emerging in the use of HTA. Materials & Methods: A multi-country
case study was designed. Mixed methods, document review, semi-
structured surveys and personal communication with experts, were
used for data collection and triangulation. Results: This study
shows that common elements of good practice exist in the processes
and methods used, with all countries arriving at the same
appraisal recommendations. However, the influence of
sociopolitico-economic factors appears to be determinant on the
final decisions and restrictions to access made. Conclusion: This
case study intends to draw useful lessons for policymakers in
emerging settings interested in the adoption of the HPV vaccine
supported by evidence-informed processes, such as those offered by
institutionalized HTA. Future studies are also recommended to
elucidate the specific roles that social values and uncertainties
play in vaccine decision-making across different societies.

Olea europaea var. *Oleaster* a promising nutritional food with in vitro antioxidant, antiglycation, antidiabetic and antiproliferative effects JOURNAL OF FOOD MEASUREMENT AND CHARACTERIZATION English Article

Olea europaea var; *Oleaster*; Bioactive compounds; Antioxidant activities; Antidiabetic; Antiglycation; Breast cancer; Cytotoxicity GLYCATION END-PRODUCTS; CANCER; FRUIT; OIL

Advanced glycation end products (AGEs) generated from glycation might cause diseases such as diabetes and breast cancer. Antioxidants have an important role in protecting humans against infections and degenerative diseases due to their ability to neutralize AGEs. *Olea europaea* var. *oleaster* (Oeo) is an ancient plant widespread in the Mediterranean basin which is traditionally used as a source of antioxidants. The present research deals with phytochemical screening and the antioxidant properties of both aqueous and methanolic extracts of the Oeo fruit. Additionally, antidiabetic potential (alpha-amylase and alpha-glucosidase inhibitory activities) and inhibitory potential on AGEs formation have been investigated using the methanolic extract of the Oeo (ME-Oeo) fruit. The cytotoxic effect against two human breast cancer cell lines (MDA-MB-468 and MCF-7) was also investigated. Both aqueous and methanolic extracts showed a high phenolic and flavonoid content: by using HPLC-DAD-ESI/MS up to fifteen major compounds were positively identified. The methanolic extract

showed better antioxidant activity than aqueous extract in all tests. Also, the ME-Oeo fruit showed high inhibitory effects on the production of Amadori products and AGEs from albumin in the presence of fructose and a high significant inhibitory effect against alpha-amylase (IC₅₀ = 2.367 mg/mL) and alpha-glucosidase (IC₅₀ = 1.272 mg/mL), respectively. The ME-Oeo fruit showed moderate cytotoxic activity against MDA-MB-468 cell line (IC₅₀ = 35.16 μ g/mL), and MCF-7 cell line (IC₅₀ = 46.75 μ g/mL). These results suggest the possibility of using ME-Oeo fruit as a source of natural bioactive compounds for the prevention of glycation-associated complications in diabetes and in cytotoxicity treatment. N Mahmoud, Ibrahim; Al Eid, Mithaq Mohammed
A.; Mohamed, Meera Ahmed; Aladwani, Ahmad Jihad; El Mustafa El
Amin, Nagwa Human papillomavirus vaccination and Pap
test uptake, awareness, and barriers among young adults in Gulf
Cooperation Council countries: A comparative cross-sectional
survey JOURNAL OF INFECTION AND PUBLIC HEALTH
English Article Cervical
cancer; HPV vaccine; GCC countries; Vaccine uptake HPV
VACCINATION; CERVICAL-CANCER; NORTH-AFRICA; MIDDLE-EAST; WOMEN;
ATTITUDES; KNOWLEDGE Background: Human papillomavirus (HPV)
vaccination and Pap tests are recognized as effective preventive
measures to reduce the incidence of HPV-related diseases among
young adults. The objective of this study was to assess HPV
vaccination and Pap test uptake, awareness, and barriers among
young adults in the Gulf Cooperation Council (GCC) countries,
including Bahrain, Kuwait, Oman, Qatar, the Kingdom of Saudi
Arabia (KSA), and the United Arab Emirates (UAE). Methods: A
comparative cross-sectional study was conducted from January to
April 2024, involving 831 young adults aged 18-39 residing in GCC
countries. The main outcome measures were HPV vaccination and Pap
test uptake rates, awareness of the HPV vaccine and Pap testing,
and barriers to vaccination. Data were collected using online
platforms. The Chi-square test and Fisher's exact test were used
for data analysis. Results: The UAE had the highest vaccination
rate at 18.9% (50/264), followed by Qatar at 5.8% (6/104), and KSA
at 4.6% (10/216), $p < 0.001$. Individuals with health insurance had
higher vaccination rates than those without (11% vs. 5.4%, $p =$
0.006). Awareness of the HPV vaccine was highest in the UAE
(49.6%) and KSA (58.8%), while awareness of Pap smear testing
among females was similarly high in these countries (62.4% and
65.9%, respectively). However, actual Pap smear testing rates were
highest in Bahrain (15.9%) and Qatar (13.4%). The main barriers to
vaccination cited by participants were lack of knowledge (53.6%)
and the absence of medical recommendations (13.2%). Conclusion:
The study's findings suggest the need of targeted educational
campaigns to increase HPV vaccine uptake among both genders and
Pap test participation among females. Additionally, incorporating
HPV screening and vaccination into routine national programs in
GCC countries and emphasising the crucial role of healthcare
providers in influencing vaccination decisions are recommended
strategies. . (c) 2024 The Author(s). Published by Elsevier Ltd on

 Prevalence of genital human papillomavirus among
 Lebanese women EUROPEAN JOURNAL OF GYNAECOLOGICAL ONCOLOGY
 English Article
 human papillomavirus (HPV); pap smear; cervical dysplasia;
 cervical cancer; PCR; Lebanon POLYMERASE-CHAIN-REACTION;
 CERVICAL INTRAEPITHELIAL NEOPLASIA; GENERAL PRIMERS; INFECTION;
 RISK; CANCER; HPV; DETERMINANTS; TYPE-16; GRADE Purpose: The
 purpose of this study was to determine the prevalence of human
 papillomavirus (HPV), and more specifically of HPV 16, in a group
 of Lebanese women. Materials and Methods: Type-specific prevalence
 of cervical HPV and the presence of cytological abnormalities were
 determined in a cohort of Lebanese women. The population included
 1,026 women, 18-76 years, seeking routine gynecological care at a
 tertiary care center. Demographic and behavioral data were
 collected. HPV DNA was detected in cervical scrapes by polymerase
 chain reaction using consensus primers. Cervical cytological
 abnormalities were identified by Papanicolaou (Pap) smears.
 Results: The mean age of our population was 40 +/- 11.3 years.
 General HPV DNA was detected in 50 patients (4.9%). The high-risk
 HPV type 16 DNA was detected in 31 patients (3%). Patients with
 HPV 16 were more likely to have an abnormal pap smear than those
 with negative tests (6.6% vs 1.6%, $p < 0.05$), and more likely, but
 not significantly, to be smokers (21.4% vs 18.4%, $p = 0.5$). The
 age-specific prevalence of HPV increased with age and peaked at
 60-69 years. Conclusions: The prevalence of HPV in this small
 group of Lebanese women is similar to its prevalence in the
 Mediterranean countries. The presence of HPV, its known
 association with the development of cervical neoplasia, and the
 lack of a universal screening program for cervical cancer in our
 country should be used to enforce implementation of proper
 screening programs. Amer Univ Beirut, Med Ctr, Dept Obstet &

Antiproliferative activity against human tumor cell lines
and toxicity test on Mediterranean dietary plants FOOD AND
CHEMICAL TOXICOLOGY English Article

Antiproliferative activity; Human cancer;
Acute toxicity; Bioluminescence test; Phenolic and flavonoid
content; Phytosterols VIBRIO-FISCHERI; NATURAL-PRODUCTS;
PHENOLIC-COMPOUNDS; DRUG DISCOVERY; WASTE-WATER; INHIBITION;
EXTRACTS; GROWTH; PHARMACOGNOSY; CAMPTOTHECIN Sixteen edible
plants from Southern Italy were evaluated for their in vitro
antiproliferative properties, using the sulforodamine B (SRB)
assay, on four human cancer cell lines: breast cancer MCF-7.
prostate cancer LNCaP, amelanotic melanoma C32 and renal
adenocarcinoma ACHN. After 48 h of incubation the most
antiproliferative plant extract was *Cynara cardunculus* ssp.
cardunculus on C32 and ACHN cell lines with IC50 of 21 and 18 μ
g/ml, respectively. *Mentha aquatica* showed a selective
antiproliferative activity on breast cancer while significant
activity was exerted by *Cichorium intybus* on melanoma. These
species contained the highest amount of phenolics. The acute
toxicity of the hydroalcohol extracts from all the plants were
evaluated by using the Microtox acute toxicity test. This
bacterial test measures the decrease in light emission from the
marine luminescent *Vibrio fischeri* bacteria when exposed to
organic extracts. This inhibition test was revealed to be highly
sensitive, cost effective and easy to operate, requiring just 15
min to predict the sample toxicity. All the extracts analyzed
resulted to give values very less than a limit of 20% value,
demonstrating so an irrelevant toxicity for the human health. In
contrast, *Echium vulgare* and *Malva sylvestris* showed
bioluminescence inhibition values of 19.42% and 17.32%,
respectively, just under the established limit. (C) 2008 Elsevier

J Menendez, JA; Vazquez-Martin, A; Oliveras-Ferraros, C; Garcia-Villalba, R; Carrasco-Pancorbo, A; Fernandez-Gutierrez, A; Segura-Carretero, A Menendez, Javier A.; Vazquez-Martin, Alejandro; Oliveras-Ferraros, Cristina; Garcia-Villalba, Rocio; Carrasco-Pancorbo, Alegria; Fernandez-Gutierrez, Alberto; Segura-Carretero, Antonio Analyzing effects of extra-virgin olive oil polyphenols on breast cancer-associated fatty acid synthase protein expression using reverse-phase protein microarrays INTERNATIONAL JOURNAL OF MOLECULAR MEDICINE English Article

olive oil; polyphenols; cancer; fatty acid synthase; human epidermal growth factor receptor 2 PHENOLIC-COMPOUNDS; CAPILLARY-ELECTROPHORESIS; TEA POLYPHENOLS; OLEIC-ACID; CELLS; OVEREXPRESSION; ANTIOXIDANT; INHIBITION; METABOLISM; SUPPRESSION

Inhibitors of fatty acid synthase (FASN), a key enzyme involved in the anabolic conversion of dietary carbohydrates to fat in mammals, are receiving increasingly more attention as they may provide therapeutic moieties for the treatment of human malignancies. Natural compounds, such as the green tea polyphenol epigallocatechin-3-gallate, have been shown to induce anti-cancer effects by suppressing FASN, which may account for the epidemiologically observed inverse correlation between green-tea drinking and cancer risk in Oriental populations. Since extra-virgin olive oil (EVOO)-derived phenolics have been suggested to possess biological activities that may explain the health-promoting effects of the 'Mediterranean diet', we evaluated their effects on the expression of FASN protein in human breast epithelial cell lines. First, we developed a reverse phase protein microspot array (RPPA) capable of rapidly assessing the relative amount of FASN protein in whole lysates from cultured human cells. Then we tested the effects of phenolic fractions from EVOO and its main constituents including single phenols (i.e. tyrosol, hydroxytyrosol, vanillin), phenolic acids (i.e. caffeic acid, p-coumaric acid, vanillic acid, ferulic acid, elenolic acid), lignans (i.e. 1-[+]-pinoresinol, 1-[+]-acetoxy-pinoresinol), flavonoids (i.e. apigenin, luteolin), or secoiridoids (i.e. deacetoxyoleuropein aglycone, ligstroside aglycone, oleuropein glycoside, oleuropein aglycone) on FASN protein expression. EVOO polyphenols lignans, flavonoids and secoiridoids were found to drastically suppress FASN protein expression in HER2 gene-amplified SKBR3 breast cancer cells. Equivalent results were observed in MCF-7 cells engineered to overexpress the HER2 tyrosine kinase receptor, a well-characterized up-regulator of FASN expression in aggressive sub-types of cancer cells. EVOO-derived lignans, flavonoids and secoiridoids were significantly more effective than the mono-HER2 inhibitor trastuzumab (similar to 50% reduction) and as effective as the dual HER1/HER2 tyrosine kinase inhibitor lapatinib ($\geq 95\%$ reduction) at suppressing high-levels of FASN protein in HER2-overexpressing SKBR3 and MCF-7/HER2 cells. EVOO single phenols and phenolic acids failed to modulate FASN expression in SKBR3 and MCF-7/HER2 cells. These findings reveal for the first time that phenolic fractions, directly extracted from EVOO, may induce anti-cancer effects by suppressing the expression of the lipogenic enzyme FASN in HER2-overexpressing breast carcinoma cells, thus offering a previously unrecognized mechanism for EVOO-related cancer preventive effects.

