
that associations of PAH-related exposures with breast cancer
would differ according to tumor p53 mutation status, effect, type,
and number. METHODS: We examined this possibility in a population-
based case control study using polytomous logistic regression. As
previously reported, 151 p53 mutations among 859 tumors were
identified using Surveyor nuclease and confirmed by sequencing.
RESULTS: We found that participants with p53 mutations were less
likely to be exposed to PAHs (assessed by smoking status in 859
cases and 1,556 controls, grilled/smoked meat intake in 822 cases
and 1,475 controls, and PAH-DNA adducts in peripheral mononuclear
cells in 487 cases and 941 controls) than participants without p53
mutations. For example, active and passive smoking was associated
with p53 mutation negative [odds ratio (OR) = 1.55; 95% confidence
interval (CI), 1.11-2.15] but not p53 mutation positive (OR =
0.77; 95% CI, 0.43-1.38) cancer (ratio of the ORs = 0.50, $p <$
0.05). However, frameshift mutations, mutation number, G:C → A:T
transitions at CpG sites, and insertions/deletions were
consistently elevated among exposed subjects. CONCLUSIONS: These
findings suggest that PAHs may be associated with specific breast
tumor p53 mutation subgroups rather than with overall p53
mutations and may also be related to breast cancer through
mechanisms other than p53 mutation. [Mordukhovich, Irina;

LC-MS/MS Phytochemical Profiling, Antioxidant
Activity, and Cytotoxicity of the Ethanolic Extract of *Atriplex*
halimus L. against Breast Cancer Cell Lines: Computational Studies
and Experimental Validation PHARMACEUTICALS English

Article *Atriplex halimus* L.;
antioxidant activity; cytotoxicity; breast cancer; computational
study; ADMET analysis; toxicity prediction CARBONIC-ANHYDRASE
INHIBITORS; GALLIC ACID; METABOLIZING ENZYMES; ADENOSINE-
DEAMINASE; MOLECULAR DOCKING; DRUG TRANSPORTERS; MEDICINAL-PLANTS;
OXIDATIVE STRESS; AQUEOUS EXTRACT; IN-SILICO *Atriplex halimus* L.,
also known as Mediterranean saltbush, and locally as "Lgtef", an
halophytic shrub, is used extensively to treat a wide variety of
ailments in Morocco. The present study was undertaken to determine
the antioxidant activity and cytotoxicity of the ethanolic extract
of *A. halimus* leaves (AHEE). We first determined the phytochemical
composition of AHEE using a liquid chromatography (LC)-tandem mass
spectrometry (MS/MS) technique. The antioxidant activity was
evaluated using different methods including DPPH scavenging
capacity, beta-carotene bleaching assay, ABTS scavenging, iron
chelation, and the total antioxidant capacity assays. Cytotoxicity
was investigated against human cancer breast cells lines MCF-7 and
MDA-MB-231. The results showed that the components of the extract
are composed of phenolic acids and flavonoids. The DPPH test
showed strong scavenging capacity for the leaf extract (IC₅₀ of
0.36 +/- 0.05 mg/mL) in comparison to ascorbic acid (IC₅₀ of 0.19
+/- 0.02 mg/mL). The beta-carotene test determined an IC₅₀ of 2.91
+/- 0.14 mg/mL. The IC₅₀ values of ABTS, iron chelation, and TAC
tests were 44.10 +/- 2.92 TE μ mol/mL, 27.40 +/- 1.46 mg/mL, and
124 +/- 1.27 μ g AAE/mg, respectively. In vitro, the AHE extract
showed significant inhibitory activity in all tested tumor cell
lines, and the inhibition activity was found in a dose-dependent
manner. Furthermore, computational techniques such as molecular
docking and ADMET analysis were used in this work. Moreover, the
physicochemical parameters related to the compounds'
pharmacokinetic indicators were evaluated, including absorption,
distribution, metabolism, excretion, and toxicity prediction (Pro-
Tox II). [Elbouzidi, Amine; Meskali, Nada; Addi, Mohamed] Univ

 Results of ROSE/TRIO-12, a Randomized Placebo-Controlled Phase III Trial Evaluating the Addition of Ramucirumab to First-Line Docetaxel Chemotherapy in Metastatic Breast Cancer JOURNAL OF CLINICAL ONCOLOGY English Article
 ENDOTHELIAL GROWTH-FACTOR; CELL LUNG-CANCER; NEOADJUVANT CHEMOTHERAPY; DOUBLE-BLIND; BEVACIZUMAB; ANGIOGENESIS; THERAPY; VEGFR-1; OVARIAN Purpose Currently,

antiangiogenic strategies in metastatic breast cancer have demonstrated modest improvements in progression-free survival (PFS) but not improved quality or duration of survival, warranting evaluation of new agents in a placebo-controlled setting. Ramucirumab is a human immunoglobulin G1 antibody that binds vascular endothelial growth factor receptor-2 and blocks ligand-stimulated activation. The ROSE/TRIO-012 trial evaluated ramucirumab with docetaxel in unresectable, locally recurrent, or metastatic breast cancer. Patients and Methods In this double-blind, placebo-controlled, randomized, multinational phase III trial, 1,144 patients with human epidermal growth factor receptor 2 (HER2) -negative breast cancer who had not received cytotoxic chemotherapy in the advanced setting were randomly assigned at a two-to-one ratio to receive docetaxel 75 mg/m² plus ramucirumab 10 mg/kg or docetaxel 75 mg/antiangiogenic plus placebo once every 3 weeks. Treatment continued until disease progression, unacceptable toxicity, or other withdrawal criteria. Patients were stratified by previous taxane therapy, visceral metastasis, hormone receptor status, and geographic region. An independent data monitoring committee oversaw the trial. The primary end point was investigator-assessed PFS. Results Median PFS in patients treated with ramucirumab plus docetaxel was 9.5 months, compared with 8.2 months in patients who received placebo plus docetaxel (hazard ratio [HR], 0.88; P = .077). Median overall survival was 27.3 months in patients who received ramucirumab plus docetaxel, compared with 27.2 months in patients who received placebo plus docetaxel (HR, 1.01; P = .915). Toxicities seen at significantly higher rates in patients receiving ramucirumab included fatigue, hypertension, febrile neutropenia, palmar-plantar erythrodysesthesia syndrome, and stomatitis. Conclusion Addition of ramucirumab to docetaxel in HER2-negative advanced breast cancer did not meaningfully improve important clinical outcomes.

Papanicolaou Smear Findings in Solid-Organ

Transplant Recipients Compared With Normal Subjects According to the Bethesda 2001 System EXPERIMENTAL AND CLINICAL

TRANSPLANTATION English Article; Proceedings Paper

14th Congress of the Middle-East-Society-for-Organ-

Transplantation / 5th Middle East Transplant Games SEP 10-13, 2014

Istanbul, TURKEY Cervical cancer;

Immunosuppression; Kidney transplant; Liver transplant; Pap smear

CERVICAL INTRAEPITHELIAL NEOPLASIA; HUMAN-PAPILLOMAVIRUS;

REGRESSION; INFECTION; WOMEN Objectives: Solid-organ transplant

recipients are at increased risk of developing cancer including

cervical cancer compared with woman in the general population,

mostly due to long-term immunosuppressive therapy. The

Papanicolaou smear remains the primary method of screening

cervical pathology including preinvasive and invasive lesions. The

objective of this study was to evaluate Pap smear findings in

solid-organ transplant recipients, determine the prevalence of

abnormal smears, and compare these patients with the general

population. Materials and Methods: We retrospectively examined 111

women patients who received liver or kidney transplant between

January 1990 to December 2012 at Baskent University Ankara

Hospital. Pap smear findings were compared with normal control

patients matched for same age and technical procedure of cervical

cytology. To selection of control patients, propensity score

matching program was performed. All Pap smears were re-examined

according to Bethesda 2001 criteria. Results: In 111 transplant

patients, 2 patients (1.8%) had atypical squamous cells of

undetermined significance, 8 patients (7.2%) had low-grade

squamous intraepithelial lesion, 15 patients (13.5%) had Candida

infection, 2 patients (1.8%) had Trichomonas vaginalis, 1 patient

(0.9%) had herpes simplex infection, 13 patients (11.7%) had

bacterial vaginosis, 15 patients (13.5%) had reactive changes due

to inflammation, and 18 patients (16.2%) had atrophy. When we compared our results with the control group, there were statistically significant differences ($P \leq .05$) between the 2 groups in epithelial cell abnormalities (low-grade squamous intraepithelial lesion), Candida infection, bacterial vaginosis, and atrophy. Conclusions: Pap smear screening potentially may help recognize cervical preinvasive and invasive lesions. The risk of developing cervical intraepithelial neoplasia is greater in transplant recipients because of immunosuppressive therapy. The incidence of low-grade squamous intraepithelial lesion was significantly greater in transplant recipients than the general population. Intensive follow-up with Pap smear in transplant recipients is important in the early detection of these lesions.

J Pourianazar, NT; Gunduz, U Pourianazar, Negar Taghavi; Gunduz, Ufuk CpG oligodeoxynucleotide-loaded PAMAM dendrimer-coated magnetic nanoparticles promote apoptosis in breast cancer cells BIOMEDICINE & PHARMACOTHERAPY English Article

PAMAM dendrimer; Drug delivery; Flow cytometry; CpG-ODN; Cancer therapy; Targeted therapy TOLL-LIKE-RECEPTORS; HUMAN INTESTINAL EPITHELIUM; IRON-OXIDE NANOPARTICLES; NF-KAPPA-B; HELICOBACTER-PYLORI; DELIVERY; TLR9; EXPRESSION; DNA; OLIGONUCLEOTIDES One major application of nanotechnology in cancer treatment involves designing nanoparticles to deliver drugs, oligonucleotides, and genes to cancer cells. Nanoparticles should be engineered so that they could target and destroy tumor cells with minimal damage to healthy tissues. This research aims to develop an appropriate and efficient nanocarrier, having the ability of interacting with and delivering CpG-oligodeoxynucleotides (CpG-ODNs) to tumor cells. CpG-ODNs activate Toll-like receptor 9 (TLR9), which can generate a signal cascade for cell death. In our study, we utilized three-layer magnetic

nanoparticles composed of a Fe₃O₄ magnetic core, an aminosilane (APTS) interlayer and a cationic poly(amidoamine) (PAMAM) dendrimer. This will be a novel targeted delivery system to enhance the accumulation of CpG-ODN molecules in tumor cells. The validation of CpG-ODN binding to DCMNPs was performed using agarose gel electrophoresis, UV-spectrophotometer, XPS analyses. Cytotoxicity of conjugates was assessed in MDA-MB231 and SKBR3 cancer cells based on cell viability by XTT assay and flow cytometric analysis. Our results indicated that the synthesized DCMNPs having high positive charges on their surface could attach to CpG-ODN molecules via electrostatic means. These nanoparticles with the average sizes of 40 +/- 10 nm bind to CpG-ODN molecules efficiently and induce cell death in MDA-MB231 and SKBR3 tumor cells and could be considered a suitable targeted delivery system for CpG-ODN in biomedical applications. The magnetic core of these nanoparticles represents a promising option for selective drug targeting as they can be concentrated and held in position by means of an external magnetic field. English Article breast cancer; Mediterranean diet; olive oil minor compounds; hydroxytyrosol; tyrosol; phenols; oxidative stress; reactive oxygen species; DNA damage OLIVE OIL PHENOLICS; ANTIOXIDANT PROPERTIES; EPITHELIAL-CELLS; CANCER CELLS; CARCINOGENESIS; TYROSOL; STRESS; HEALTH; LINES; ASSAY Over recent years, several

studies have related olive oil ingestion to a low incidence of several diseases, including breast cancer. Hydroxytyrosol and tyrosol are two of the major phenols present in virgin olive oils. Despite the fact that they have been linked to cancer prevention, there is no evidence that clarifies their effect in human breast tumor and non-tumor cells. In the present work, we present hydroxytyrosol and tyrosol's effects in human breast cell lines. Our results show that hydroxytyrosol acts as a more efficient free radical scavenger than tyrosol, but both fail to affect cell proliferation rates, cell cycle profile or cell apoptosis in human mammary epithelial cells (MCF10A) or breast cancer cells (MDA-MB-231 and MCF7). We found that hydroxytyrosol decreases the intracellular reactive oxygen species (ROS) level in MCF10A cells but not in MCF7 or MDA-MB-231 cells while very high amounts of tyrosol is needed to decrease the ROS level in MCF10A cells. Interestingly, hydroxytyrosol prevents oxidative DNA damage in the three breast cell lines. Therefore, our data suggest that simple phenol hydroxytyrosol could contribute to a lower incidence of breast cancer in populations that consume virgin olive oil due to its antioxidant activity and its protection against oxidative DNA damage in mammary cells.