Parents' Diet Quality and Physical Activity Are Associated with Lifestyle in Spanish Children and Adolescents: The PASOS Study NUTRIENTS English Article

Mediterranean Diet; physical activity; exercise; lifestyle; kids; teenagers; PASOS MEDITERRANEAN DIET; LOW-INCOME; VALIDITY; HEALTH; INDEX; OVERWEIGHT; ADHERENCE; OBESITY; SLEEP; YOUTH Background: Non-communicable chronic diseases are associated with a low-quality diet, low physical activity, and sedentary behavior. Objective: To assess how parents' diet and physical activity habits were associated with their offsprings' lifestyles. Study design: A cross-sectional analysis of 8-16-year-old children and adolescents (n = 2539; 51.9% girls) was carried out within the frame of the first edition of the Physical Activity, Sedentarism, Lifestyles, and Obesity in Spanish Youth study (PASOS-2019). Data on adherence to the Mediterranean Diet (MedDiet), daily moderate-

vigorous physical activity (MVPA), and screen time per day (television, computer, video games, and mobile phone) were collected from children and adolescents, and data on parents' diet quality and physical activity were compiled. Logistic regression models were used to assess the association between parents' lifestyles and those of children and adolescents. Results: High diet quality of parents was associated with higher adherence to the MedDiet of children and adolescents, as well as high consumption of fruit, vegetables, fish, nuts, and legumes. The high physical activity level of parents was associated with the low consumption of fast foods, sweets, and candies in children and adolescents. Children with high levels of physical activity were those whose parents showed better diet quality and physical activity levels. Conclusions: Parents' high diet quality and physical activity were associated with healthy lifestyles, higher adherence to the MedDiet, and physical activity of their offspring, mainly in adolescents. Perceptions, Knowledge and Attitudes among Young Adults
about Prevention of HPV Infection and Immunization HEALTHCARE
English Article HPV
vaccine; human papilloma virus; attitudes; cervical cancer;
prevention; knowledge; perception HUMAN-PAPILLOMAVIRUS HPV;
CERVICAL-CANCER PREVENTION; FEMALE STUDENTS; VACCINATION COVERAGE;
ADOLESCENTS; AWARENESS; BEHAVIORS; EDUCATION; GREECE; WOMEN

Introduction: Human papilloma virus (HPV) is one of the most common sexually transmitted infections and is widely known as the main causative agent for cervical cancer. The aim of this study was to investigate the perceptions, knowledge and attitudes of young Greek adults concerning prevention of HPV infection and HPV immunization. Material and Methods: This constitutes a cross-sectional online survey. A convenience sample of young Greek adults (n = 883) residing in Greece, aged 17 to more than 35 years was surveyed from December 2020 to March 2021. Two validated questionnaires were used to collect data. Results: Participants demonstrated moderate knowledge about HPV infection and vaccination, with a mean knowledge score of 53.26 (SD +/- 20.65) and 38.92 (SD +/- 17.58), respectively. Cronbach's alpha value was 0.77 and 0.80. Female participants were better informed than males. Approximately 52.3% of respondents had been vaccinated and 65.5% were willing to get vaccinated in the future. Vaccination rate was significantly associated with gender (OR = 11.99; 99% CI = 6.59-21.84), knowledge about the HPV vaccine (OR = 1.04; 99% CI = 1.03-1.04) and age (OR = 0.07; 99% CI = 0.03-0.15). Reasons for vaccine refusal were insufficient information (36.8%) and fear of side effects (19%). Correlates of positive vaccination intention

were knowledge about HPV (OR = 1.02; 99% CI = 1.01-1.02).
 Conclusions: The findings suggest that the Greek government's continuing HPV promotion efforts and education on the risks of HPV infection among young people are likely to increase vaccination acceptance among this group. J Wisitpongpan, P; Suphrom, N; Potup, P; Nuengchamnong, N; Calder, PC; Usuwanthim, K Wisitpongpan, Prapakorn; Suphrom, Nungruthai; Potup, Pachuen; Nuengchamnong, Nitra; Calder, Philip C.; Usuwanthim, Kanchana In Vitro Bioassay-Guided Identification of Anticancer Properties from Moringa oleifera Lam. Leaf against the MDA-MB-231 Cell Line
 PHARMACEUTICALS English Article

Moringa oleifera; triple negative breast cancer; MDA-MB-231; oleamide; 7-octenoic acid; 1-phenyl-2-pentanol; LC-ESI-QTOF-MS/MS ETHANOLIC EXTRACT; OLEAMIDE; LEAVES; MECHANISMS; GLYCOSIDES; APOPTOSIS; NECROSIS; PLANTS; FAMILY

Moringa oleifera Lam. (MO) is a medicinal plant distributed across the Middle East, Asia, and Africa. MO has been used in the traditional treatment of various diseases including cancer. This study aimed to perform bioassay-guided fractionation and identification of bioactive compounds from MO leaf against MDA-MB-231 breast cancer cells. MO leaf was sequentially extracted with hexane, ethyl acetate (EtOAc), and ethanol. The most effective extract was subjected to fractionation. MO extract and its derived fractions were continuously screened for anti-cancer activities.

The strongest fraction was selected for re-fractionation and identification of bioactive compounds using LC-ESI-QTOF-MS/MS analysis. The best anticancer activities were related to the fraction no. 7-derived crude EtOAc extract. This fraction significantly reduced cell viability and clonogenic growth and increased cells apoptosis. Moreover, sub-fraction no. 7.7-derived fraction no. 7 was selected for the identification of bioactive compounds. There were 10 candidate compounds tentatively identified by LC-ESI-QTOF-MS. Three of identified compounds (7-octenoic acid, oleamide, and 1-phenyl-2-pentanol) showed anticancer activities by inducing cell cycle arrest and triggering apoptosis through suppressed Bcl-2 expression which subsequently promotes activation of caspase 3, indicators for the apoptosis pathway. This study identified 10 candidate compounds that may have potential in the field of anticancer substances.

Under which conditions would a wide support be likely
for a Multilateral Environmental Agreement for pollinator
protection?ENVIRONMENTAL SCIENCE & POLICY English

Article Cost-effective;

Cross-sector; Pollinators; Education; Policymaker SERVICES;
CONSERVATION; LANDSCAPES; ENHANCE The Nagoya Protocol (2010)
demonstrated that Multilateral Environmental Agreements (MEA) are
still achievable. Pollination services are essential for
biodiversity, agriculture, ecosystem services and human wellbeing,

but in jeopardy as The Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) confirmed. In 2016, thirteen mostly European countries established the Coalition of the Willing on Pollinators. This group of forerunners increased to twentyone members. Recently, the European Union (EU) decided to join in 2018. What would be necessary to move forward towards a Multilateral Environmental Agreement for pollinator protection during the next three or four Conferences of the Parties (COP) of the Convention for Biological Diversity (CBD)? Current approaches for pollinator protection mostly require subsidies or donations, they are not scalable and might limit the number of countries promoting a multilateral agreement. This paper suggests a mix of four strategies and low-cost policy measures across sectors. They would be affordable even for Low Income Countries (LIC), but require addressing certain research gaps to set the stage for policymakers.

J Cosma, C; Maia, C; Khan, N; Infantino, M; Del Riccio, M Cosma, Claudia; Maia, Carla; Khan, Nushrat; Infantino, Maria; Del Riccio, Marco Leishmaniasis in Humans and Animals: A One Health Approach for Surveillance, Prevention and Control in a Changing World TROPICAL MEDICINE AND INFECTIOUS DISEASE English Article

neglected tropical diseases; vector-borne diseases; sandflies; climate change; urbanisation; migration; globalisation VISCERAL LEISHMANIASIS; PHLEBOTOMINE SANDFLIES; CANINE LEISHMANIASIS; EUROPE; INFANTUM; DOGS; INFECTION; DISEASES; CLIMATE; SPREAD Leishmaniasis is classified as a neglected tropical disease (NTD), caused by protozoan parasites of the genus Leishmania, which are transmitted to humans and other animals through the bite of infected female phlebotomine sandflies. There are three forms of the disease: cutaneous leishmaniasis (CL) manifested by ulcers and scars; systemic or visceral leishmaniasis (VL), which can lead to life-threatening complications if left untreated; and mucocutaneous leishmaniasis (MCL), which can destroy the mucous membranes of the nose, mouth and throat. Human

leishmaniasis is endemic in many countries across Africa, Asia, Southern Europe, the Middle East, and Central and South America. The interconnection of environmental, animal and human health underlies the spread of the *Leishmania* parasite. Environmental disruptions, such as climate change, deforestation or urbanisation, but also globalisation and migration, significantly affect the distribution and abundance of sand fly vectors and reservoir hosts. Climate change alters the breeding patterns of sandflies and expands their geographic range; deforestation and misuse of large areas disrupt ecosystems, leading to increased human-vector contact; and urbanisation increases the potential for contact between parties, particularly in densely populated areas. Migration of humans and animals, either through natural migration or, for example, the pet trade and breeding, can facilitate the spread of *Leishmania* parasites. In addition, socio-economic factors, including poverty and lack of access to healthcare, increase the burden of leishmaniasis in vulnerable populations. Due to this multitude of reasons, the geographic distribution of sandflies has expanded to higher latitudes and altitudes in recent years, with a consequent increase in disease burden. Indeed, despite ongoing challenges in the surveillance systems, data from the last available year have shown an increase in many cases in both humans and dogs. This perspective explores the interconnected factors influencing the spread of leishmaniasis worldwide and the epidemiology of the disease. In addition, it illustrates the importance of integrated strategies in a One Health approach: surveillance, prevention and control of vectors, animals and humans.

Al Alawi, Salma; Al Zaabi, Omar; Heffernan, Margaret
E.; Arulappan, Judie; Al Hasani, Noora; Al Baluchi, Munira; Al
Mamari, Alia; Al Saadi, Amani Knowledge, attitudes

and acceptance toward Human papillomavirus (HPV) vaccination:

Perspectives of Muslim women and men VACCINE

English Article Cervical

cancer; Human papillomavirus; HPV vaccine; HPV knowledge;

Attitudes; Muslim UNIVERSITY-STUDENTS; YOUNG-WOMEN; MIDDLE-

EAST; ACCEPTABILITY; PREVALENCE; INFECTION; AWARENESS; IMPACT;

VIRUS Objectives: Human papillomavirus (HPV) infection is the

leading risk factor for the development of anogenital cancers.

Most Arab countries lack both HPV education and national HPV

vaccination pro-grams. The objective of this study was to assess

knowledge, attitudes, and acceptance toward HPV vac-cination in

men and women from Oman, a country in the Middle Eastern North

Africa region. Methods: This cross-sectional quantitative study

used convenience sampling to recruit male and female participants,

aged 18 years and above from all 11 governorates of Oman to

complete a validated self-administered questionnaire online in the

Arabic language. The questionnaire comprised five sections, with a

total of 32 questions. The questionnaire, including Arabic and

English versions, was content val-idated and piloted. Results: A

total of 1403 participants, including 952 parents and 369

healthcare providers, completed the survey. The results showed a

lack of knowledge regarding HPV infection and vaccines, including

among healthcare providers. Less than a quarter of the

participants had heard of HPV infection, with digital sources of

information being the most common. Factors such as being a woman

or a healthcare provider or completing higher levels of education

were independently and significantly positively association with

HPV awareness (p < 0.001). The majority of the participants lacked

vaccine safety knowledge, had concerns about the vaccine's side effects, and sought reassurance of its protection against HPV infection (62%, 71.5%, and 84.6%, respectively). Nevertheless, nearly two-thirds of the participants agreed to take the HPV vaccine, with support for both boys and girls being vaccinated. There was almost universal agreement among the participants regarding the need for parental and adolescent HPV educational programs. Conclusion: Omani women and men showed a high level of acceptance and favorable attitude toward HPV vaccination. The study findings support future efforts to implement school and public-level HPV education and a national HPV vaccination program in Oman. (c) 2023 Elsevier Ltd. All rights reserved. J Nasser, K; Moulton, LH Nasser, K
 Kiumarss; Moulton, Lawrence H. Patterns of Death in
 the First and Second Generation Immigrants from Selected Middle
 Eastern Countries in California JOURNAL OF IMMIGRANT AND
 MINORITY HEALTH English Article
 Migrant studies; Middle East; Ethnic groups;
 Mortality; Proportional odds ratio CANCER-MORTALITY; DISEASE
 MORTALITY; WHITE IMMIGRANTS; FOREIGN-BORN; ALL-CAUSE; MIGRANTS;
 JAPANESE; 1ST-GENERATION; GENERATION; SWEDEN Migrant studies in
 the United States (US) have rarely covered the Middle Eastern
 population (ME), and have never distinguished the first and second
 generations born in the US. This study aims to describe the
 mortality patterns of ME immigrants by origin, acculturation, and
 generation. Death certificates issued from 1997 through 2004 were
 used to calculate, for Middle Eastern immigrants, the proportional
 odds ratios (POR) for major causes of death, with comparison to

non-Hispanic Whites born in the US to US-born parents. First generation immigrants had higher odds for colorectal cancers, diabetes, and diseases of the heart, while their odds for chronic obstructive pulmonary disease (COPD) and suicide were lower. Men had higher odds for all cancers combined, cancers of the lymphatics, and pancreas. Women had lower odds for lung cancer, and dementia, and higher odds for breast cancer. The second generation men had higher odds for all cancers combined, and diseases of the heart, whereas women had lower odds for lung cancer and cerebrovascular accidents. Higher odds for colorectal cancers and lower odds for COPD were noted in both sexes. Some of the observed differences may be based on ethnic characteristics, including genetic makeup, early exposures, and culturally determined values. Time since immigration is associated with convergence of most odds to that of the native population.

 Ozek, Nihal Simsek; Tuna, Serkan; Erson-Bensan, A. Elif; Severcan, Feride Characterization of microRNA-125b expression in MCF7 breast cancer cells by ATR-FTIR spectroscopy ANALYST English Article
 TRANSFORM-INFRARED-SPECTROSCOPY; INDUCED LIPID-PEROXIDATION; UNSATURATED FATTY-ACIDS; IR SPECTROSCOPY; MEMBRANE FLUIDITY; MODEL MEMBRANES; HUMAN TISSUES; ANIMAL-MODEL; LOW-DENSITY; K562 CELLS MicroRNAs (miRNAs), are similar to 22 nucleotides long, non-coding RNAs that control gene expression post-transcriptionally by binding to their target mRNA's 3'UTRs (untranslated regions). Due to their roles in various important regulatory processes and pathways, miRNAs have been implicated in disease mechanisms such as tumorigenesis when their expression is deregulated. To date, a significant number of miRNAs and their target messenger RNAs (mRNAs) have been identified and verified. It is generally accepted that miRNAs can potentially bind to many mRNAs, which brings the requirement of validation of these interactions. While understanding that such individual interactions is crucial to delineate the role of a specific miRNA, we took a holistic approach and analyzed global changes in the cell due to expression of a miRNA in a model cell line system. Our model consisted of MCF7 cells stably transfected

with miR-125b (MCF7-125b) and empty vector (MCF7-EV). MiR-125b is one of the known down-regulated miRNAs in breast cancers. In this study we examined the global structural changes in MCF7 cells lacking and expressing miR-125b by Attenuated Total Reflectance Fourier Transform Infrared (ATR-FTIR) Spectroscopy and investigated the dynamic changes by more sensitive spin-labelling Electron Spin Resonance (ESR) spectroscopy. Our results revealed less RNA, protein, lipid, and glycogen content in MCF7-125b compared to MCF7-EV cells. Membrane fluidity and proliferation rate were shown to be lower in MCF7-125b cells. Based on these changes, MCF7-125b and MCF7-EV cells were discriminated successfully by cluster analysis. Here, we provide a novel means to understand the global effects of miRNAs in cells. Potential applications of this approach are not only limited to research purposes. Such a strategy is also promising to pioneer the development of future diagnostic tools for deregulated miRNA expression in patient samples. [Ozek, Nihal Simsek; Tuna, Serkan; Erson-Bensan, A. Nutrition literacy predicts adherence to healthy/unhealthy diet patterns in adults with a nutrition-related chronic condition PUBLIC HEALTH NUTRITION

English Article Nutrition literacy; Diet pattern analysis; Western diet; Mediterranean diet; Principal covariates regression; Principal components analysis

REDUCED RANK REGRESSION; HEALTH LITERACY; PRICE DISCOUNTS; RELIABLE MEASURE; GROCERY STORE; SELF-EFFICACY; FOOD; EDUCATION; NUMERACY; OUTCOMES Objective: To describe the relationship between adherence to distinct dietary patterns and nutrition literacy. Design: We identified distinct dietary patterns using principal covariates regression (PCovR) and principal components analysis (PCA) from the Diet History Questionnaire II. Nutrition literacy was assessed using the Nutrition Literacy Assessment Instrument (NLit). Cross-sectional relationships between dietary pattern adherence and global and domain-specific NLit scores were tested by multiple linear regression. Mean differences in diet

pattern adherence among three predefined nutrition literacy performance categories were tested by ANOVA. Setting: Metropolitan Kansas City, USA. Participants: Adults (n 386) with at least one of four diet-related diseases. Results: Three diet patterns of interest were derived: a PCovR prudent pattern and PCA-derived Western and Mediterranean patterns. After controlling for age, sex, BMI, race, household income, education level and diabetes status, PCovR prudent pattern adherence positively related to global NLit score ($P < 0.001$, $\beta = 0.36$), indicating more intake of prudent diet foods with improved nutrition literacy. Validating the PCovR findings, PCA Western pattern adherence inversely related to global NLit ($P = 0.003$, $\beta = -0.13$) while PCA Mediterranean pattern positively related to global NLit ($P = 0.02$, $\beta = 0.12$). Using predefined cut points, those with poor nutrition literacy consumed more foods associated with the Western diet (fried foods, sugar-sweetened beverages, red meat, processed foods) while those with good nutrition literacy consumed more foods associated with prudent and Mediterranean diets (vegetables, olive oil, nuts). Conclusions: Nutrition literacy predicted adherence to healthy/unhealthy diet patterns. These findings warrant future research to determine if improving nutrition literacy effectively improves eating patterns. [Taylor,

Tavoni, Alessandro Past and present biophysical
redundancy of countries as a buffer to changes in food supply
ENVIRONMENTAL RESEARCH LETTERS English
Article redundancy; water;
spare land; yield gap; productivity; resilience GLOBAL WATER;
FRESH-WATER; BIODIVERSITY; RESILIENCE; SECURITY; IMPACTSSpatially
diverse trends in population growth, climate change,
industrialization, urbanization and economic development are
expected to change future food supply and demand. These changes
may affect the suitability of land for food production, implying
elevated risks especially for resource-constrained, food-importing
countries. We present the evolution of biophysical redundancy for
agricultural production at country level, from 1992 to 2012.
Biophysical redundancy, defined as unused biotic and abiotic
environmental resources, is represented by the potential food
production of 'spare land', available water resources (i.e., not
already used for human activities), as well as production
increases through yield gap closure on cultivated areas and
potential agricultural areas. In 2012, the biophysical redundancy
of 75 (48) countries, mainly in North Africa, Western Europe, the
Middle East and Asia, was insufficient to produce the caloric
nutritional needs for at least 50% (25%) of their population
during a year. Biophysical redundancy has decreased in the last
two decades in 102 out of 155 countries, 11 of these went from
high to limited redundancy, and nine of these from limited to very
low redundancy. Although the variability of the drivers of change
across different countries is high, improvements in yield and
population growth have a clear impact on the decreases of
redundancy towards the very low redundancy category. We took a
more detailed look at countries classified as 'Low Income
Economies (LIEs)' since they are particularly vulnerable to
domestic or external food supply changes, due to their limited
capacity to offset for food supply decreases with higher
purchasing power on the international market. Currently, nine LIEs
have limited or very low biophysical redundancy. Many of these

showed a decrease in redundancy over the last two decades, which is not always linked with improvements in per capita food availability. PALB2 germline
mutations in a large cohort of Middle Eastern breast-ovarian
cancer patients SCIENTIFIC REPORTS

Article

English

FANCONI-ANEMIA;

PANEL; GENE The PALB2 gene is a breast cancer (BC) and ovarian
cancer (OC) predisposition gene involved in the homologous
recombination repair pathway. However, the prevalence and
clinicopathological association of PALB2 pathogenic/likely
pathogenic (PV/LPV) variants in Middle East is still not fully
explored. Total 918 BC/OC patients from Saudi Arabia were selected
for PALB2 mutations screening using capture sequencing technology.
Five heterozygous PVs or LPVs were identified in six cases,
accounting for 0.65% (6/918) of entire cohort. Two cases (33.3%)
harbored PVs and four cases (66.7%) carried LPVs. Four PVs/LPVs
(80%) were frameshift along with one novel splicing LPV (c.2835-
2_2835-1delinsTT). One recurrent LPV (c.3425delT: p.L1142fs) was
identified in two cases. All six affected carriers have breast
cancer diagnosis with median age of 39.5 years (range 34-49
years). Only two cases (33%) have documented family history of
cancer. Breast cancer phenotype was invasive ductal unilateral
cancer in all cases with 66.7% of hormone receptor positive and
16% of triple negative tumors. Germline PVs/LPVs in the PALB2 gene
were observed in low frequency of 0.65% in Saudi BC and/or OC. Our
study confirms one recurrent LPV and one novel LPV in Saudi breast
cancer patients. [Siraj, Abdul K. K.; Bu, Rong; Parvathareddy,

tabAnti-HER2 (erbB-2) oncogene effects of phenolic compounds
 directly isolated from commercial Extra-Virgin Olive Oil (EVOO)

BMC CANCER English Article
 MONOUNSATURATED FATTY-ACID; BREAST-CANCER
 CELLS; APIGENIN INDUCES APOPTOSIS; OLEIC-ACID; TRASTUZUMAB
 HERCEPTIN(TM); CAPILLARY-ELECTROPHORESIS; BIOLOGICAL-ACTIVITIES;
 EXPRESSION; ANTIOXIDANT; COMPONENTS Background: The effects of
 the olive oil-rich Mediterranean diet on breast cancer risk might
 be underestimated when HER2 (ERBB2) oncogene-positive and HER2-
 negative breast carcinomas are considered together. We here
 investigated the anti-HER2 effects of phenolic fractions directly
 extracted from Extra Virgin Olive Oil (EVOO) in cultured human
 breast cancer cell lines. Methods: Solid phase extraction followed
 by semi-preparative high-performance liquid chromatography (HPLC)
 was used to isolate phenolic fractions from commercial EVOO.
 Analytical capillary electrophoresis coupled to mass spectrometry
 was performed to check for the composition and to confirm the
 identity of the isolated fractions. EVOO polyphenolic fractions
 were tested on their tumoricidal ability against HER2-negative and
 HER2-positive breast cancer in vitro models using MTT, crystal
 violet staining, and Cell Death ELISA assays. The effects of EVOO
 polyphenolic fractions on the expression and activation status of
 HER2 oncoprotein were evaluated using HER2-specific ELISAs and
 immunoblotting procedures, respectively. Results: Among the
 fractions mainly containing the single phenols hydroxytyrosol and
 tyrosol, the polyphenol acid elenolic acid, the lignans (+)-
 pinoresinol and 1-(+)-acetoxypinoresinol, and the secoiridoids
 deacetoxy oleuropein aglycone, ligstroside aglycone, and
 oleuropein aglycone, all the major EVOO polyphenols (i. e.
 secoiridoids and lignans) were found to induce strong tumoricidal
 effects within a micromolar range by selectively triggering high
 levels of apoptotic cell death in HER2-overexpressors. Small
 interfering RNA-induced depletion of HER2 protein and lapatinib-
 induced blockade of HER2 tyrosine kinase activity both
 significantly prevented EVOO polyphenols-induced cytotoxicity.
 EVOO polyphenols drastically depleted HER2 protein and reduced
 HER2 tyrosine autophosphorylation in a dose- and time-dependent
 manner. EVOO polyphenols-induced HER2 downregulation occurred
 regardless the molecular mechanism contributing to HER2
 overexpression (i. e. naturally by gene amplification and
 ectopically driven by a viral promoter). Pre-treatment with the
 proteasome inhibitor MG132 prevented EVOO polyphenols-induced HER2
 depletion. Conclusion: The ability of EVOO-derived polyphenols to

inhibit HER2 activity by promoting the proteasomal degradation of the HER2 protein itself, together with the fact that humans have safely been ingesting secoiridoids and lignans as long as they have been consuming olives and OO, support the notion that the stereochemistry of these phytochemicals might provide an excellent and safe platform for the design of new HER2-targeting agents.

J Hodge, AM; Bassett, JK; Shivappa, N; Hébert, JR; English, DR; Giles, G; Severi, G Hodge, A. M.; Bassett, J. K.; Shivappa, N.; Hebert, J. R.; English, D. R.; Giles, G. G.; Severi, G. Dietary inflammatory index, Mediterranean diet score, and lung cancer: a prospective study CANCER CAUSES & CONTROL English Article

Diet; Inflammation; Lung cancer; Prospective; Smoking; Epidemiology C-REACTIVE PROTEIN; COLORECTAL-CANCER; POOLED ANALYSIS; RISK; ASSOCIATION; MARKERS; METAANALYSIS; CAROTENOIDS; CONSUMPTION; ADHERENCE Purpose To investigate prospectively the associations of Dietary Inflammatory Index (DII) and Mediterranean Diet Score (MDS) with lung cancer. Methods We used data from men and women aged 40-69 years at recruitment in 1990-1994, who were participants in the Melbourne Collaborative Cohort Study (n = 35,303). A total of 403 incident lung cancer cases were identified over an average 18-year follow-up. Hazard ratios (HR) were estimated using Cox regression, adjusting for smoking status and other risk factors, with age as the time metric. Results An inverse correlation was observed between the DII and MDS ($\rho = -0.45$), consistent with a higher DII being pro-inflammatory and less 'healthy,' while a high MDS reflects a 'healthier' diet. The DII was positively associated with risk of lung cancer in current smokers [HRQ4 (vs) (Q1) = 1.70 (1.02, 2.82); P-trend = 0.008] (p interaction between DII quartiles and smoking status = 0.03). The MDS was inversely associated with lung cancer risk overall [HR7-9 (vs 0-3) = 0.64 (0.45, 0.90); P-trend = 0.005] and for current smokers (HR7-9 vs 0-3 = 0.38 (0.19, 0.75); P-trend = 0.005) (p interaction between MDS categories and smoking status = 0.31). Conclusions The MDS showed an inverse association with lung cancer risk, especially for current smokers. A high DII, indicating a more pro-inflammatory diet, was associated with risk of lung cancer only for current smokers. A healthy diet may reduce the risk of lung cancer, especially in smokers. Despite sharing part of the chemical structure with other ligands of G-quadruplexes (G4s), the interaction of Scriptaid with G4s has not been explored before. We synthesized Scriptaid and screened its cytotoxic activity in cellular models of colorectal cancer (CRC). We extensively evaluated its biological activity by cell cycle, immunofluorescence, qRT-PCR and Western blot experiments. To identify the G4 targets of Scriptaid, we conducted a panel of binding assays. Here, we show that Scriptaid induced cytotoxicity, cell cycle arrest and nucleolar stress in CRC cells. Moreover, Scriptaid impaired RNA polymerase I (Pol I) transcription, stabilized G4s and caused DNA damage. Finally, we disclose that these effects were attributable to the binding of Scriptaid to G4s in ribosomal DNA. In conclusion, our work reveals that a primary impact of Scriptaid on human cells is the interaction with G4s. [Sanchez-Martin, Victoria; Tello-

 Tissue-Specific Methylation Biosignatures for
 Monitoring Diseases: An In Silico Approach INTERNATIONAL JOURNAL
 OF MOLECULAR SCIENCES English Article
 methylation; machine learning; microarrays;
 model; liquid biopsy; diabetes; breast cancer; osteoarthritis
 CELL-FREE DNA; BREAST-CANCER; INSULIN-RESISTANCE; GENE;
 OSTEOARTHRITIS; MUTATIONS; MARKERS; GROWTH; KNEE; RISK Tissue-
 specific gene methylation events are key to the pathogenesis of
 several diseases and can be utilized for diagnosis and monitoring.
 Here, we established an in silico pipeline to analyze high-
 throughput methylome datasets to identify specific methylation
 fingerprints in three pathological entities of major burden, i.e.,
 breast cancer (BrCa), osteoarthritis (OA) and diabetes mellitus
 (DM). Differential methylation analysis was conducted to compare
 tissues/cells related to the pathology and different types of
 healthy tissues, revealing Differentially Methylated Genes (DMGs).
 Highly performing and low feature number biosignatures were built
 with automated machine learning, including: (1) a five-gene
 biosignature discriminating BrCa tissue from healthy tissues (AUC
 0.987 and precision 0.987), (2) three equivalent OA cartilage-
 specific biosignatures containing four genes each (AUC 0.978 and
 precision 0.986) and (3) a four-gene pancreatic beta-cell-specific
 biosignature (AUC 0.984 and precision 0.995). Next, the BrCa
 biosignature was validated using an independent ccfdNA dataset
 showing an AUC and precision of 1.000, verifying the
 biosignature's applicability in liquid biopsy. Functional and
 protein interaction prediction analysis revealed that most DMGs
 identified are involved in pathways known to be related to the
 studied diseases or pointed to new ones. Overall, our data-driven
 approach contributes to the maximum exploitation of high-
 throughput methylome readings, helping to establish specific
 disease profiles to be applied in clinical practice and to
 understand human pathology. [Karaglanı, Makrina; Panagopoulou,

Healthcare resource utilization and costs associated with anogenital warts in Morocco INFECTIOUS AGENTS AND CANCER English Article

Anogenital warts; Genital warts; Condyloma acuminatum; Papillomavirus infections; Epidemiology; North Africa; Health care utilization; Health care costs EXTENDED MIDDLE-EAST; HUMAN-PAPILLOMAVIRUS; NORTH-AFRICA; CERVICAL-CANCER; GENITAL WARTS; BURDEN; EPIDEMIOLOGY; IMPACTBackground Human papillomavirus (HPV), primarily genotypes 6 and 11, cause the majority of cases of anogenital warts (AGW). Although benign, AGW are associated with a substantial economic and psychosocial burden. Several vaccines have been developed to prevent HPV. The objective of this study was to describe the epidemiology and healthcare resource utilization of AGW in Morocco, as well as the associated costs of treatment from the public healthcare perspective. Methods This was a descriptive analysis of questionnaire data obtained via a Delphi panel. The panel consisted of 9 physicians practicing in public hospitals in Morocco (4 dermatologists and 5 obstetricians/gynecologists). The questionnaire collected data on physician and practice characteristics, diagnostic tests and procedures, treatments, and follow-up (including recurrence) of patients with AGW. Questionnaire items on which $\geq 70\%$ of respondents agreed were considered as having consensus. Costs

associated with diagnosis, treatment, and follow-up were calculated in Moroccan dirham (MAD) and converted to euros (euro) based on official national price lists for public hospitals and the HCRU estimates from the questionnaire. Results The physician-estimated prevalence of AGW in Morocco was 1.6%-2.6% in women and 2.0%-5.3% in men. A mean (median) of 6.4 (4) patients per month per physician sought medical attention for AGW. Simple observation was the most common diagnostic method for AGW in both men and women, and excision was the most prescribed therapy (75%), requiring a mean of 2 visits. Recurrence occurred in approximately 27% of patients. The cost per case of managing AGW, including recurrence, was estimated at 2182-2872 MAD (euro207-272) for women and 2170-2450 MAD (euro206-233) for men. The total annual cost of medical consultations for AGW in Morocco ranged from 3,271,877 MAD to 4,253,703 MAD (euro310,828-404,102). Conclusions Expert consensus indicates that AGW represent a significant burden to the Moroccan public healthcare system. These data can inform policy makers regarding this vaccine-preventable disease. Adherence to a Mediterranean diet and risk of gastric adenocarcinoma within the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort study