oncology; nutrition; supportive care; integrative oncology; metabolism; mitochondria ANDROGEN DEPRIVATION THERAPY; QUALITY-OF-LIFE; PROSTATE-CANCER; GENE-EXPRESSION; NUTRITION; RISK; MEN; MITOCHONDRIA; PREVALENCE; OUTCOMES Simple Summary Cancer-related fatigue affects the majority of people undergoing chemotherapy for cancer. The Mediterranean Diet provides healthy macro- and micronutrients that promote energy production and counter known mechanisms that contribute to fatigue. Thus, we designed a Mediterranean Diet program specifically for patients undergoing chemotherapy that included food provision, education, a cookbook, and weekly telephone check-ins. In a two-arm randomized controlled trial (n = 33), we found that our program was safe and feasible; there was excellent adherence (>70%) to the Mediterranean Diet. The Mediterranean Diet program led to less fatigue to a small-moderate degree at weeks 4 and 8. For those with a lower Mediterranean Diet score before the program, the program had a larger effect. Mitochondria are the cellular organelles that produce ATP energy and, in circulating T cells, fatigue was associated with mitochondrial dysfunction. These data support larger studies testing how and how much a Mediterranean Diet during chemotherapy can alleviate fatigue. Cancer-related fatigue is a common, burdensome symptom of cancer and a side-effect of chemotherapy. While a Mediterranean Diet (MedDiet) promotes energy metabolism and overall health, its effects on cancer-related fatigue remain unknown. In a randomized controlled trial, we evaluated a rigorous MedDiet intervention for feasibility and safety as well as preliminary effects on cancer-related fatigue and metabolism compared to usual care. Participants had stage I-III cancer and at least six weeks of chemotherapy scheduled. After baseline assessments, randomization occurred 2:1, MedDiet:usual care. Measures were collected at baseline, week 4, and week 8 including MedDiet adherence (score 0-14), dietary intake, and blood-based metabolic measures. Mitochondrial respiration from freshly isolated T cells was measured at baseline and four weeks. Participants (n = 33) were 51.0 +/- 14.6 years old, 94% were female, and 91% were being treated for breast cancer. The study was feasible, with 100% completing the study and >70% increasing their MedDiet adherence at four and eight weeks compared to baseline. Overall, the MedDiet intervention vs. usual care had a small-moderate effect on change in fatigue at weeks 4 and 8 (ES = 0.31, 0.25, respectively). For those with a baseline MedDiet score <5 (n = 21), the MedDiet intervention had a moderate-large effect of 0.67 and 0.48 at weeks 4 and 8, respectively. The MedDiet did not affect blood-based lipids, though it had a beneficial effect on fructosamine (ES = -0.55). Fatigue was associated with mitochondrial dysfunction including lower basal respiration, maximal respiration, and spare capacity (p < 0.05 for FACIT-F fatigue subscale and BFI, usual fatigue). In conclusion, the MedDiet was feasible and attenuated cancer-related fatigue among patients undergoing chemotherapy, especially those with lower MedDiet scores at baseline. smear; Cervical cancer; Vaccination; Jordan CERVICAL INTRAEPITHELIAL NEOPLASIA; EXTENDED MIDDLE-EAST; MOLECULAR EPIDEMIOLOGY; MULTIPLE TYPES; CANCER; INFECTION; RISK; GENOTYPE; HPV; CARCINOMA Background: Infection with human papillomavirus (HPV) is the most common sexually transmitted infection in women worldwide. Infection with high-risk HPV (HR-HPV) is the main cause of cervical cancer. However, little is known about its prevalence in the female population in Jordan. The aim of this study was to discover HPV type-specific prevalence in women living in Jordan. Data regarding HPV type-specific prevalence for a particular country are crucial for providing baseline information to estimate the effectiveness of implementing HPV-based cervical cancer prevention. Materials and Methods: Between 2008 and 2014, cervical epithelium samples were collected by conventional Papanicolaou (Pap) smear; all abnormal smears had reflex HPV testing from apparently healthy and non-healthy women. HPV prevalence and its genotype distribution were examined in these smears. DNA samples were extracted and HPV genotyping was performed. The results were retrospectively analyzed. Results: A total of 209 abnormal Pap smears were identified and reflex HPV testing was performed on these cases; 153 (73.2%) of the tested cases were HPV positive. The mean age of the women included was 38.3 +/- 10.2 (range: 20-70) years and the mean age of HPV-positive women was 38.5 +/- 10.3 (range: 21-70) years. There was a significant increase in the incidence of HPV infection over the study period. HPV 6 and 11 infections were very common in the HPV positive women; 38.6% and 47%, respectively. HPV 16 was the single most common (57.5%) HPV infection detected. HPV 30's (31, 33, 34, 35, and 39) as a group were the most common HPV infections recorded at 59.5%. HPV 50's (51, 52, 53, 56, 58, and 59) were detected in 56.9% of the cases. HPV type 68 was recorded in one case (0.6%). Of notice, the vast majority of cases had co-infection of multiple genotypes (89%) and only 11% were single genotype infection. Conclusion: The results of the study showed a relatively high prevalence (73.2%) of HPV infection and a higher incidence of co-infection with multiple high risk genotypes (89%) in comparison with other studies from the present region. This study suggests that there is sufficient evidence to warrant further population-based studies and further interventions. HPV vaccination should be considered for Jordanian girls as a preventative measure. [Freij, M. A.; Khadra, M. M.; Rahall, B.  Gok, Seher; Kuzmenko, Oleksandr; Babinskyi, Andrii;
 Severcan, Feride Vitamin E Derivative with Modified
 Side Chain Induced Apoptosis by Modulating the Cellular Lipids and
 Membrane Dynamics in MCF7 Cells CELL BIOCHEMISTRY AND BIOPHYSICS
 English Article

Vitamin E derivative; Tocopherol; Lipid metabolism; Breast
 cancer; Spectroscopy ALPHA-TOCOPHERYL SUCCINATE; APOLIPOPROTEIN-
 E GENOTYPE; BREAST-CANCER CELLS; E ANALOGS; BIOCHEMICAL-
 COMPOSITION; TUMOR BURDEN; MODEL; METABOLISM; PROSTATE; FLUIDITY

The vitamin E derivative with side chain modification
 (TC6OAc) has been shown to possess anticancer activity in our
 earlier in vivo studies. It was hypothesized that, as Vitamin E
 (VE) and VE derivative are fat soluble lipophilic molecules, they
 exert their function by modulating the lipid metabolism and
 related pathways. This study aimed to evaluate the cellular impact
 of this VE derivative (2,5,7,8-Tetramethyl-2-(4 '-Methyl-3 '-
 Pentenyl)-6-Acetoxy Chromane-TC6OH), using alpha-tocopherol as a
 reference compound throughout the experiments. Their effects on
 the cellular metabolism, the biophysical properties of cellular
 lipids and the functional characteristics of cells were monitored
 in human estrogen receptor (ER) positive breast cancer cells. It
 has been documented that TC6OH treatment induces tumor cell
 apoptosis by dissipating the mitochondrial membrane potential,
 modulating the lipid, transportation and degradation as well as
 downregulating certain anti-apoptotic and growth factor related
 proteins. Due to resistance of ER positive cells to the
 established therapies, the findings of this study are of
 translational value. [Gok, Seher] Sci & Technol Res Council

J Shtaiwi, A; Adnan, R; Khairuddean, M; Khan, SU
Shtaiwi, Amneh; Adnan, Rohana; Khairuddean, Melati;
Khan, Shafi Ullah Computational investigations of
the binding mechanism of novel benzophenone imine inhibitors for
the treatment of breast cancer RSC ADVANCES
English Article

ESTROGEN-RECEPTOR-ALPHA; MOLECULAR-DYNAMICS SIMULATIONS;
SIDE-CHAIN; ACTIVATION; MODULATORS; LIGANDS; AFFINITY; DESIGN;
ANTIESTROGENS; OPTIMIZATION 4-Hydroxytamoxifen (4-OHT), the most
common hormone used for the treatment of breast cancer, is a
selective estrogen receptor modulator (SERM) inhibitor that acts
as an antagonist in breast tissue and a partial agonist in the
endometrium. However, the detailed molecular mechanism of 4-OHT
structure modification has not been well investigated to date.
Herein, molecular docking, molecular dynamics simulations and free
energy calculations were performed to explore the mechanisms of
the molecular interactions between newly designed benzophenone
imines (BIs) and the three forms apo, antagonist and agonist of
the human estrogen receptor hER alpha. The proposed inhibitors
were designed by replacing the triarylethylene estrogenic scaffold
found in 4-OHT with Schiff base triarylimine derivatives. The
antiestrogen scaffold i.e. the O-alkyl side chain in 4-OHT was
developed by incorporating an alanine amino acid side chain
functionality into the triarylimine scaffold. Docking results
reveal that the newly designed BIs bind to the hydrophobic open
pocket of the apo and antagonist hER alpha conformations with
higher affinity as compared to the natural and synthetic estrogen
estradiol (E2) and 4-OHT. The analysis of the molecular dynamics
simulation results based on six different systems of the best
docked BI (5c) with hER alpha receptors demonstrates stable
interactions, and the complex undergoes fewer conformational
fluctuations in the open apo/antagonist hER alpha receptors as
compared to the case of the closed agonist. In addition, the
calculated binding free energies indicate that the main factor
that contributes to the stabilization of the receptor-inhibitor
complexes is hydrophobic interactions. This study suggests that
the development of these Schiff base derivatives may be worth
exploring for the preparation of new 4-OHT analogues. [Shtaiwi,