AMERICAN JOURNAL OF CLINICAL NUTRITION

English

Article

BREAST-CANCER;

LIFE-STYLE; PATTERN; MORTALITY; SURVIVAL; QUALITY; HEALTH; WOMEN; CONSUMPTION; POPULATION

Background: The Mediterranean dietary pattern is believed to protect against cancer, although evidence from cohort studies that have examined particular cancer sites is limited. Objective: We aimed to explore the association between adherence to a relative Mediterranean diet (rMED) and incident gastric adenocarcinoma (GC) within the European Prospective Investigation into Cancer and Nutrition study. Design: The study included 485,044 subjects (144,577 men) aged 35-70 y from 10 European countries. At recruitment, dietary and lifestyle information was collected. An 18-unit rMED score, incorporating 9 key components of the Mediterranean diet, was used to estimate rMED adherence. The association between rMED and GC with respect to anatomic location (cardia and noncardia) and histologic types (diffuse and intestinal) was investigated. A calibration study in a subsample was used to control for dietary measurement error. Results: After a mean follow-up of 8.9 y, 449 validated incident GC cases were identified and used in the analysis. After stratification by center and age and adjustment for recognized cancer risk factors, high compared with low rMED adherence was associated with a significant reduction in GC risk (hazard ratio: 0.67; 95% CI: 0.47, 0.94). A 1-unit increase in the rMED score was associated with a decreased risk of GC of 5% (95% CI: 0.91, 0.99). There was no evidence of heterogeneity between different anatomic locations or histologic types. The calibrated results showed similar trends (overall hazard ratio for GC: 0.93; 95% CI: 0.89, 0.99). Conclusion: Greater adherence to an rMED is associated with a significant reduction in the risk of incident GC. Am J Clin Nutr 2010;91:381-90. Assessment of MRI to estimate metastatic dissemination risk and prometastatic effects of chemotherapy NPJ BREAST CANCER English
 Article CIRCULATING

TUMOR-CELLS; TIME IMAGING REVEALS; BREAST-CANCER; TIE2-EXPRESSING MONOCYTES; MULTIPHOTON MICROSCOPY; MACROPHAGE REGULATION; MAMMARY-TUMORS; BLOOD-VESSELS; MOUSE MODEL; EXPRESSION Metastatic dissemination in breast cancer is regulated by specialized intravasation sites called "tumor microenvironment of metastasis" (TMEM) doorways, composed of a tumor cell expressing the actin-regulatory protein Mena, a perivascular macrophage, and an endothelial cell, all in stable physical contact. High TMEM doorway number is associated with an increased risk of distant metastasis in human breast cancer and mouse models of breast carcinoma. Here, we developed a novel magnetic resonance imaging (MRI) methodology, called TMEM Activity-MRI, to detect TMEM-associated vascular openings that serve as the portal of entry for cancer cell intravasation and metastatic dissemination. We demonstrate that TMEM Activity-MRI correlates with primary tumor TMEM doorway counts in both breast cancer patients and mouse models, including MMTV-PyMT and patient-derived xenograft models. In addition, TMEM Activity-MRI is reduced in mouse models upon treatment with rebastinib, a specific and potent TMEM doorway inhibitor. TMEM Activity-MRI is an assay that specifically

J Fokkema, T; de Haas, H Fokkema, Tineke; de Haas, Hein Pre- and Post-Migration Determinants of Socio-Cultural Integration of African Immigrants in Italy and Spain INTERNATIONAL MIGRATION English Article 2ND-GENERATION; UNEMPLOYMENT; EUROPE; TRANSNATIONALISM; PARTICIPATION; ASSIMILATION; NETHERLANDS; DESTINATION; COMMUNITY; MOROCCAN

Using a unique dataset (N=2,014), we examine the pre- and post-migration determinants of socio-cultural integration among first-generation immigrant groups in southern Europe: Moroccan and Senegalese migrants in Spain, and Egyptian and Ghanaian migrants

in Italy. The results of the pooled and immigrant-group specific regression analyses partly highlight the dominance of pre-migration factors. Immigrants who were well-educated and well-informed prior to migrating and who migrate at a young age, achieve higher levels of socio-cultural integration. Going against some hypotheses found in the literature, female gender and North African origin have a positive effect on socio-cultural integration as opposed to male gender and sub-Saharan origin. With regard to post-migration factors, occupational status is the main economic determinant of socio-cultural integration. Interestingly, being employed as such has no significant effect on socio-cultural integration. This suggests that labour market segmentation and discrimination negatively impact upon socio-cultural integration. The results also suggest that policies allowing immigrants to benefit from the human capital they carry across borders and achieve upward socio-economic mobility are likely to enhance their socio-cultural integration. Fallahi, Jafar Identifying a Novel Pathogenic

Mutation in Exon 3 of ARID1A Gene in Colon Cancer MIDDLE EAST

JOURNAL OF CANCER

English Article

ARID1A; Colon cancer; Novel mutation

EXPRESSION ARID1A, a bona fide tumor suppressor, is the third most mutated gene in human colorectal cancer. In this paper, we reported the identification of a novel mutation in one of 20 primary human colorectal cancer tumors. Sanger sequencing of the exon 3 of the ARID1A gene revealed a novel heterozygous non-sense mutation of the c.1653C>G. This resulted in the premature termination of the 2285 amino acid protein at the 551st codon. Mutation Taster predicted this novel mutation to be pathogenic. Immunohistochemical analysis revealed the loss of ARID1A protein expression in cancerous tissues harboring ARID1A mutation. As far as we know, this is the first report on the mutation of ARID1A gene in an Iranian patient. This mutation can expand the spectrum of ARID1A gene pathogenic mutations among colorectal cancer patients. [Erfani, Mehran; Mokarram, Pooneh] Shiraz Univ Med

Immigrant health care workers from developing countries in
the US: antecedents, consequences and institutional responses
EQUALITY DIVERSITY AND INCLUSION English
Article Immigrants;

Developing countries; Racial discrimination; Health services;
Diversity management; International medical graduates

AFFIRMATIVE-ACTION; LABOR MIGRATION; BRAIN-DRAIN; DIVERSITY;
ACCULTURATION; INCLUSION; PATTERNS; MIGRANTS; POLICIES; DOCTORS

Purpose The aim of this paper is to present a conceptual model on foreign-born health care workers from developing countries working in the US. The model covers their motivations for migration, the consequences in terms of the inequality and exclusion they may experience and the role of institutional responses at micro-, macro- and meso-level of intervention. Design/methodology/approach The paper is based on: (1) in-depth review of key literature studies on the foundation theories of international migration including sociology, economics, anthropology, psychology and human resource management, (2) analysis of theoretical approaches to medical migration across disciplines, (3) analysis of the international and national documentary sources of micro-, macro- and meso-level policies on migration and (4) analysis of evidence on best practices, solutions and aspirational changes across different levels of institutions. Findings (1) Migration of international medical graduates (IMGs) from developing countries to the US can be explained from a micro-, macro- and meso-level of analysis. (2) IMGs who identify as racial/ethnic minorities may experience unfair discrimination differently than their US-born counterparts. (3) Although political/legislative remedies have had some successes, proactive initiatives will be needed alongside

enforcement strategies to achieve equity and inclusion. (4) While diversity management initiatives abound in organizations, those designed for the benefit of IMGs from developing countries are rare. (5) Professional identity groups and some nonprofits may challenge structural inequities, but these have not yet achieved economies of scale. Research limitations/implications Although it is well-documented in the US health care literature how ethnic/racial minorities are unfairly disadvantaged in work and career, the studies are rarely disaggregated according to sub-groups (e.g. non-White IMGs and US-born MGs). The implication is that Black IMG immigrants have been overlooked by the predominant narratives of native-born, Black experiences. In placing the realities of native-born Blacks on the entire Black population in America, data have ignored and undermined the diverse histories, identities and experiences of this heterogeneous group. Practical implications An awareness of the challenges IMGs from developing countries face have implications for managerial decisions regarding recruitment and selection. Besides their medical qualifications, IMGs from developing countries offer employers additional qualities that are critical to success in health care delivery. Considering organizations traditionally favor White immigrants from Northern and Southern Europe, IMGs from developed countries migrate to the US under relatively easier circumstances. It is important to balance the scale in the decision-making process by including an evaluation of migration antecedents in comprehensive selection criteria. Social implications The unfair discrimination faced by IMGs who identify as racial/ethnic minority are multilayered and will affect them in ways that are different compared to their US-born counterparts. In effect, researchers need to make this distinction in research on racial discrimination. Since IMGs are not all uniformly impacted by unfair discrimination, organization-wide audits should be in tune with issues that are of concerns to IMGs who identify as racial/ethnic minorities. Likewise, diversity management strategies should be more inclusive and should not ignore the intersectionality of race/ethnicity, nationality, country of qualification and gender. Originality/value Immigrant health care workers from developing countries are integral to the health care industry in the United States. They make up a significant proportion of all workers in the health care industry in the US. Although the literature is replete with studies on immigrant health care workers as a whole, research has rarely focused on immigrant health care workers from developing countries. The paper makes a valuable contribution in drawing attention to this underappreciated group, given their critical role in the ongoing pandemic and the need for the US health industry to retain their services to remain viable in the future. Richard; Aggarwal, Ajay Economic impact of
avoidable cancer deaths caused by diagnostic delay during the
COVID-19 pandemic: A national population-based modelling study in
England, UKEUROPEAN JOURNAL OF CANCER English
Article COVID-19; Cancer;
Avoidable deaths; Quality-adjusted life years; Economics;
Productivity; Diagnostic delay Introduction: Delays in
cancer diagnosis arose from the commencement of non pharmaceutical
interventions (NPI) introduced in the UK in March 2020 in response
to the COVID-19 pandemic. Our earlier work predicted this will
lead to approximately 3620 avoidable deaths for four major tumour
types (breast, bowel, lung, and oesophageal cancer) in the next 5
years. Here, using national population-based modelling, we
estimate the health and economic losses resulting from these
avoidable cancer deaths. We also compare these with the impact of
an equivalent number of COVID-19 deaths to understand the welfare
consequences of the different health conditions. Methods: We
estimate health losses using quality-adjusted life years (QALYs)
and lost economic productivity using the human capital (HC)
approach. The analysis uses linked English National Health Service
(NHS) cancer registration and hospital administrative datasets for
patients aged 15-84 years, diagnosed with breast, colorectal, and
oesophageal cancer between 1st Jan to 31st Dec 2010, with follow-

up data until 31st Dec 2014, and diagnosed with lung cancer between 1st Jan to 31st Dec 31 2012, with follow-up data until 31st Dec 2015. Productivity losses are based on the estimation of excess additional deaths due to cancer at 1, 3 and 5 years for the four cancer types, which were derived from a previous analysis using this dataset. A total of 500 random samples drawn from the total number of COVID-19 deaths reported by the Office for National Statistics, stratified by gender, were used to estimate productivity losses for an equivalent number of deaths ($n = 3620$) due to SARS-CoV-2 infection. Results: We collected data for 32,583 patients with breast cancer, 24,975 with colorectal cancer, 6744 with oesophageal cancer, and 29,305 with lung cancer. We estimate that across the four site-specific cancers combined in England alone, additional excess cancer deaths would amount to a loss of 32,700 QALYs (95% CI 31,300-34,100) and productivity losses of 103.8million pound GBP (73.2-132.2) in the next five years. For breast cancer, we estimate a loss of 4100 QALYs (3900-4400) and productivity losses of 23.2 pound m (18.2-28.6); for colorectal cancer, 15,000 QALYs (14,100-16,000) lost and productivity losses of 35.7 pound m (22.4-48.7); for lung cancer 10,900 QALYs (9,900-11,700) lost and productivity losses of 38.3 pound m (14.0-59.9) for lung cancer; and for oesophageal cancer, 2700 QALYs (2300-3,100) lost and productivity losses of 6.6 pound m (-6 to-17.6). In comparison, the equivalent number of COVID-19 deaths caused approximately 21,450 QALYs lost, as well as productivity losses amounting to 76.4 pound m (73.5-79.2). Conclusion: Premature cancer deaths resulting from diagnostic delays during the first wave of the COVID-19 pandemic in the UK will result in significant economic losses. On a per-capita basis, this impact is, in fact, greater than that of deaths directly attributable to COVID-19. These results emphasise the importance of robust evaluation of the trade-offs of the wider health, welfare and economic effects of NPI to support both resource allocation and the prioritisation of time-critical health services directly impacted in a pandemic, such as cancer care. 2021 The Author(s). chromatography; mass spectrometry; Mediterranean Sea; tolerable
daily intake (TDI) PERSISTENT ORGANIC POLLUTANTS;
POLYUNSATURATED FATTY-ACIDS; POLYCHLORINATED-BIPHENYLS;
ORGANOCHLORINE PESTICIDES; BREAST-CANCER; EXPOSURE;
POLYCHLOROBIPHENYLS; PRODUCTS; SALMON; BIRTH A sampling campaign
from 21 sites in Italy was conducted: 15 species from fishery and
three species from aquaculture, for a total of 40 determinations,
were considered. A careful sample preparation preceded the
instrumental analysis that was carried out by means of GC-ECD and
GC-MS. Good laboratory practice was achieved by the participation
in proficiency tests, by the use of certified reference materials
and by applying other directives recommended by international
organisations. Concentrations measured in this work were compared
with a TDI proposed by some international bodies: for a person
weighing 70kg one-third of the samples from fishery, when
consumed, lead to exceed this TDI if the average fish daily
consumption per capita is considered. Based on the data obtained
here some hypotheses on environmental spreading and influence of
PCBs on human health are made. Some suggestions about the
preparation of fish for consumption are also given. [Masci,

Engin Human estrogen receptor alpha (ER α) targeted
cyclic peptides inhibit cell growth and induce apoptosis in MCF-7
cells TURKISH JOURNAL OF BIOCHEMISTRY-TURK BIYOKIMYA DERGISI
English Article

apoptosis; breast cancer; coactivator binding inhibitors; helix-stabilized cyclic peptides; human estrogen receptor alpha

HUMAN BREAST-CANCER; STAPLED PEPTIDES; SELECTIVE INHIBITORS; HELICAL PEPTIDES; BINDING; RESISTANCE; ASSAY Objectives Human estrogen receptor alpha (ER alpha) is considered an important target, especially in the treatment of breast cancer, as it has a vital role in cancer development. ER alpha-targeted therapies generally target the ligand binding domain (LBD) of ER alpha. However, over time, cells develop resistance to this mechanism alternative approaches to inhibit ER alpha activity target ER alpha-DNA or ER alpha-cofactor interactions. Inhibitors of ER alpha-cofactor interactions are designed by targeting the hydrophobic hollow region of the receptor box LXXLL motif. Methods In this context, helix-stabilized cyclic peptides (SPs) designed with in silico approaches were obtained by solid phase peptide synthesis. The effects of SPs on MCF-7 cells were examined with MTT and ATP, and qPCR and flow cytometry were used for further analysis. Results Our results demonstrated that the SPs were effective only in MCF-7 cells expressing ER alpha. In addition, cyclic peptide combinations (SPCs) showed anti-proliferative and toxic effects on MCF-7 cells. The impact of SPCs with the highest inhibitory effect in MCF-7 cells on ER alpha-related genes and markers of apoptosis was revealed. Moreover, the flow cytometry analysis result used to examine apoptotic cells proved the apoptosis of SPCs in MCF-7 cells. Conclusions These findings suggest that our novel SPs, which inhibit coactivator interactions of ER alpha, induce apoptosis of MCF-7 cells. Thus, considering this strong effect of SPs in the inhibition of receptors, it is pointed out that they can be further developed as an alternative to current clinical treatments or as an auxiliary approach in the generating of new targeted peptide-based therapies. Estefania Adherence to the Mediterranean Diet and
Obesity-Linked Cancer Risk in EPIC JAMA NETWORK OPEN
English Article