Pollution of river systems in Tunisia by endocrine disrupting compounds (EDCs) is due to anthropogenic impacts through non-treated industrial wastewater and municipal-treated wastewater discharge. The aim of this study was to assess the estrogenic activity of environmental matrices involving raw industrial wastewater (WW), surface water (SW), and treated wastewater (TWW). A modified E-screen assay was used to evaluate estrogenic activity of the samples in MCF-7 breast cancer cells. Western blotting and real-time PCR molecular approaches were applied to investigate the mechanism of EDC-induced MCF-7 breast cancer cell proliferation which interferes with estrogen receptor alpha (ER alpha) and c-Jun. Our results revealed a dose-dependent estrogenic activity reaching an optimal level at a concentration of 0.01% for industrial WW and SW and 10% for TWW. Monitoring ER alpha protein and c-Jun gene expression levels after 1, 6, 24, and 48 h of treatment showed a correlation in the overexpression of ER alpha and c-Jun most of the time. In fact, ER alpha and c-Jun correlated up-regulation began after 1 h of treatment for industrial WW, TWW, and one SW sample. For the other SW samples, this correlated up-regulation started after 6-24 h of treatment. Results emphasized the estrogen-like effect of our contaminated samples on MCF-7 cells which facilitate a crosstalk between ER alpha and c-Jun factor, thereby directly regulating the expression of estrogen-induced genes to mediate breast cancer cell growth.

Barriers and Facilitators to Adherence to a
Mediterranean Diet Intervention during Chemotherapy Treatment: A
Qualitative Analysis NUTRITION AND CANCER-AN INTERNATIONAL
JOURNAL English Article

CANCER-RELATED FATIGUE; CONTROLLED-TRIAL;
NUTRITION; BREAST; HEALTH; GUIDELINES; DIAGNOSIS; IMPACT Patients
undergoing chemotherapy are at risk for malnutrition and a high
symptom burden, and nutritional interventions can address clinical
and supportive care outcomes. Herein, we identified barriers and
facilitators to adhering to a Mediterranean Diet (MedDiet)
intervention during chemotherapy. Patients with cancer (any type)
who were undergoing chemotherapy were enrolled into a clinical
trial testing the effects of an 8-week MedDiet intervention on
cancer-related fatigue. Participants were randomized 2:1,
MedDiet:control. The intervention entailed food provision,
education, a cookbook, a session with a nutritionist, and weekly
check-ins. Post-intervention, all participants completed semi-
structured exit interviews. The interviews were transcribed and
open coding was conducted to describe the facilitators and
barriers to MedDiet adherence. Participants (n = 29, n = 21 in the
intervention group) were 51.0 +/- 15.1 years old and 93.1% had
breast cancer. Educational materials and convenient food delivery
were the highest reported facilitators. Many patients offered that
changing their diet gave a sense of control and empowerment.
Barriers to adherence were that the frozen food was unappetizing,
participants' (or their spouse/children's) food preferences did
not align with the MedDiet, and chemotherapy-induced side effects
that prevented food consumption (eg, mouth sores, lack of
appetite). This project helps understand the patient experience
within nutritional interventions to optimize dietary programs

during chemotherapy treatment. BMC PUBLIC HEALTH English Article

HPV infection; HPV vaccine; Cervical cancer; Qatar; University students HUMAN-PAPILLOMAVIRUS VACCINE; ABNORMAL CERVICAL CYTOLOGY; NORTH-AFRICA; MIDDLE-EAST; INTERVENTIONS; WOMEN; EPIDEMIOLOGY; COVERAGE; CANCER

Background Human Papilloma Virus (HPV) infection is a

significant public health concern in the Gulf Cooperation Council countries, being widely prevalent and the main risk factor for cervical cancer. We aimed to assess knowledge and perception towards HPV, acceptability of the HPV vaccine, and HPV vaccination rates among university students in Education City, Doha, Qatar.

Methods This cross-sectional survey utilized proportional quota-sampling, with quotas based on university, sex, and nationality, to recruit students from seven universities between February and September 2022. The English language questionnaire requested socio-demographic information, knowledge, and attitudes about HPV infection and the vaccine. The chi-square test, Student t-test, Mann-Whitney-Wilcoxon tests and multivariable ordinal logistic regression were used to assess differences in proportion, mean, and median according to broad HPV knowledge categories.

Results Three hundred and ninety-eight students were recruited (response rate = 82.3%), of whom 251 (63.1%) were female. Mean age was 21.7 years. Eighty-nine (22.4%, 95% CI 18.4-26.8%) students had poor knowledge about HPV, 220 (55.3%, 95% CI 50.2-60.2%) students had some awareness, and 89 (22.4%, 95% CI 18.4-26.8%) students were knowledgeable. Age, nationality, and field of study influenced the students' knowledge about HPV. Only 25 (6.3%) students had previously been vaccinated against HPV. However, 71% of the unvaccinated students reported being willing to get vaccinated if recommended by their healthcare provider.

Conclusions Overall, 77.7% of the student population had some-to-good levels of knowledge about HPV-related infection, cancer, and vaccination. There are gaps in the student population's understanding and knowledge about HPV. Increasing knowledge can be key toward shared decision-making for HPV vaccination among eligible populations. Targeted public health campaigns and integration into childhood vaccination programs should be critical first steps, especially as most of the surveyed students had a positive outlook on getting vaccinated. Healthcare professionals should be incentivized to increase their HPV knowledge and communication skills, while policymakers can work toward easing barriers in integrating HPV vaccinations in the immunization schedule and encouraging overall HPV vaccination uptake.

J Djuric, Z; Ren, JW; Blythe, J; VanLoon, G; Sen, A
Djuric, Zora; Ren, Jianwei; Blythe, Jason; VanLoon,
Glee; Sen, Ananda A Mediterranean dietary
intervention in healthy American women changes plasma carotenoids
and fatty acids in distinct clusters NUTRITION RESEARCH
English Article

Cancer prevention; Monounsaturated fat; Fruit; Vegetables;
Olive oil; Human; Clinical trial; Carotenoids BREAST-CANCER;
INSULIN-RESISTANCE; SERUM CAROTENOIDS; POOLED ANALYSIS; BODY-
WEIGHT; RISK; BIOMARKERS; VEGETABLES; SURVIVAL; COHORT This
study examined patterns of changes in plasma fatty acids and
carotenoids when women were asked to follow a novel, Greek-
Mediterranean exchange list diet. A total of 69 healthy, nonobese
women ages 25 to 59 years were randomized either to continue their
own usual diet or to follow a modified Mediterranean diet for 6
months. There were no significant changes in blood lipids,
triacylglycerol, insulin, glucose, or C-reactive protein. Mean
plasma carotenoids increased by 55%, which is consistent with a
large increase in fruit and vegetable consumption. Likewise,
changes in fat intakes were reflected in blood fatty acids, with a
25% increase in mean plasma monounsaturated fatty acids. Principal
component analysis was conducted to examine the sources of
interindividual variation for changes in carotenoid and fatty acid
levels. Changes in the Mediterranean diet were clustered together
in 4 components that accounted for 78% of the variance in plasma
levels. Increases in plasma lutein, α -carotene, and beta-carotene
clustered together in a "vegetable" pattern, and increases in
carotenoids found in fruit, beta-cryptoxanthin and zeaxanthin also
clustered together but accounted for less of the variance.
Increases in plasma monounsaturated fatty acids were clustered
with a decrease in plasma polyunsaturated fatty acids, consistent
with substitution in the type of oils consumed. The only
association of fatty acid levels with carotenoids was that of
lycopene, which clustered together with an increase in saturated
fatty acids. The changes in blood levels indicate the exchange
list diet was effective for targeting Mediterranean nutrient
intakes using foods available in the United States. (c) 2009

Differential Glycosylation Levels in Saliva from Patients
with Lung or Breast Cancer: A Preliminary Assessment for Early
Diagnostic Purposes METABOLITES English Article

HPEAC-PAD; glycoprotein;
glycomics; glycosylation; saliva; early diagnosis; lung cancer;
breast cancer; fucose; mannose; glucosamine CELL-WALL
POLYSACCHARIDES; EXCHANGE CHROMATOGRAPHY; N-GLYCOSYLATION; ORAL-
CANCER; BIOMARKERS; SERUM; DISCOVERY; FUCOSE Glycans play a
fundamental role in several biological processes, such as cell-
cell adhesion, signaling, and recognition. Similarly, abnormal
glycosylation is involved in many pathological processes, among
which include tumor growth and progression. Several highly
glycosylated proteins found in blood are currently used in
clinical practice as cancer biomarkers (e.g., CA125, PSA, and
CA19-9). The development of novel non-invasive diagnostic
procedures would greatly simplify the screening and discovery of
pathologies at an early stage, thus also allowing for simpler
treatment and a higher success rate. In this observational study
carried out on 68 subjects diagnosed with either breast or lung

cancer and 34 healthy volunteers, we hydrolyzed the glycoproteins in saliva and quantified the obtained free sugars (fucose, mannose, galactose, glucosamine, and galactosamine) by using high-performance anion-exchange chromatography with pulsed-amperometric detection (HPAEC-PAD). The glycosidic profiles were compared by using multivariate statistical analysis, showing differential glycosylation patterns among the three categories. Furthermore, Receiver Operating Characteristics (ROC) analysis allowed obtaining a reliable and minimally invasive protocol able to discriminate between healthy and pathological subjects. Respiratory Health in Migrant Populations: A

lung; asthma; deportation; sleep; refugees POSTTRAUMATIC-STRESS-DISORDER; INJECTION-DRUG USERS; DEPORTATION EXPERIENCES; SLEEP DISTURBANCE; HIV-INFECTION; UNITED-STATES; RISK-FACTORS; TIJUANA; ASTHMA; ACCULTURATION The crisis in the Middle East has raised awareness about the challenges encountered by migrant populations, in particular, health-care access and delivery. Similar challenges are encountered by migrant populations around the world, including those entering the United States as refugees and/or survivors of torture as well as Mexicans and other Latin Americans crossing the border. During the 2016 International American Thoracic Society Meeting held in San Francisco, California, a group of researchers and health-care providers discussed these challenges at a minisymposium devoted to the respiratory health of migrants. The discussion focused on the increased incidence of airway diseases among individuals migrating to more developed countries, the problems created by sleep disorders and their implications for cardiovascular and mental health, the challenges inherent in the control of infections in refugee populations, and the problems resulting from deportation. The group also discussed the potential impact of novel strategies made available by Internet-based technologies and how these strategies could be deployed to support worldwide efforts in assisting migrants and refugees, even in countries that find themselves in the direst circumstances. These presentations are summarized in this document, which is not meant to be exhaustive, but to improve awareness about the challenges confronted by migrants and their host nations regarding respiratory health-care access and delivery, and about the need for adequate investment of resources to better define these challenges through research and for the development of efficient strategies for intervention.

Global relationship between Mediterranean diet and the
incidence and mortality of ischaemic heart disease EUROPEAN
JOURNAL OF PUBLIC HEALTH English Article

BREAST-CANCER; RISK; ADHERENCE;
INDEXES; HEALTH; SCORE Background: The purpose of this study was
to clarify the global relationship between the Mediterranean diet
score (MDS) and country-wise incidence and mortality of ischaemic
heart disease (IHD) using an international database. Methods: We
used population data from a global longitudinal database covering
137 countries with a population of over one million. MDS were
evaluated based on the total score of the nine foods that comprise
the Mediterranean diet. The incidence and mortality of IHD by
country was derived from the Global Burden of Disease (GBD)
database. Average food (g/day/capita) and energy supply
(kcal/day/capita) by country, excluding loss between production
and household, were obtained from the Food and Agriculture
Organization of the United Nations Statistics Division database.
Data from the GBD database were used for body mass index, current
smoking rates, physical activity, years of education and
percentage of the Muslim population. We identified the percentage
of the population over 65 years of age (aging rate) and gross
domestic product per capita (US\$/capita) using the World Bank
database. A linear mixed-effect model was used for evaluating the

effects of MDS on incidence and mortality of IHD controlled for socioeconomic and lifestyle variables. Results: Analysis showed that MDS was significantly associated with IHD incidence after controlling for covariates (-1.01 +/- 0.27, P< 0.001). Similarly, there was a significant association between MDS and IHD-related mortality after controlling for covariates (-0.73 +/- 0.34, P< 0.05). Conclusion: Analysis of 27 years of data suggests that a Mediterranean diet might have a preventive effect on IHD.

MURVET Cellular uptake and apoptotic potential of
rhenium labeled magnetic protein cages in MDA-MB-231 cells
ENVIRONMENTAL TOXICOLOGY AND PHARMACOLOGY
English Article

Magnetoferitin; Cytotoxicity; Apoptosis; Breast cancer cell
lines CANCER-CELLS; OXIDE NANOPARTICLES; CYTOTOXICITY;
APOFERRITIN; TOXICITY; FERRITIN; STRESS Re-188-magnetoferitin
nanoparticles (NPs) provide an attractive platform for localized
radiation therapy due to their magnetic targeting capability while
enhancing contrast in magnetic resonans imaging (MRI) signals. In
this study, cellular uptake, in vitro cytotoxicity, apoptotic
potential of a non-radioactive isotope of rhenium in the form of
Re-187-magnetoferitin NPs were evaluated in both human normal
mammary epithelial and breast metastatic adenocarcinoma cell
lines. The results showed that, NP administration into the cells

is through receptor mediated endocytosis and cancer cells displayed significantly higher uptake and cytotoxicity compared to normal cells. IC50 values of nanoparticles were calculated as 0.96 mg/mL for cancer and 1.73 mg/mL for normal cells. Annexin V/ Propidium Iodide (PI) staining also showed that, NPs induced higher apoptotic rates in cancer cells compared to normal cells. Gene expression analyses confirming the results showed that, pro-apoptotic PUMA and BAX genes were significantly up-regulated while anti-apoptotic BCL-2 and SURVIVIN genes were down-regulated in cancer cells compared to normal cells. Overall, these in vitro results suggest that, Re-187-magnetoferritin NPs have a promising potential for cancer therapy and can be used for imaging and diagnostic purposes for breast cancer at concentrations lower than 0.96 mg/mL. At concentrations above 1 mg/mL, NPs induce apoptosis which can also be used for cancer treatments. [Asik, Elif;

Environmental Radioactivity, Ecotoxicology
(²³⁸U, ²³²Th and ⁴⁰K) and
Potentially Toxic Elements in Water and Sediments from North
Africa Dams SUSTAINABILITY English Article

radioactivity; water quality;
potentially toxic elements; health risks; potential toxicity