COLORECTAL-CANCER; WEIGHT CHANGE; VALIDITY; PATTERNS;
INFLAMMATION; REPRODUCIBILITY; QUESTIONNAIRE; PARTICIPANTS;
CALIBRATION; VALIDATION Importance Adherence to the
Mediterranean Diet (MedDiet) has been associated with a lower
incidence of cancer and reduced weight gain. These associations
suggest a potential role for the MedDiet in lowering the risk of
obesity-related cancers (ORCs). Obesity is a known risk factor for
various cancers and shows an inverse association with MedDiet
adherence. Objective To examine the association between adherence
to the MedDiet and the risk of ORCs, considering the possible
mediating role of adiposity. Design, Setting, and Participants
This prospective cohort study analyzed data from the European
Prospective Investigation Into Cancer and Nutrition (EPIC) study,
which enrolled participants aged 35 to 70 years from 1992 to 2000
across 23 centers in 10 countries. The data analysis was conducted
from March 1 to May 31, 2023. Exposures Dietary intake before
baseline was evaluated using country-specific, validated
questionnaires administered at recruitment. Adherence to the
MedDiet was scored on a 9-point scale and categorized as low (0-3
points), medium (4-6 points), or high (7-9 points). Main Outcomes
and Measures The primary outcome was the incidence of ORCs,
classified according to the 2015 International Agency for Research
on Cancer criteria. Multivariable Cox proportional hazards
regression models were used to assess the association between
MedDiet adherence and ORC incidence. Mediation analyses were
conducted to evaluate the role of waist to hip ratio and body mass
index in this association. Results A total of 450 111 participants
were included in the study (mean [SD] age, 51.1 [9.8] years; 70.8%
women) and followed up during a median (IQR) time of 14.9 (4.1)
years. Among participants, 4.9% experienced an ORC (rates, 0.053,
0.049, and 0.043 per person-year in the low, medium, and high

MedDiet adherence groups, respectively). Participants with high adherence to the MedDiet (7-9 points) had a lower risk of ORC compared with those with low adherence (0-3 points) (hazard ratio [HR], 0.94; 95% CI, 0.90-0.98). A similar inverse association was observed for participants with medium adherence (4-6 points vs 0-3 points). However, mediation analyses did not show associations of waist to hip ratio or body mass index between MedDiet adherence and ORC risk. Conclusions and Relevance These findings indicate that higher adherence to the MedDiet is associated with a modest reduction in the risk of ORCs, independent of adiposity measures. Further research is needed to clarify the mechanisms by which the MedDiet may contribute to cancer prevention. NCD Risk Factor

Collaboration Worldwide trends in blood pressure from 1975 to 2015: a pooled analysis of 1479 population-based measurement studies with 19.1 million participants LANCET

English Article

CARDIOVASCULAR RISK-FACTORS; HEALTH EXAMINATION SURVEYS; HYPERTENSION PREVALENCE; UNITED-STATES; SYSTEMATIC ANALYSIS; GENDER-DIFFERENCES; SECULAR TRENDS; GLOBAL BURDEN; SODIUM-INTAKE; LOW-INCOME Background Raised blood pressure is an important risk factor for cardiovascular diseases and chronic kidney disease. We estimated worldwide trends in mean systolic and mean diastolic blood pressure, and the prevalence of, and number of people with, raised blood pressure, defined as systolic blood pressure of 140 mm Hg or higher or diastolic blood pressure of 90 mm Hg or higher. Methods For this analysis, we pooled national, subnational, or community population-based studies that had measured blood pressure in adults aged 18 years and older. We used a Bayesian hierarchical model to estimate trends from 1975 to 2015 in mean systolic and mean diastolic blood pressure, and the prevalence of raised blood pressure for 200 countries. We calculated the contributions of changes in prevalence versus population growth and ageing to the increase in the number of adults with raised blood pressure. Findings We pooled 1479 studies that had measured the blood pressures of 19.1 million adults. Global age-standardised mean systolic blood pressure in 2015 was 127.0 mm Hg (95% credible interval 125.7-128.3) in men and 122.3 mm Hg (121.0-123.6) in women; age-standardised mean diastolic blood pressure was 78.7 mm Hg (77.9-79.5) for men and 76.7 mm Hg (75.9-77.6) for women. Global age-standardised prevalence of raised blood pressure was 24.1% (21.4-27.1) in men and 20.1% (17.8-22.5) in women in 2015. Mean systolic and mean diastolic blood pressure decreased substantially from 1975 to 2015 in high-income western and Asia Pacific countries, moving these countries from having some of the highest worldwide blood pressure in 1975 to the lowest in 2015. Mean blood pressure also decreased in women in central and eastern Europe, Latin America and the Caribbean, and, more recently, central Asia, Middle East, and north Africa, but the estimated trends in these super-regions had larger uncertainty than in high-income super-regions. By contrast, mean blood pressure might have increased in east and southeast Asia, south Asia, Oceania, and sub-Saharan Africa. In 2015, central and eastern Europe, sub-Saharan Africa, and south Asia had the highest blood pressure levels. Prevalence of raised blood pressure decreased in high-income and some middle-income countries; it remained unchanged elsewhere. The number of adults with raised blood pressure increased from 594 million in 1975 to 1.13 billion in 2015, with the increase largely in low-income and middle-income countries. The global increase in the number of adults with raised blood pressure is a net effect of increase due to population growth and ageing, and decrease due to declining age-specific prevalence. Interpretation During the past four decades, the highest worldwide blood pressure levels have shifted from high-income countries to low-income countries in south Asia and sub-Saharan Africa due to opposite trends, while blood pressure has been persistently high in central and eastern Europe. All-trans-retinoic acid; poly(D,L-lactide-co-glycolide); microparticles; polymeric drug carrier;
drug delivery CELL-PROLIFERATION; DELIVERY; DRUG;
NANOPARTICLES; MICROSPHERES; POLY(DL-LACTIDE-CO-GLYCOLIDE);
MICROPARTICLES; EMULSION; SYSTEMS Polymeric biomaterials are being
investigated for the last several years because of their
controllable properties. In this study, it was aimed to prepare
and evaluate the atRA carrying system using Poly(lactide-co-glycolide) (PLGA). Microparticles were characterized in terms of
morphology and encapsulation efficiency. Release studies were
performed for the evaluation of drug release rates. Cytotoxicity
tests were implemented on MCF-7 Human breast cancer cell line for
the investigation of drug and polymer toxicity. The microparticles
were found smooth and spherical in shape. However, as the loaded
drug amount increased, the sizes of microparticles also increased
and the size distribution became less uniform. The sizes of atRA-
loaded microparticles ranged between 1-10 μ m. The encapsulation
efficiency of atRetinoic acid (all-trans-Retinoic acid) was

achieved approximately %90. Approximately, 45% of atRA was released from atRA-loaded microparticles by the end of 4-5 days. Cell growth inhibition was observed after 4 days of incubation of cells with PLGA microparticles. [Daskin, Demet; Gunduz, Ufuk] Middle E Tech Univ, Dept Biol Sci, TR-06531 Ankara, Turkey

contraceptive careseeking: the experience of Eritrean asylum-seeking women in Israel ETHNICITY & HEALTH

English Article Family planning; contraception; Eritrean women; migration; Israel; Middle East QUALITATIVE RESEARCH; HEALTH-CARE; MIGRATION; PROTECTION; MIGRANTS; ACCESS; RIGHTS Objectives: In recent years, there has been a mass migration of Eritreans (many seeking political asylum) into Israel after precarious irregular movement across international borders. This study qualitatively explores the structural barriers to family planning (i.e. contraceptive services) for Eritrean women in Israel that are rooted in their temporary legal status and the patchwork of family planning services. Design/Methods: From December 2012 to September 2013, we interviewed 25 key informants (NGO workers, researchers, Eritrean community activists, International NGO representatives and Ministry of Health officials) and 12 Eritrean asylum seekers. We also conducted 8 focus groups with Eritrean asylum seekers. Data were analyzed using both inductive and deductive coding. Results: We identified 7 main barriers to accessing family planning services: (1) distance to health facilities; (2) limited healthcare resources; (3) fragmentation of the healthcare system; (4) cost of contraceptive services; (5) low standard of care in private clinics; (6) discrimination; and (7) language barriers. Conclusion: The political, economic and social marginalization of Eritrean asylum-seeking women in Israel creates structural barriers to family planning services. Their marginalization complicates providers' efforts (NGO and governmental) to provide them with comprehensive healthcare, and hinders their ability to control their sexual and reproductive health. Failure to act on this evidence may perpetuate the pattern of unwanted pregnancies and social and economic disparities in this population.

Adequacy of Critical Nutrients Affecting the Quality of the Spanish Diet in the ANIBES Study NUTRIENTS

English Article adequacy of intake; diet quality; diet quality indexes; dietary recommended intakes; nutrients MEDITERRANEAN DIET; GOLDBERG CUTOFF; ADHERENCE; MORTALITY; SURVIVAL; HEALTH; TRENDS; INCOME; SCORE; GREEK Diet is one of the key modifiable behaviors that can help to control and prevent non-communicable chronic diseases. Therefore, it is important to evaluate the overall diet composition of the population through non-invasive and independent indexes or scores as diet quality indexes (DQIs). The primary aim of the present work was to estimate the adequacy of the intake of critical nutrients in the Spanish "Anthropometry, Intake, and Energy Balance Study" (ANIBES) (n = 2285; 9-75 years), considering, as a reference, the European Food Scientific Authority (EFSA) values for nutrients for the European Union. We also assessed the quality of the diet for adults and older adults using four internationally accepted DQIs, namely the Healthy Diet Indicator (HDI), the Mediterranean Diet Score (MDS), the Mediterranean Diet Score-modified (MDS-mod), and the Mediterranean-Diet Quality Index (MED-

DQI), as well as the ANIBES-DQI, stratified by education and income. The ANIBES-DQI was based on compliance with EFSA and Food and Agriculture Organization recommendations for a selected group of nutrients (i.e., total fat, saturated fatty acids (SFAs), simple sugars, fiber, calcium, vitamin C, and vitamin A), with a total range of 0-7. Misreporting was assessed according to the EFSA protocol, which allowed us to assess the DQIs for both the general population and plausible reporters. The majority of the Spanish population had high intakes of SFAs and sugars and low intakes of fiber, folate, and vitamins A and C. In addition, about half of the population had low DQI scores and exhibited low adherence to the Mediterranean diet pattern. Overall, older adults (>65-75 years) showed better DQIs than adults (18-64 years), without major differences between men and women. Moreover, primary education and low income were associated with low MDS and ANIBES-DQI scores. For the ANIBES-DQI, the percentage of the population with low scores was higher in the whole population (69.5%) compared with the plausible energy reporters (49.0%), whereas for medium and high scores the percentages were higher in plausible reporters (41.2% vs. 26.2% and 9.8% vs. 4.3%, respectively). In conclusion, the present study adds support to marked changes in the Mediterranean pattern in Spain, and low education and income levels seem to be associated with a low-quality diet. Additionally, the misreported evaluation in the ANIBES population suggests that this analysis should be routinely included in nutrition surveys to give more precise and accurate data related to nutrient intake and diet quality.

The potential application of gold-apoferritin nanocages conjugated with 2-amino-2-deoxy-glucose for imaging of breast cancer cells JOURNAL OF BIOLOGICAL INORGANIC CHEMISTRY English Article

Apoferitin; In vitro imaging; Gold nanoparticles; X-ray computed tomography GLUCOSE-METABOLISM; PROTEIN CAGES; NANOPARTICLES; FERRITIN; TUMORS; SIZE; MRI; PLATFORMS; COMPLEX; SILVER

Development of biocompatible and multifunctional nanoprobes for tumor targeting, imaging, and therapy still remains a great challenge. Herein, gold nanoparticles (AuNPs) were synthesized in the cavity of horse spleen apoferritin protein (HoSAF) and protein surface was labeled with 2-amino-2-deoxy-glucose (2DG) as a cell surface glucose transport protein specific targeting probe to study the feasibility of its usage as a computer tomography (CT) contrast agent with tumor targeting capability through in vitro experiments. 2DG conjugated and gold-loaded apoferritin (Au-HoSAF-2DG) nanoparticles (NPs) showed selective targeting for human breast adenocarcinoma (MCF-7) cells when compared to normal breast (MCF-10A) cells. This AuNP-based imaging agent was found to be non-cytotoxic in a given concentration range with an apoptotic effect upon longer exposure times towards MCF-7 cells, while MCF-10A cells were affected less. This selective cell death would also be useful for further cancer treatments with the ability of X-ray attenuation in in vitro X-ray and computed tomography (CT) imaging. [GRAPHICS] . English Article

NANOMEDICINE; HYDROGELS; DELIVERY; THERAPEUTICS; CELLS
Here, we reported the production of hyaluronic acid/polyaspartamide-based double-network nanogels for the potential treatment of colorectal carcinoma. Graphene oxide, thanks to the huge aromatic surface area, allows to easily load high amount of irinotecan (33.0% w/w) and confers to the system hyperthermic properties when irradiated with a near infrared (NIR) laser beam. We demonstrate that the release of antitumor drug is influenced both by the pH of the external medium and the NIR irradiation process. In vitro biological studies, conducted on human colon cancer cells (HCT 116), revealed that nanogels are uptaken by the cancer cells and, in HA-EDA the presence of the antitumor drug, can produce a synergistic hyperthermic/cytotoxic effect. Finally, 3D experiments demonstrate that it is possible to conduct thermal ablation of solid tumors after the intratumoral administration of nanogels.  Virus Vaccination in a Private Women Health Clinic in Lebanon
 OBSTETRICS AND GYNECOLOGY INTERNATIONAL English
 Article EXTENDED
 MIDDLE-EAST; HPV VACCINE; ACCEPTABILITY; INFECTIONS; PREVENTION;
 SEXUALITY; IMPACT Objectives. The study aims to report on the
 feasibility and associated adverse events of HPV-Vaccination
 (HPVV) in a private clinic setting in Lebanon and, when available,
 the results of subsequent cervical cancer screening. Methods.
 Opportunistic HPV vaccination is offered at the Women's Health
 Center of the AUBMC. We retrospectively reviewed the patients'
 demographic data, the incidence of adverse events, and their
 cytological screening. Results. A cohort of healthy women (n =
 1013) aged 26.2 years (12-54 years) were opportunistically
 vaccinated with one of two HPV vaccines; 845 (83.4%) received the
 quadrivalent vaccine (Q4V), and 151 (14.1%) received the bivalent
 vaccine (B2V). The majority (75.8%) received three doses while 16%
 received two doses. Out of these women, 26.3% (267) became
 sexually active postvaccination (NS2), whereas 17% (174) were
 sexually active prior to vaccination (SA) and the rest 57% (572)
 reported no sexual activity (NS1). Among the SA group, 26%
 (46/147) presented with abnormal cytology at time of vaccination.
 As for the NS2 women, 5% (14/267) had subsequently abnormal
 screening within 37 (12-103) months following vaccination.
 Conclusions. In this observational study, we report the successful
 introduction of HPVV with negligible adverse events. The incidence
 of abnormal cervical cytology was low among our patients.