NATURAL RADIONUCLIDES; FERTILIZERS; SAMPLES; RIVER The
natural radioactivity of U-238, Th-232 and K-40 was measured in
water and sediment samples collected from Sidi Salem dam (Tunisia)
and A & iuml;n Dalia dam (Algeria) in the Tuniso-Algerian
transboundary basin. The samples were measured using a TERRA
detector of gamma, beta, and alpha rays, and atomic absorption and
gamma-ray spectrometry were used to analyze the levels of

radionuclides and toxic elements, respectively. Potentially toxic elements (Fe, Pb, Zn, Ni, Cr, Cu and Cd) and associated health risks in surface water and sediment of dams were investigated in this present study. The concentrations of Fe, Pb, Zn, Ni, Cr, Cu and Cd in surface water ranged from 5.430 to 9.700 mg<middle dot>L⁻¹, 0.022 to 0.168, 0.018 to 0.142, 0.065 to 0.366, BDL to 0.0351, BDL to 0.071 and BDL to 0.048 mg<middle dot>L⁻¹, respectively. In the sediments, the concentrations of Fe, Pb, Zn, Cu, Ni, Cd and Cr were of the order of 136.7, 3.41, 3.22, 0.213, 0.182, 0.15 mg<middle dot>L⁻¹ and BDL, respectively. The mean radioactivity rates in the water samples were 1.72, 0.068 and 94.6 Bq<middle dot>L⁻¹ for U-238, Th-232 and K-40, respectively (Tunisia dam), and were 1.9, 0.09 and 131.43 Bq<middle dot>L⁻¹ for U-238, Th-232 and K-40, respectively (Algeria dam). The mean U-238, Th-232 and K-40 radioactivity concentrations measured in the sediment samples were 2.67, 0.18 and 197.87 Bq<middle dot>kg⁽⁻¹⁾, respectively (Tunisian dam), and were 4.34, 0.27 and 287.61 Bq<middle dot>kg⁽⁻¹⁾, respectively (Algeria dam). The activity concentration of K-40 was higher than that of U-238 and Th-232 for the water and sediment samples. The activity concentrations follow the order K-40 > U-238 > Th-232. The cumulative impact of these radio-geochemical elements can cause immediate serious problems in the ecosystem due to their high potential toxicity to the environment and human health in this study area and can be transposable to any other similar region. A good knowledge of monitoring quality and quantity for transboundary water resources and international collaborations are essential to safeguard human health (women's breast cancer, thyroid cancer, neurological impact) and avoid conflicts, especially during climatic upheavals of drought. Thymoquinone extracted from black seed triggers apoptotic
cell death in human colorectal cancer cells via a p53-dependent
mechanism INTERNATIONAL JOURNAL OF ONCOLOGY English

Article anticancer;
blackseed; cell cycle arrest; colon cancer; thymoquinone NIGELLA-
SATIVA; CYTOCHROME-C; G(1) ARREST; P53; MITOCHONDRIA; INHIBITION;
ACTIVATION; EXPRESSION; RELEASE; PROTEIN For centuries, the
black seed (*Nigella sativa*) herb and oil have been used in Asia,
Middle East and Africa to promote health and fight disease.
Thymoquinone (TQ), the most abundant constituent present in black
seed, is a promising dietary chemopreventive agent. We
investigated the effects of thymoquinone (TQ) against HCT-116
human colon cancer cells and attempted to identify its potential
molecular mechanisms of action. We report that TQ inhibits the
growth of colon cancer cells which was correlated with G₁ phase
arrest of the cell cycle. Furthermore, TUNEL staining and flow
cytometry analysis indicate that TQ triggers apoptosis in a dose-
and time-dependent manner. Apoptosis induction by TQ was
associated with a 2.5-4.5-fold increase in mRNA expression of p53
and the downstream p53 target gene, p21(WAF1). Simultaneously, we
found a marked increase in p53 and p21(WAF1) protein levels but a
significant inhibition of anti-apoptotic Bcl-2 protein. Co-
incubation with pifithrin- α . (PFT- α), a specific inhibitor
of p53, restored Bcl-2, p53 and p21WAF1 levels to the untreated
control and suppressed TQ-induced cell cycle arrest and apoptosis.
p53-null HCT-116 cells were less sensitive to TQ-induced growth
arrest and apoptosis. These results indicate that TQ is
antineoplastic and pro-apoptotic against colon cancer cell line
HCT116. The apoptotic effects of TQ are modulated by Bcl-2 protein
and are linked to and dependent on p53. Our data support the
potential for using the agent TQ for the treatment of colon
cancer. Amer Univ Beirut, Dept Biol, Beirut, Lebanon; Otto Von

Shihi, A; Al Lawati, A; Al Kharousi, I Rear seat belt
use as an indicator of safe road behaviour in a rapidly developing
country JOURNAL OF THE ROYAL SOCIETY FOR THE PROMOTION OF
HEALTH English Article

developing countries; Middle East; Oman; road traffic
accidents; seat belts SAUDI-ARABIA; INJURIES; EPIDEMIOLOGY

Injuries from road traffic accidents are set to become the second highest cause of disability-adjusted life years lost in developing countries by 2020. The number of injuries and deaths are disproportionately high in low income countries, which account for only 40% of all motor vehicles. Human behaviour is thought to be a major factor in most accidents. In Oman wearing a seat belt is compulsory in the front seats but not in the rear. Wearing a seat belt can reduce the severity of injuries when sitting in rear seats. This study examines the use of seat belts in cars entering a university and hospital campus in Oman to determine the degree of seat belt wearing in the rear. At peak times on a selected day, cars were stopped at the university's entrance barrier. The type of driver was identified - student, employee, hospital patient or visitor - and the degree of seat belt wearing among driver and passengers was noted. A total of 1,066 cars were stopped. Of this total, 90.1% of drivers and 80.9% of front seat passengers were wearing a restraint complying with local traffic regulations. However, only 1.4% of back seat passengers wore a seat belt. Only 3.7% of children under the age of five were restrained in a child seat and only 16.7% of five- to 12-year-olds were strapped in. A third (34.6%) of under-fives were sitting in the front seat. In cars with child occupants, 40% of the time parents wore seat belts but the children did not. Occupants conformed to the law but behaviour indicated a lack of awareness of the dangers of not wearing seat belts, especially towards children. Traffic regulations need to be updated and the public educated about the need to wear seat belts. Health agencies could be more active in educating the public about road safety behaviour and should also be involved in the overall strategy to reduce injuries and deaths.