 Designing of CD8⁺ and CD8⁺-
overlapped CD4⁺ epitope vaccine by targeting late and
early proteins of human papillomavirus BIOLOGICS-TARGETS &
THERAPY English Article

 human leukocyte antigen; killer cells; overlapped
epitopes; time course simulation T-CELL EPITOPES; MHC CLASS-I;
INVASIVE CERVICAL-CANCER; HPV INFECTION; TYPE-16 E6; WOMEN;
PEPTIDE; PREDICTION; IDENTIFICATION; EXPRESSION Background and
aim: Human papillomavirus (HPV) is an oncogenic agent that causes
over 90% of cases of cervical cancer in the world. Currently
available prophylactic vaccines are type specific and have less
therapeutic efficiency. Therefore, we aimed to predict the
potential species-specific and therapeutic epitopes from the
protein sequences of HPV45 by using different immunoinformatics
tools. Methods: Initially, we determined the antigenic potential
of late (L1 and L2) and early (E1, E2, E4, E5, E6, and E7)
proteins. Then, major histocompatibility complex class I-
restricted CD8(+) T-cell epitopes were selected based on their
immunogenicity. In addition, epitope conservancy, population
coverage (PC), and target receptor-binding affinity of the
immunogenic epitopes were determined. Moreover, we predicted the
possible CD8(+), nested interferon gamma (IFN-gamma)-producing
CD4(+), and linear B-cell epitopes. Further, antigenicity,
allergenicity, immunogenicity, and system biology-based virtual
pathway associated with cervical cancer were predicted to confirm
the therapeutic efficiency of overlapped epitopes. Results:
Twenty-seven immunogenic epitopes were found to exhibit cross-
protection ($\geq 55\%$) against the 15 high-risk HPV strains (16, 18,
31, 33, 35, 39, 51, 52, 56, 58, 59, 68, 69, 73, and 82). The
highest PC was observed in Europe (96.30%), North America
(93.98%), West Indies (90.34%), North Africa (90.14%), and East
Asia (89.47%). Binding affinities of 79 docked complexes observed
as global energy ranged from -10.80 to -86.71 kcal/mol. In
addition, CD8(+) epitope-overlapped segments in CD4(+) and B-cell
epitopes demonstrated that immunogenicity and IFN-gamma-producing
efficiency ranged from 0.0483 to 0.5941 and 0.046 to 18,
respectively. Further, time core simulation revealed the
overlapped epitopes involved in pRb, p53, COX-2, NF-X1, and HPV45
infection signaling pathways. Conclusion: Even though the results
of this study need to be confirmed by further experimental peptide
sensitization studies, the findings on immunogenic and IFN-gamma-
producing CD8(+) and overlapped epitopes provide new insights into
HPV vaccine development. [Kaliamurthi, Satyavani; Selvaraj,

Regulation of stressed-induced cell death by the Bcl-2
family of apoptotic proteins MOLECULAR MEMBRANE BIOLOGY
English Article

Apoptosis; Bcl-2 family proteins; caspase; cytochrome c;
cancer COLORECTAL-CANCER CELLS; MITOCHONDRIAL-MEMBRANE; BH3-
ONLY PROTEINS; LEUKEMIA-CELLS; CYTOCHROME-C; T-CELLS; B-CELLS;
PUMA; NOXA; P53 Apoptosis is often deregulated in a number of
human diseases. Heat-induced apoptosis is a model system for
studying the consequences of protein misfolding and is mediated by
the Bcl-2 family of proteins. This family consists of both pro-
apoptotic and anti-apoptotic members that control mitochondrial
integrity. The BH3-only pro-apoptotic members are strong inducers
of apoptotic cell death. Protein damaging stress can activate a
process of cellular destruction known as apoptosis. The pro-
apoptotic BH3-only proteins and transcription factors activate
this death pathway by inhibiting the anti-apoptotic Bcl-2 family
proteins eliminating cancer cells in a short period of time.

Genetic diversity of human papillomavirus (HPV) as
 specified by the detection method, gender, and year of sampling: a
 retrospective cross-sectional study ARCHIVES OF GYNECOLOGY AND
 OBSTETRICS English Article

Cervical cancer; Genetic diversity; Genotypes; Human
 papillomavirus EXTENDED MIDDLE-EAST; CERVICAL-CANCER; INFECTION;
 PREVALENCE; WOMEN; RISK; CLASSIFICATION; PERFORMANCE; GENOTYPES;
 SMEAR Purpose This study assesses HPV prevalence and genotype
 distribution in Lebanon, and identifies differentials in HPV
 infection, infection with multiple genotypes, and with high-risk
 genotypes, by sex, age, and year of data collection. Methods Study
 participants comprised 1042 female and 160 male participants
 between 2006 and 2018. HPV genotyping was done by PCR and
 hybridization (2006-2013) or real-time PCR (2013 onwards).
 Diversity of HPV genotypes across gender, age groups, and years of
 data collection was tested by applying Shannon Diversity
 Index. Results The overall HPV prevalence was 44.8% among study
 participants, and threefold higher in women than men. Single HPV
 infection was seen in two-third of HPV-positive participants.
 Women were less likely to be infected with multiple HPV strains,
 but more likely to be infected with high-risk or mixed-risk HPV
 genotypes. HPV-16 (11.0%, 9.8%) and HPV-53 (8.5%, 4.9%) were the
 most prevalent high-risk HPV genotypes in women and men,
 respectively, while HPV-18 prevalence was 4.9% in men and 3.1% in
 women, while HPV-59 prevalence was 6.6% in men and 2.1% in women.
 Samples collected post-2011 from women showed twice higher odds of
 HPV infection than those collected earlier and were threefold more
 likely to be infected with multiple HPV strains, and twice more
 likely to be infected with high-risk genotypes compared to those
 tested earlier. Women scored higher on Shannon index indicating
 high diversity in HPV types and frequency, with trend of increased
 diversity over time. While the odds of HPV infection remained
 associated with sex and temporal trend in multivariable analysis,
 odds of having high-risk genotypes was mainly associated with
 infection with multiple HPV strains. Conclusion Our study showed
 high diversity in HPV genotypes and an increasing trend of
 infection with multiple and high-risk genotypes in recent years.
 Findings underscore the need for effective screening/surveillance
 and HPV vaccination programs. [Finan, Ramzi R.] St Joseph

Mitochondrial Fraction of Circulating Cell-Free DNA as an Indicator of Human Pathology INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES English Article

mitochondrial; ccfDNA; prediabetes; breast cancer; diabetes; osteoarthritis; machine learning BIOMARKER

Circulating cell-free DNA (ccfDNA) of mitochondrial origin (ccf-mtDNA) consists of a minor fraction of total ccfDNA in blood or in other biological fluids. Aberrant levels of ccf-mtDNA have been observed in many pathologies. Here, we introduce a simple and effective standardized Taqman probe-based dual-qPCR assay for the simultaneous detection and relative quantification of nuclear and mitochondrial fragments of ccfDNA. Three pathologies of major burden, one malignancy (Breast Cancer, BrCa), one inflammatory (Osteoarthritis, OA) and one metabolic (Type 2 Diabetes, T2D), were studied. Higher levels of ccf-mtDNA were detected both in BrCa and T2D in relation to health, but not in OA. In BrCa, hormonal receptor status was associated with ccf-mtDNA levels. Machine learning analysis of ccf-mtDNA datasets was used to build biosignatures of clinical relevance. (A) a three-feature biosignature discriminating between health and BrCa (AUC: 0.887) and a five-feature biosignature for predicting the overall survival of BrCa patients (Concordance Index: 0.756). (B) a five-feature biosignature stratifying among T2D, prediabetes and health (AUC: 0.772); a five-feature biosignature discriminating between T2D and health (AUC: 0.797); and a four-feature biosignature identifying prediabetes from health (AUC: 0.795). (C) a

biosignature including total plasma ccfDNA with very high performance in discriminating OA from health (AUC: 0.934). Aberrant ccf-mtDNA levels could have diagnostic/prognostic potential in BrCa and Diabetes, while the developed multiparameter biosignatures can add value to their clinical management.

SIRT3 and Metabolic Reprogramming Mediate the Antiproliferative Effects of Whey in Human Colon Cancer Cells

whey; colon cancer; SIRT3; mitochondria; metabolism ACTIVATED RECEPTOR-GAMMA; COLORECTAL-CANCER; PROTEIN; EXPRESSION; APOPTOSIS Simple Summary: Colorectal cancer (CRC) is the second leading cause of cancer-related deaths and the most frequently diagnosed cancer type. CRC risk can be preventable by modifiable risk factors, including diet. This study provides evidence on the antiproliferative and pro-apoptotic effects of whey from Mediterranean water buffalo (*Bubalus bubalis*) milk in HT-29, HCT 116, LoVo, and SW480 cells. Results showed that whey induced metabolic dysfunctions and modulated the bioenergetic signature of CRC cells by targeting SIRT3 expression. These findings unveil the anti-neoplastic effects of whey and pave the way for the use of this by-product, rich in bioactive nutrients, in the setting of novel prevention strategies to reduce the risk of CRC.

Emerging strategies to improve healthy aging include dietary interventions as a tool to promote health benefits and reduce the incidence of aging-related comorbidities. The health benefits of milk are also linked to its richness in betaines and short-chain acylcarnitines, which act synergistically in conferring anticancer, anti-inflammatory, and antioxidant properties. Whey, despite being a dairy by-product, still has a considerable content of bioactive betaines and acylcarnitines. Here, we investigated the anticancer properties of whey from Mediterranean water buffalo (*Bubalus bubalis*) milk by testing its antiproliferative effects in colorectal cancer (CRC) cells HT-29, HCT 116, LoVo and SW480. Results indicated that treatment with whey for 72 h inhibited cell proliferation ($p < 0.001$), induced cell cycle arrest, and apoptosis via caspase-3 activation, and modulated cell metabolism by limiting glucose uptake and interfering with mitochondrial energy metabolism with the highest effects observed in HT-29 and HCT 116 cells. At molecular level, these effects were accompanied by upregulation of sirtuin 3 (SIRT3) ($p < 0.01$) and peroxisome proliferator-activated receptor (PPAR)- γ expression ($p < 0.001$), and downregulation of lactate dehydrogenase A (LDHA) ($p < 0.01$), sterol regulatory-element binding protein 1 (SREBP1) ($p < 0.05$), and PPAR- α ($p < 0.01$). Transient SIRT3 gene silencing blocked the effects of whey on the LDHA, PPAR- γ , and PPAR- α protein expressions ($p < 0.01$) suggesting that the whey capacity of perturbing the metabolic homeostasis in CRC cell lines is mediated by SIRT3.

 Anthony RETRACTED: Associations between Christian
 Orthodox Church Fasting and Adherence to the World Cancer Research
 Fund's Cancer Prevention Recommendations (Retracted Article)
 NUTRIENTS English Article; Retracted
 Publication fasting; cancer
 prevention; vegetarian; plant-based; fibre; Mediterranean diet
 DIET; IRON Objective: Studies regarding the health effects
 of religious fasting have increased in the last decade. The aim of
 this research was to investigate the relationship between
 Christian Orthodox Church (COC) fasting recommendations and cancer
 risk, with a specific focus on fibre, fruit, vegetables, and red
 and processed meat consumption. Methods: In this cross-sectional
 study, participants included 361 individuals from Northern Greece.
 One hundred and seventy-six participants followed the COC fasting
 regime for more than 10 years, and 185 participants did not follow
 any restrictive dietary patterns. Diet was assessed using a 114-
 item food frequency questionnaire. Results: Fasters had a more
 favourable dietary intake compared to non-fasters, with fasters
 having a higher consumption of fruit and vegetables ($p = 0.009$)
 and a significantly lower consumption of total processed meat ($p <$
 0.001) compared to non-fasters. No significant differences were
 observed in the consumption of fibre and red meat consumption
 between the two groups. Conclusions: Following the World Cancer
 Research Fund Cancer Recommendations, fasters are at a potentially
 lowering risk of developing colorectal cancer than non-fasters due
 to their more favourable dietary intake. Furthermore, higher
 consumption of fruit and vegetables with a lower consumption of
 total processed meat contributes to lower the risk of metabolic
 syndrome. Public health strategies based on following the
 structured COC fasting recommendations might hopefully contribute
 to the prevention of metabolic syndrome and colorectal cancer.