Local Burden Dis Diarrhoea
Mapping geographical inequalities in oral rehydration
therapy coverage in low-income and middle-income countries, 2000-
17 LANCET GLOBAL HEALTH English Article

DIARRHEAL DISEASE; CHILDREN;
CHOLERA; AFRICA; MORBIDITY; MORTALITY; DEATHS; ZINC

Background Oral rehydration solution (ORS) is a form of oral rehydration therapy (ORT) for diarrhoea that has the potential to drastically reduce child mortality; yet, according to UNICEF estimates, less than half of children younger than 5 years with diarrhoea in low-income and middle-income countries (LMICs) received ORS in 2016. A variety of recommended home fluids (RHF) exist as alternative forms of ORT; however, it is unclear whether RHF prevent child mortality. Previous studies have shown considerable variation between countries in ORS and RHF use, but subnational variation is unknown. This study aims to produce high-resolution geospatial estimates of relative and absolute coverage of ORS, RHF, and ORT (use of either ORS or RHF) in LMICs. Methods We used a Bayesian geostatistical model including 15 spatial covariates and data from 385 household surveys across 94 LMICs to estimate annual proportions of children younger than 5 years of age with diarrhoea who received ORS or RHF (or both) on continuous continent-wide surfaces in 2000-17, and aggregated results to policy-relevant administrative units. Additionally, we analysed geographical inequality in coverage across administrative units and estimated the number of diarrhoeal deaths averted by increased coverage over the study period. Uncertainty in the mean coverage estimates was calculated by taking 250 draws from the posterior joint distribution of the model and creating uncertainty intervals (UIs) with the 2 center dot 5th and 97 center dot 5th percentiles of those 250 draws. Findings While ORS use among children with diarrhoea increased in some countries from 2000 to 2017, coverage remained below 50% in the majority (62 center dot 6%; 12 417 of 19 823) of second administrative-level units and an estimated 6 519 000 children (95% UI 5 254 000-7 733 000) with diarrhoea were not treated with any form of ORT in 2017. Increases in ORS use corresponded with declines in RHF in many locations, resulting in relatively constant overall ORT coverage from 2000 to 2017. Although ORS was uniformly distributed subnationally in some countries, within-country geographical inequalities persisted in others; 11 countries had at least a 50% difference in one of their units compared with the country mean. Increases in ORS use over time were correlated with declines in RHF use and in diarrhoeal mortality in many locations, and an estimated 52 230 diarrhoeal deaths (36 910-68 860) were averted by scaling up of ORS coverage between 2000 and 2017. Finally, we identified key subnational areas in Colombia, Nigeria, and Sudan as examples of where

diarrhoeal mortality remains higher than average, while ORS coverage remains lower than average. Interpretation To our knowledge, this study is the first to produce and map subnational estimates of ORS, RHF, and ORT coverage and attributable child diarrhoeal deaths across LMICs from 2000 to 2017, allowing for tracking progress over time. Our novel results, combined with detailed subnational estimates of diarrhoeal morbidity and mortality, can support subnational needs assessments aimed at furthering policy makers' understanding of within-country disparities. Over 50 years after the discovery that led to this simple, cheap, and life-saving therapy, large gains in reducing mortality could still be made by reducing geographical inequalities in ORS coverage. J Krishnan, K; Thomas, A Krishnan, Kavita;
Thomas, Antony Correlation of Cervical Cytology With
High-Risk HPV Molecular Diagnosis, Genotypes, and Histopathology-A
Four Year Study From the UAEDIAGNOSTIC CYTOPATHOLOGY
English Article cervical
cytology; HPV; ASCUS; genotype HUMAN-PAPILLOMAVIRUS GENOTYPES;
INTRAEPITHELIAL NEOPLASIA; YOUNG-WOMEN; PREVALENCE; CANCER;
LESIONS; INFECTION; GRADE; COLPOSCOPY; TIME Background: Cervical
cancer is one of the most common cancers among women in the world
and in the Middle East. Its prevention and screening strategies
assume great importance especially in view of the ability to
identify the illness at an early stage and disrupt its progression
toward neoplasia. Cervical cancer screening program of our center
in UAE as well as this study is oriented in this direction.
Methods: Cervical cytology data encompassing 4 years (20112014)
was compiled and analyzed for 14,950 cases to assess the abnormal
smear reporting pattern, correlation with biopsy histopathology,
HPV high-risk screening data, and HPV genotype prevalence among
patients with abnormal smear test, as well as in relation to the
respective nationalities of patients. Results: Abnormal smear
rates as well as HPV high-risk positivity correlated well with
established data. Cytology-histology correlation was good. HPV
high-risk type 16 was the commonest, type 18 which is the second
common type worldwide was less frequently detected, several other
high risk subtypes such as 51, 31 as well as rare types such as
66, 56, and 59 were detected in a significant number of patients.
Conclusion: Assessment of cervical cytology reporting pattern,
correlation of cervical cytology with HPV molecular diagnosis, and
biopsy histopathology is a useful way to audit our work and a good

quality control practice. Higher prevalence of HPV HR types such as type 51, 31 as well as 66, 56, and 59 found in the present as well as many similar other studies apart from the commonest subtype 16 may imply necessity for development of more targeted and multivalent anti-HPV vaccines for protection of women in our region. HPV genotypes correlation with the nationalities of patients is useful from an epidemiological standpoint to plan preventive strategies. (C) 2015 Wiley Periodicals, Inc.

The Life and Works of

Sadid al-Din Kazeroni: An Iranian Physician and Anatomist

MIDDLE EAST JOURNAL OF CANCER

English

Article

Sadid al-Din

Kazeroni; Breast cancer; Anatomical illustration; Al-Mughni;

Persian medicine

Background: One of the great physicians in

Iran who had expertise in medicine, surgery, and pharmacy was

Sadid al-Din Kazeroni. He was a 14th century physician. No

information is available on his birth and death - only "Al-

Mughni", a book, has been left to make him famous in surgical and

medical knowledge. Methods: We used desk and historical research

methods in this research, with a historical approach. This

commonly used research method in human sciences was used to

criticize and study the birthplace and works of Sadid al-Din

Kazeroni. Results and Conclusion: Sadid al-Din Kazeroni discussed

the exact issues in the field of anatomy, surgery, and gynecology.

He was fluent in pharmacology. In his pharmacology book, for the

first time, he named drugs considered necessary before and after

surgery. In this study, we reviewed the biography and introduction

of the works and reviewed "Al-Mughni", a book on breast cancer.

R.; Steck, Susan E. Inflammatory potential of diet
and risk of pancreatic cancer in the Prostate, Lung, Colorectal
and Ovarian (PLCO) Cancer Screening Trial INTERNATIONAL JOURNAL
OF CANCER English Article
dietary patterns; dietary inflammatory index;
incidence; pancreatic cancer; cohort study MEDITERRANEAN DIET;
INDEX; METAANALYSIS; ASSOCIATION; VALIDATION; SCORE
Inflammation plays a central role in pancreatic cancer
etiology and can be modulated by diet. We aimed to examine the
association between the inflammatory potential of diet, assessed
with the Dietary Inflammatory Index (DII (R)), and pancreatic
cancer risk in the Prostate, Lung, Colorectal and Ovarian Cancer
Screening Trial prospective cohort. Our study included 101,449
participants aged 52-78 years at baseline who completed both
baseline questionnaire and a diet history questionnaire. Energy-
adjusted DII (E-DII) scores were computed based on food and
supplement intake. Cox proportional hazards models and time
dependent Cox models were used to estimate hazard ratios (HRs) and
95% confidence intervals (CIs) with participants in the lowest E-
DII quintile (most anti-inflammatory scores) as referent. After a
median 8.5 years of follow-up, 328 pancreatic cancer cases were
identified. E-DII scores were not associated with pancreatic
cancer risk in the multivariable model (HRQ5vsQ1 = 0.94; 95% CI =
0.66-1.35; p-trend = 0.43). Time significantly modified the
association (p-interaction = 0.01). During follow up <4 years,
there was suggestive evidence of an inverse association between E-
DII and pancreatic cancer (HRQ5vsQ1 = 0.60; 95% CI = 0.35-1.02; p-
trend = 0.20) while there was a significant positive trend in the
follow up >= 4 years (HRQ5vsQ1 = 1.31; 95% CI = 0.83-2.08; p-trend
= 0.03). Similar results were observed for E-DII from food only.
Our study does not support an association between inflammatory
potential of diet and pancreatic cancer risk; however,
heterogeneous results were obtained with different follow-up
times. These divergent associations may result from the influences
of undetected disease in the short-term. [Zheng, Jiali;