A Pilot Low-Inflammatory Dietary Intervention to Reduce Inflammation and Improve Quality of Life in Patients With Familial Adenomatous Polyposis: Protocol Description and Preliminary Results INTEGRATIVE CANCER THERAPIES English

Article FAP; hereditary tumors; low-inflammatory diet; biomarkers; microbiota; quality of life; adenomas; prevention C-REACTIVE PROTEIN; METABOLIC SYNDROME; MEDITERRANEAN DIET; ENDOTHELIAL DYSFUNCTION; MARKERS; METAANALYSIS; CONSUMPTION; ADHERENCE; PROFILES; RISK Patients with familial adenomatous polyposis (FAP) depend on a lifelong endoscopic surveillance programme and prophylactic surgery, and usually suffer nutritional problems. Intestinal inflammation has been linked to both FAP and colorectal cancer. Epidemiological studies show a relationship between diet and inflammation. Preventive dietary recommendations for FAP patients are so far lacking. We have designed a nonrandomized prospective pilot study on FAP patients to assess whether a low-inflammatory diet based on the Mediterranean diet principles and recipes, by interacting with the microbiota, reduces gastrointestinal markers of inflammation and improves quality of life. This report describes the scientific protocol of the study and reports the participants' adherence to the proposed dietary recommendations. Thirty-four FAP patients older than 18 years, bearing the APC pathogenic variant, who underwent prophylactic total colectomy with ileo-rectal anastomosis were eligible into the study. During the 3-month dietary intervention, they reported improvements in their

Antonios D. Thermal heterogeneity along the migration
corridors of sea turtles: Implications for climate change ecology
JOURNAL OF EXPERIMENTAL MARINE BIOLOGY AND ECOLOGY

English Article Adaptive
potential; Long-distance migrants; Mismatch; Mobile species;
Phenology; Species response SATELLITE TRACKING; MARINE TURTLES;
MEDITERRANEAN SEA; CARETTA-CARETTA; SHIFTS; CONSERVATION;
DISTANCE; IMPACTS; FUTURE; AREAS Increased temperatures caused by
anthropogenic climate change are becoming a major challenge for
species. In particular, species that migrate over long distances
are affected by altered climatic conditions at the various sites
they frequent and en route. Here, we investigated whether climatic
conditions experienced by sea turtles during their migration would
change in the future. We focused on the post-nesting migrations of
female loggerhead sea turtles (*Caretta caretta*) in the
Mediterranean region, to explore climatic variability along four
main migration corridors and their surrounding environment. We
also modeled the impact of earlier onset of migration, as a
potential adaptive behavioral response of Mediterranean
loggerheads. We found that over the next 80 years, sea turtles
will be exposed to significant increases in sea surface
temperatures (SSTs) along their key migration corridors and the
surrounding area (mean rate of 0.24 degrees C increase per
decade). The projected increase in SST falls outside the range of
SSTs currently reported within the examined corridors, but falls
below the threshold defined as the upper thermal limit for this
species. A highly variable climatic mosaic was identified within
the distinct segments of the corridors. We found no evidence to
support that phenological shifts might result in turtles being
exposed to climatic conditions that are similar to current levels,
in the future. Our outputs offer the first comprehensive spatial
assessment of climatic patterns along extended areas used for the
migration of sea turtles and highlight the need to quantify the
relationship between altered conditions and species physiological
and energetic status. This regional analysis could provide a
background methodological framework for mapping and assessing
spatiotemporal patterns of climatic variability along migratory
areas of marine megafauna. [Almpnidou, Vasiliki; Markantonatou,

Perception of Reproductive Health in Women with Inflammatory
Bowel Disease JOURNAL OF CROHNS & COLITIS English
Article Inflammatory bowel

disease; fertility; pregnancy; medications; cervical screening
EVIDENCE-BASED CONSENSUS; AMERICAN-CANCER-SOCIETY; PREGNANCY
OUTCOMES; CROHNS-DISEASE; PREVENTION; GUIDELINES; MANAGEMENT;
DIAGNOSIS; COHORT As inflammatory bowel diseases [IBD] affect
female patients almost exclusively during their reproductive age,
issues related to fertility, fecundity, pregnancy, delivery, and
lactation are of utmost importance. Lack of education and
misconceptions regarding the effect of disease and/or treatment on
reproductive outcome may lead to voluntary childlessness and/or
development of unwanted cervical pathologies which may impact
tremendously on patients' welfare and quality of life. The aims of
this study were to assess the perspectives of IBD patients on
fertility, pregnancy and its outcomes, and lactation, as well as
their awareness of human papillomavirus [HPV]-related pathologies
and screening for cervical cancer. This prospective study was
performed across nine different Mediterranean IBD centres between
2014 and 2015 and included consecutive female IBD patients between
the ages of 16 and 50 years. All patients responded to a
questionnaire based on ECCO guidelines. A total of 348 IBD female
patients with a mean age of 37.4 (standard deviation [SD] +/- 2.1)
years were recruited; 50% had a diagnosis of ulcerative colitis,
49.4% had Crohn's disease, and 0.6% patients had a diagnosis of
indeterminate colitis [IC]. A significant proportion of patients [
> 60%] were afraid that IBD may lead to a complicated pregnancy
and that the disease itself and/or its medications can cause fetal
harm. Patients had similar concerns that IBD can be transmitted to
their offspring as well as with regard to breastfeeding.
Counselling from health care professionals with regard to
fertility, pregnancy, and lactation was associated positively with
the highest number of pregnancies and inversely with the lowest
number of patients who considered voluntary childlessness [p <

0.0001]. Patients with a higher level of education were more likely to get pregnant [$p = 0.004$]. There was a low uptake of the HPV vaccine. However, there was a reasonably good uptake of cervical cancer screening. Our study demonstrates that women with IBD have misperceptions about fertility, pregnancy, and health maintenance. We also show that education by physicians has a positive influence. We thus conclude that improved multidisciplinary approaches should be used to educate and implement European guidelines for women with IBD. adherence to the mind diet with cognitive function and cognitive
decline in American women JOURNAL OF NUTRITION HEALTH & AGING

English Article

Cognition; dietary pattern; MIND; Mediterranean; DASH
ALZHEIMERS-DISEASE; STOP HYPERTENSION; ALPHA-TOCOPHEROL;
PATTERNS; DEMENTIA; ALLELE; CAROTENOIDS; EPSILON-4; MEMORY; RISK

There is increasing attention for dietary patterns as a potential strategy to prevent cognitive decline. We examined the association between adherence to a recently developed Mediterranean-DASH Intervention for Neurodegenerative Delay (MIND) diet with cognitive function and cognitive decline, taking into account the interaction between the apolipoprotein E epsilon 4 genotype and the MIND diet. Population-based prospective cohort study. A total of 16,058 older women aged 70 and over from the Nurses' Health Study. Dietary intake was assessed five times between 1984 and 1998 with a 116-item Food Frequency Questionnaire. The MIND score includes ten brain-healthy foods and five unhealthy foods. Cognition was assessed four times by telephone from 1995 to 2001 (baseline) with the Telephone Interview for Cognitive Status (TICS) and by calculating composite scores of verbal memory and global cognition. Linear regression modelling and linear mixed modelling were used to examine the associations of adherence to the MIND diet with average cognitive function and cognitive change over six years, respectively. Greater long-term adherence to the MIND diet was associated with a better verbal memory score (multivariable-adjusted mean differences between extreme MIND quintiles=0.04 (95%CI 0.01-0.07), p-trend=0.006), but not with cognitive decline over 6 years in global cognition, verbal memory or TICS. Long-term adherence to the MIND diet was moderately associated with better verbal memory in later life. Future studies should address this association within populations at greater risk of cognitive decline.

Oren; Shpaizer, Adi; Kanner, Joseph Lipid
Peroxidation in a Stomach Medium Is Affected by Dietary Oils
(Olive/Fish) and Antioxidants: The Mediterranean versus Western
Diet JOURNAL OF AGRICULTURAL AND FOOD CHEMISTRY

English Article stomach
medium; lipid peroxidation; olive oil; fish oil; antioxidants LOW-

DENSITY-LIPOPOTEIN; RED MEAT CONSUMPTION; FATTY-ACIDS; IN-VITRO; DIABETES-MELLITUS; COLORECTAL-CANCER; OXIDATIVE DAMAGE; PROCESSED MEAT; HEART-DISEASE; END-PRODUCTS Red meat is an integral part of the Western diet, and high consumption is associated with an increased risk of chronic diseases. Using a system that simulated the human stomach, red meat was interacted with different oils (olive/fish) and lipid peroxidation was determined by measuring accumulation of malondialdehyde (MDA) and lipid peroxides (LOOH). Olive oil decreased meat lipid peroxidation from 121.7 +/- 3.1 to 48.2 +/- 1.3 μ M and from 327.1 +/- 9.5 to 77.3 +/- 6.0 μ M as assessed by MDA and ROOH, respectively. The inhibitory effect of olive oil was attributed to oleic acid rather than its polyphenol content. In contrast, fish oils from tuna or an omega-3 supplement dramatically increased meat lipid peroxidation from 96.2 +/- 3.6 to 514.2 +/- 6.7 μ M MDA. Vitamin E inhibited meat lipid peroxidation in the presence of olive oil but paradoxically increased peroxidation in the presence of fish oil. The inhibitory properties of oleic acid may play a key role in the health benefits of the Mediterranean diet. J Jakobovich, R; Berry, EM; Levita, A; Levin-Zamir, D
Jakobovich, Ronit; Berry, Elliot M.; Levita, Asia; Levin-Zamir, Diane Developing Healthy
Lifestyle Behaviors in Early Age-An Intervention Study in Kindergartens NUTRIENTS English Article
early childhood; parents; healthy nutrition; kindergarten intervention; Mediterranean lifestyle change; mixed-methods; mathematical-logical thinking; health literacy FOOD-CONSUMPTION PATTERNS; BODY-MASS INDEX; PRESCHOOL-CHILDREN; VEGETABLE INTAKE; OBESITY; PREVENTION; FAMILY; IMPACT; FRUIT; DIET Childhood obesity prevention is a leading public health challenge requiring the adoption of healthy lifestyles at an early age. We examined how the kindergarten environment can promote eating sensibly, drinking water and becoming physically active. The effects of an intervention program among 42 Israeli kindergartens (1048 children, aged 4-6) whose teachers participated in a health education training program were compared to 32 kindergartens (842 children) whose teachers did not undergo this training program. An eight-month intervention program focused on knowledge/mathematical/logical/critical thinking, self-regulation/control acquisition, and sensible decision-making abilities. We hypothesized that nutrition and physical-exercise-

oriented intervention programs, combining knowledge/mathematical logical thinking, would positively impact the quality of children's mid-morning snack and water consumption, their ability to express feelings following physical exercise, and the adoption of healthy lifestyles at home. The quality of mid-morning snacks and water consumption were observed in both groups pre- and post-intervention. Qualitative interviews documented children's subjective feelings following physical exercise. A significant improvement ($p < 0.001$) was observed in the mid-morning snacks composition and in water drinking habits in the intervention group; 80% of children offered a physiological explanation regarding energy expenditure processes following intense physical exercise. In conclusion, kindergarten interventions implemented by trained teachers can promote adoption of health behaviors necessary for obesity prevention. Zhang, Ting; Naudin, Sabine; Hong, Hyokyung G.; Albanes, Demetrius; Mannisto, Satu; Weinstein, Stephanie J.; Moore, Steven C.; Stolzenberg-Solomon, Rachael Z. Dietary Quality and Circulating Lipidomic Profiles in 2 Cohorts of Middle-Aged and Older Male Finnish Smokers and American Populations JOURNAL OF NUTRITION English Article

alternate Mediterranean diet; alternative Healthy Eating Index; fatty acid; Healthy Eating Index; lipidomics; lipid species HEALTHY EATING INDEX; CARDIOVASCULAR-DISEASE; RISK; PATTERN; SUPPLEMENTATION; QUESTIONNAIRE; METABOLOMICS; BIOMARKERS; MARKERS; UPDATE Background: Higher dietary quality is associated with lower disease risks and has not been examined extensively with lipidomic profiles. Objectives: Our goal was to examine associations of the Healthy Eating Index (HEI)-2015, Alternate HEI-2010 (AHEI-2010), and alternate Mediterranean Diet Index (aMED) diet quality indices with serum lipidomic profiles. Methods:

We conducted a cross-sectional analysis of HEI-2015, AHEI-2010, and aMED with lipidomic profiles from 2 nested case-control studies within the Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial (n = 627) and the Alpha-Tocopherol, Beta-Carotene Cancer Prevention Study (n = 711). We used multivariable linear regression to determine associations of the indices, derived from baseline food-frequency questionnaires (Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial: 1993-2001, Alpha-Tocopherol, Beta-Carotene Cancer Prevention Study: 1985-1988) with serum concentrations of 904 lipid species and 252 fatty acids (FAs) across 15 lipid classes and 28 total FAs, within each cohort and metaanalyzed results using fixed-effect models for lipids significant at Bonferroni-corrected threshold in common in both cohorts. Results: Adherence to HEI-2015, AHEI-2010, or aMED was associated positively with 31, 41, and 54 lipid species and 8, 6, and 10 class-specific FAs and inversely with 2, 8, and 34 lipid species and 1, 3, and 5 class-specific FAs, respectively. Twenty-five lipid species and 5 class-specific FAs were common to all indices, predominantly triacylglycerols, FA22:6 [docosahexaenoic acid (DHA)]-containing species, and DHA. All indices were positively associated with total FA22:6. AHEI-2010 and aMED were inversely associated with total FA18:1 (oleic acid) and total FA17:0 (margaric acid), respectively. The identified lipids were most associated with components of seafood and plant proteins and unsaturated:saturated fat ratio in HEI-2015; eicosapentaenoic acid plus DHA in AHEI-2010; and fish and monounsaturated:saturated fat ratio in aMED. Conclusions: Adherence to HEI-2015, AHEI-2010, and aMED is associated with serum lipidomic profiles, mostly triacylglycerols or FA22:6-containing species, which are related to seafood and plant proteins, eicosapentaenoic acid-DHA, fish, or fat ratio index components. Diet, obesity, and the gut microbiome as
determinants modulating metabolic outcomes in a non-human primate
model MICROBIOME English Article

Metagenomic sequencing; Metabolomics; Western and
Mediterranean diet; Body fat composition; *Prevotella copri*;
Eubacterium siraeum; Urinary carnitine metabolites; Uremic toxins

Background: The objective of this study was to
increase understanding of the complex interactions between diet,
obesity, and the gut microbiome of adult female non-human primates
(NHPs). Subjects consumed either a Western (n=15) or Mediterranean
(n=14) diet designed to represent human dietary patterns for 31
months. Body composition was determined using CT, fecal samples
were collected, and shotgun metagenomic sequencing was performed.
Gut microbiome results were grouped by diet and adiposity.

Results: Diet was the main contributor to gut microbiome bacterial
diversity. Adiposity within each diet was associated with subtle
shifts in the proportional abundance of several taxa.