Isolation and Evaluation of Specific Human Recombinant
Antibodies from a Phage Display Library against HER3 Cancer
Signaling Antigen MIDDLE EAST JOURNAL OF CANCER
English Article Breast

cancer; HER3; Specific scFvs; Antigen targeting MONOCLONAL-ANTIBODY; BINDING; EXPRESSION; INHIBITORS; RECEPTOR; GROWTH; CELLS; ERBB3 Background: The human epidermal growth factor receptor family comprises four homologous members: EGFR (ErbB1), ErbB2 (HER2), ErbB3 (HER3) and ErbB4 (HER4). This family plays an important role in the signaling pathway and cell proliferation. The heterodimerization of HER2 with HER3 leads to tumor cell proliferation. Monoclonal antibody to the human HER3 receptor blocks HER3 heterodimerization and inhibits the growth of breast cancer cells. Due to their human origin, small size, rapid penetration and high affinity properties, recombinant single chain antibodies (scFv) have been introduced as the most desired agents for cancer immunotherapy. In this study, we use a phage display system to select specific scFvs against HER3 for their use in cancer targeted therapy. Methods: A phage antibody display library of scFv was panned against an immunodominant epitope of HER3. Phage rescue was performed on the library. The supernatant that contained the appropriate scFv (109 PFU/ml) was added to an immunotube which was coated with the peptide. Elution was done using log phase E. coli TG1. The clones were amplified by PCR and DNA fingerprinted to select the specific clones against the epitope. The specificity of the selected antibodies was tested in ELISA. Results: The results represented two predominant patterns with the frequency of 25%. The other patterns showed the frequencies of 5%-10%. scFv1 and scFv2 demonstrated positive ELISA with absorbances of 0.63 and 0.46, respectively while the absorbances of wells without peptide were 0.19 and 0.11, respectively. Conclusion: In this study two specific scFvs were selected against HER3 antigen in a successful panning process. Phage ELISA represented the specific binding of scFvs against HER3. The selected scFvs reacted only with the corresponding peptides. However, no reaction with the other peptides was detected. The selected anti-HER3 scFvs have suggested that these human high affinity and small antibodies that bind specifically to HER3 epitope can be considered in HER3 targeted approaches.

King Saud Univ; Int Canc Res Grp Response to Induction Neoadjuvant Hormonal Therapy Using Upfront 21-Gene Breast Recurrence Score Assay-Results From the SAFIA Phase III Trial JCO GLOBAL ONCOLOGY English Article; Proceedings Paper Annual Scientific Meeting of the American-Society-of-Clinical-Oncology (ASCO) MAY 29-JUN 02, 2020

ELECTR NETWORK Amer Soc Clin Oncol SURGICAL ADJUVANT BREAST; FULVESTRANT 500 MG; ANASTROZOLE 1 MG; 1ST-LINE TREATMENT; CANCER; ESTROGEN; CHEMOTHERAPY; LETROZOLE; COMBINATION; PALBOCICLIBPURPOSE Luminal, human epidermal growth factor receptor 2-negative breast cancer represents the most common subtype of breast malignancies. Neoadjuvant strategies of operable breast cancer are mostly based on chemotherapy, whereas it is not completely understood which patients might benefit from neoadjuvant hormone therapy (NAHT). MATERIALS AND METHODS The SAFIA trial is a prospective multicenter, international, double-blind, neoadjuvant phase III trial, using upfront 21-gene Oncotype DX Breast Recurrence Score assay (recurrence score [RS] < 31) to select operable luminal human epidermal growth factor receptor 2-negative patients, for induction hormonal therapy HT (fulvestrant 500 mg with or without goserelin) before randomly assigning responding patients to fulvestrant 500 mg (with or without goserelin) plus either palbociclib (cyclin-dependent kinase 4/6 inhibitor) or placebo. The objectives of this interim analysis were to assess the feasibility of upfront RS determination on core biopsies in the Middle-East and North Africa region and evaluate the efficacy of induction NAHT in patients with an RS < 31. RESULTS At the time of this interim analysis, 258 patients with relative risk were accrued, including 202 patients (RS < 31% to 78.3%) treated with induction NAHT and 182 patients evaluable so far for response. The feasibility of performing the Oncotype DX assays on core biopsy specimens was optimal in 96.4% of cases. Overall, 93.4% of patients showed hormone sensitivity and no difference in NAHT efficacy was noticed between RS 0-10, 11-25, and 26-30. Interestingly, patients with high RS (26-30) showed a trend toward a higher major response rate (P = .05). CONCLUSION The upfront 21-gene assay performed on biopsies is feasible in our population and has allowed us to select patients with high hormone sensitivity (RS < 31). This approach could be an alternative to upfront surgery without significant risk of progression, particularly during pandemic times. Physical activity, sedentary behaviour, diet, and cancer: an update and emerging new evidence LANCET ONCOLOGY

English Article

TELEVISION VIEWING TIME; NIH-AARP DIET; DOSE-RESPONSE METAANALYSIS; INVASIVE BREAST-CANCER; CAUSE-SPECIFIC MORTALITY; QUALITY-OF-LIFE; PROSTATE-CANCER; COLORECTAL-CANCER; MEDITERRANEAN DIET; VITAMIN-E The lifestyle factors of physical activity, sedentary behaviour, and diet are increasingly being studied for their associations with cancer. Physical activity is inversely associated with and sedentary behaviour is positively (and independently) associated with an increased risk of more than ten types of cancer, including colorectal cancer (and advanced adenomas), endometrial cancers, and breast cancer. The most consistent dietary risk factor for premalignant and invasive breast cancer is alcohol, whether consumed during early or late adult life, even at low levels. Epidemiological studies show that the inclusion of wholegrain, fibre, fruits, and vegetables within diets are associated with reduced cancer risk, with diet during early life (age <8 years) having the strongest apparent association with cancer incidence. However, randomised controlled trials of diet-related factors have not yet shown any conclusive associations between diet and cancer incidence. Obesity is a key contributory factor associated with cancer risk and mortality, including in dose-response associations in endometrial and post-menopausal breast cancer, and in degree and duration of fatty liver disease-related hepatocellular carcinoma. Obesity produces an inflammatory state, characterised by macrophages clustered around enlarged hypertrophied, dead, and dying adipocytes, forming crown-like structures. Increased concentrations of aromatase and interleukin 6 in inflamed breast tissue and an increased number of macrophages, compared with healthy tissue, are also observed in women with normal body mass index, suggesting a metabolic obesity state. Emerging randomised controlled trials of physical activity and dietary factors and mechanistic studies of immunity, inflammation, extracellular matrix mechanics, epigenetic or transcriptional regulation, protein translation, circadian disruption, and interactions of the microbiome with lifestyle factors will be crucial to advance this field. Background: The human papillomavirus (HPV) vaccine has
recently attracted considerable attention in emerging countries,
due to its potential to reduce the impact of HPV-related diseases.
This case study sheds new light about the variety of HTA
arrangements, methods and processes involved in the adoption and
use of HPV vaccines in a selected sample of central, eastern and
southern Europe and Latin America and the Caribbean, all of them