Mediterranean diet-fed NHPs with lower body fat had a greater
proportion of *Lactobacillus animalis* than their body fat
counterparts. Higher body fat Western diet-fed NHPs had more
Ruminococcus champaneliensis and less *Bacteroides* uniformis than
their low body fat counterparts. Western diet-fed NHPs had
significantly higher levels of *Prevotella copri* than Mediterranean
diet NHPs. Western diet-fed subjects were stratified by *P. copri*
abundance (*P. copri*(HIGH) versus *P. copri*(LOW)), which was not
associated with adiposity. Overall, Western diet-fed animals in
the *P. copri*(HIGH) group showed greater proportional abundance of
B. ovatus, *B. faecis*, *P. stercora*, *P. brevis*, and
Faecalibacterium prausnitzii than those in the Western *P.*
copri(LOW) group. Western diet *P. copri*(LOW) subjects had a
greater proportion of *Eubacterium siraeum*. *E. siraeum* negatively
correlated with *P. copri* proportional abundance regardless of
dietary consumption. In the Western diet group, Shannon diversity

was significantly higher in P. copri(LOW) when compared to P. copri(HIGH) subjects. Furthermore, gut E. siraeum abundance positively correlated with HDL plasma cholesterol indicating that those in the P. copri(LOW) population may represent a more metabolically healthy population. Untargeted metabolomics on urine and plasma from Western diet-fed P. copri(HIGH) and P. copri(LOW) subjects suggest early kidney dysfunction in Western diet-fed P. copri(HIGH) subjects. Conclusions: In summary, the data indicate diet to be the major influencer of gut bacterial diversity. However, diet and adiposity must be considered together when analyzing changes in abundance of specific bacterial taxa. Interestingly, P. copri appears to mediate metabolic dysfunction in Western diet-fed NHPs. PREVENTIVE MEDICINE English Article

Health behavior; Lifestyle;

Mediterranean diet; Physical exercise; Smoking; Obesity; Abdominal obesity PHYSICAL-ACTIVITY QUESTIONNAIRE; CORONARY-HEART-DISEASE; BODY-FAT DISTRIBUTION; MEDITERRANEAN DIET; COLORECTAL-CANCER; NORFOLK COHORT; ALCOHOL INTAKE; WEIGHT CHANGE; MASS INDEX; WOMEN Background: Diet, smoking and physical activity are important modifiable lifestyle factors that can influence body weight and fat accumulation. We assessed the relationship between lifestyle and obesity risk in a baseline analysis of the PREDIMED study, a randomized dietary primary prevention trial conducted in Spain. Methods: 7000 subjects at high cardiovascular risk were assessed cross-sectionally. A healthy lifestyle pattern (HLP) was determined using a score including: adherence to the Mediterranean diet, moderate alcohol consumption, expending ≥ 200 kcal/day in leisure-time physical activity, and non-smoking. Results: Inverse linear trends were observed between the HLP-score and body-mass-index (BMI) or waist circumference ($p < 0.001$). The BMI and waist circumference of participants with a HLP-score=4 were, respectively, 1.3 kg/m² (95% CI: 0.9 to 1.7) and 4.3 cm (3.1 to 5.4) lower than those of subjects with an HLP The odds ratios of general obesity and abdominal obesity for an HLP score of 4 compared to an HPL score ≤ 1 were 0.50 (0.42 to 0.60) and 0.51 (0.41 to 0.62), respectively Conclusion: A combination of four healthy lifestyle behaviors was associated with a lower prevalence of general obesity and abdominal obesity in Mediterranean elderly subjects at high cardiovascular risk. Elisabeth Spatial Assimilation at a Halt?

Intergenerational Persistence in Neighborhood Contexts among
Immigrant Minorities in Norway INTERNATIONAL MIGRATION REVIEW
English Article

immigrant assimilation; contextual mobility; neighborhood attainment ETHNIC SEGREGATION; MOBILITY; TRANSMISSION; POVERTY; DISCRIMINATION; COMMUNITIES; INTEGRATION; POPULATION; ATTAINMENT; INEQUALITY Spatial assimilation theory claims that immigrants' acculturation and socioeconomic progress will lead to converging neighborhood attainment relative to non-migrant natives. Recently, it has been argued that equalization of local services and life chances across neighborhoods in egalitarian welfare states may delay spatial assimilation by reducing immigrants' incentives to move out of low-income areas with many (co-ethnic) immigrant neighbors. In this article, we extend this argument to study whether neighborhood equalization also contributes to intergenerational persistence in neighborhood contexts among descendants of immigrants in Norway. Using administrative data, we find that immigrant descendants as adults often remain in neighborhood contexts that resemble their childhood neighborhoods, characterized by relative economic disadvantage and comparatively few ethnic majority residents. Intergenerational persistence in neighborhood contexts is strongest among descendants of immigrants from Pakistan, the Middle East, and Africa. The remaining immigrant-native gaps in spatial economic inequality largely reflect differences in individuals' education and earnings, family background, and childhood neighborhood context, but these factors matter less for ethnic neighborhood segregation. For both economic and ethnic dimensions of neighborhood attainment, childhood neighborhood context is the factor that matters most in accounting for immigrant-native gaps, whereas individual socioeconomic attainment is the least important. Overall, our findings point to a pattern of "uneven assimilation" among immigrant descendants, where spatial assimilation is slow despite rapid socioeconomic

progress across immigrant generations in the egalitarian Norwegian welfare state. Frequency and genotyping of human papillomavirus in
patients with DNA tracking technique during 1996-99 ROMANIAN
JOURNAL OF MILITARY MEDICINE English Article

human papillomavirus; frequency;
genotype; DNA tracking technique CERVICAL-CANCER; E-CADHERIN;
MICRORNA; TYPE-16; TRANSFORMATION; EXPRESSION; MOUSE; CELLS;
PAPILLOMATOSIS; PROLIFERATION The prevalence of human
papillomavirus (HPV) infections and their role in cervical cancer
have been well documented in numerous articles, but it seems that
a study in this field in developing countries and the Middle East,
including Iran. It's not done. Therefore, the present study was
designed and performed to investigate the frequency and genotyping
of human papillomavirus in patients by DNA tracking technique.
This study was a population-based study in which the frequency and
genotyping of human papillomavirus in patients by tracking
technique was designed and performed on 534 men and women living
in Tehran by DNA tracking technique. Sequences obtained using the
NCBI site were analyzed at

(http://www.ncbi.nlm.nih.gov/BLAST/LaserGene) and Bio edit
software. So that in three low-risk groups including 6 and 11
genotypes, Intermediate risk includes 26-31-33-35-39-40-42-45-49-
51- 52-53 genotypes -55-56-58-59-66-63-83 and High risk includes
16 & 18 genotypes were divided. According to the results, the
prevalence of the papilloma virus in the study population was
21.16%, of which 19.46% were in the high-risk group, 69.89% were
in the intermediate-risk group and 50.43% were in the low-risk
group. According to the results of the present study, although the
prevalence of HPV in the study population is less than in many
countries in the world, it is suggested that conducting

epidemiological studies in the country to extract the true prevalence and plan to prevent and control this disease. Knowledge of Human Papillomavirus and Acceptability to
Vaccinate in Adolescents and Young Adults of the Moroccan
Population JOURNAL OF PEDIATRIC AND ADOLESCENT GYNECOLOGY
English Article

Human papillomavirus vaccine; Adolescents; Knowledge;
Acceptability EXTENDED MIDDLE-EAST; CERVICAL-CANCER; HPV
VACCINE; SCHOOL-STUDENTS; AWARENESS; WOMEN; INFECTIONS; ATTITUDES;
BURDEN Study Objective: Human papillomavirus (HPV) infection
is estimated to play an etiologic role in 99.7% of cervical
cancer. Vaccines can prevent up to 70% of the cervical cancer
caused by HPV 16 and 18. The present study was designed to define
the knowledge of HPV and HPV vaccine acceptability among Moroccan
youth. Design, Setting, Participants, Interventions, and Main
Outcome Measures: A nationwide anonymous questionnaire with a
sample of 688 adolescents (12-17 years) and 356 young adults (18-
30 years) was organized, that asked about HPV, origin of cervical
cancer, Papanicolaou (Pap) test, and acceptability of HPV vaccine.
Data were analyzed using univariate and multivariate logistic
regression methods. Results: Overall, a low frequency (213/1044 =
20%) of HPV knowledge was observed among the studied population. A
multivariate model analysis showed that age, educational level,
and knowledge of the Pap test remained significantly associated
factors with HPV knowledge. Additionally, only 27% (282/1044) of
participants were willing to accept HPV vaccination. Highest
acceptability was observed among young adults compared with
adolescents (166/356 = 46.6% vs 116/688 = 16.9%). Sixty-two
percent (103/165) of male participants accepted the HPV vaccine
compared with only 20.4% (179/879) of female participants.
Educational level, type of school, and knowledge of the Pap test
were associated factors with HPV vaccine acceptability in a
multivariate model analysis. Conclusion: The present study showed
a low level of HPV knowledge and HPV vaccine acceptability among
Moroccan youth. Promotion of activities and sensitization are
required to maximize public awareness in the future. This
objective can be achieved with the use of media, active efforts by
health care providers, and introduction of sexual education in

school programs. HEALTHY EATING INDEX; MEDITERRANEAN DIET; BREAST-CANCER;
GLYCEMIC LOAD; FRUIT INTAKE; METAANALYSIS; PATTERNS;
REPRODUCIBILITY; CONSUMPTION; MORTALITYObjectiveMost previous
studies investigated the associations between intake of individual
nutrients and risk of disease, which failed to consider the
potential interactions and correlations between various nutrients
contained in food. Although dietary quality scores provide a
comprehensive evaluation of the entire diet, it remains elusive
whether they are associated with the risk of pancreatic
cancer.MethodsDietary intake data collected with the Dietary
Questionnaire (DQX) and Diet History Questionnaire (DHQ) were used
to calculate HEI-2015 and DQI-R scores for participants in the
Prostate, Lung, Colorectal and Ovarian (PLCO) Cancer Screening
Trial. A high score indicates an increased intake of adequacy
components and a decreased intake of moderation components. This
study included 252 cases of pancreatic cancer documented from
58,477 persons during a median follow-up of 12.2 years in the DQX
cohort and 372 cases of pancreatic cancer ascertained from 101,721
persons during a median follow-up of 8.9 years in the DHQ cohort.
Cox proportional hazards regression analysis was performed to
calculate hazard ratios (HR) and 95% confidence intervals (CI) for
the associations between the two dietary quality scores and
pancreatic cancer risk.ResultsAfter adjustment for confounders,
HEI-2015 and DQI-R scores were not significantly associated with
pancreatic cancer risk. However, a significantly lower risk was
observed for overweight persons with a higher HEI-2015 score in
the DQX cohort (HR [95% CI] comparing the highest with lowest
tertile: 0.52 [0.32, 0.85], p for trend = 0.009) and those with
higher scores of some individual
components.ConclusionCollectively, overall dietary quality is not

associated with an altered risk of pancreatic cancer in this US population. Previous studies evaluating the roles of individual nutrients in the etiology of pancreatic cancer fails to consider the potential interactions and correlations between various nutrients contained in food. We investigated the associations between overall dietary quality scores (HEI-2015 and DQI-R) and pancreatic cancer risk in a large prospective cohort study. The findings of this study can help inform a novel and practical approach to primary prevention of this deadly disease through dietary modification and intervention. Exploring an herbal "wonder cure" for cancer: a multidisciplinary approach JOURNAL OF CANCER RESEARCH AND CLINICAL ONCOLOGY English Article

Integrative medicine; Herbal medicine; Complementary medicine; Quality-of-life (QOL); Drug-herb interactions; Ephedra foeminea ARAB PATIENTS; MEDICINE; ONCOLOGY; COMPLEMENTARY; PERSPECTIVES; ISRAEL; CARE; QUACKERY; EPHEDRA; HEALTH The unmonitored use of herbal medicinal remedies by patients with cancer presents a significant challenge to oncology healthcare professionals. We describe an increasingly popular herbal "wonder drug," Ephedra foeminea (Alanda in Arabic), whose use has spread from the Palestinian patient population throughout the Middle East. We conducted a multicentered and

multidisciplinary collaborative research effort in order to understand the potential benefits and harms of this popular herbal remedy. We conducted an in-depth search of the medical literature, both traditional and modern, for any mention of the clinical use of Alanda for the treatment of cancer. We then tested the remedy, first for toxic ephedra alkaloid components and then for anticancer effects, as well as effects on the cytotoxic activity of chemotherapy agents (cisplatin and carboplatin) on breast cancer cell cultures. We found no mention in the literature, both conventional and traditional, on the use of Alanda for the treatment of cancer. Laboratory testing did not find any toxic components (i.e., ephedra alkaloids) in the preparation. However, in vitro exposure to Alanda led to a reduced cytotoxic effect of chemotherapy on breast cancer cell cultures. The use of an integrative ethnobotanical, laboratory and clinical research-based approach can be extremely helpful when providing nonjudgmental and evidence-based guidance to patients with cancer, especially on the use of traditional herbal medicine. The effectiveness and safety of these products need to be examined by integrative physicians who are dually trained in both complementary medicine and supportive cancer care.

 Kenneth L. Psychosocial factors associated with diet
 quality in a working adult population RESEARCH IN NURSING &
 HEALTH English Article

diet quality; diet patterns; AHEI; DASH; Mediterranean
 diet; psychosocial CORONARY-HEART-DISEASE; FAMILY ASSESSMENT
 DEVICE; DASH EATING PLAN; STOP HYPERTENSION; VEGETABLE
 CONSUMPTION; MEDITERRANEAN DIET; METABOLIC SYNDROME; COLORECTAL-
 CANCER; PHYSICAL-ACTIVITY; PERCEIVED STRESS The associations
 between specific intra- and inter-personal psychosocial factors
 and dietary patterns were explored in a healthy, working adult
 sample of university and health center employees (N=640) who were
 enrolled in a prospective predictive health study. Participants
 had a mean age of 48 (SD=11) years and were 67% women and 30%
 minority. Baseline psychosocial measures of perceived stress,
 depressive symptoms, social support, and family functioning were
 examined for their relationships with three diet quality
 indices AHEI, DASH, and the Mediterranean. Dietary intake was of
 moderate quality in this high-income, well-educated,
 psychosocially healthy population. Social support was positively
 associated with better diet quality for all three indices ($p < .01$).
 Further research should focus on socio-environmental factors
 associated with diet quality. (c) 2013 Wiley Periodicals, Inc. Res

J Erdogan, BZ; Umut, MÖ Erdogan, Bayram
Zafer; Umut, Meftune Ozbakir An overview of social
marketing in Türkiye SOCIAL MARKETING QUARTERLY
English Article; Early Access

social marketing; inequality in education; violence against women; T & uuml;rkiye CONTEXT Background of the Country The Republic of T & uuml;rkiye, is a transcontinental country located in East Thrace in south-eastern Europe and on the peninsula of Anatolia in southwestern Asia. With the collapse of the Ottoman Empire, which was an immense power in Eurasia and Africa from southeast Europe to western Asia and North Africa, and the proclamation of the Republic in 1923, the Turkish people gained the right to self-government for the first time in centuries. With an amendment to the Constitution of the Republic, T & uuml;rkiye became governed by a new system in which the president has executive powers. T & uuml;rkiye ranked 48th out of 191 countries in the 2022 Human Development Index. Primary social Problems in the Country Unemployment has been a major socio-economic problem in T & uuml;rkiye. Other important social issues include the integration of irregular migrants into social life, education inequality, violence against women, and forest fires. Use of Social Marketing Although they have not been found to be sufficient to solve the fundamental social problems there are projects that have been carried out in T & uuml;rkiye for many years. These projects are corporate social responsibility initiatives that focus on market research to solve a fundamental social problem, in a select target market in a bid to change behavior through effective communication. Academic Stakeholders and Activities The few social marketing projects carried out in T & uuml;rkiye have been funded by marketing academics and have focused primarily on the development of environmentally friendly behaviors. Social marketing courses are included in the curricula of a small number of universities in T & uuml;rkiye. It can be stated that the concept of social marketing in T & uuml;rkiye is not clearly understood by practitioners. However, efforts to develop behavior change for the benefit of society seem to have started with charity and evolved into corporate social responsibility projects. Discussion and Conclusions Despite not being deemed sufficient to solve the fundamental social problems, there are projects that have been ongoing in T & uuml;rkiye for many years. These projects are corporate social responsibility initiatives aimed at addressing crucial social issues. Social marketing has

been used in T & uuml;rkiye for four decades but still has not achieved its full potential. Because social marketing is a concept similar to the understanding of the philanthropy that existed in Turkish culture many centuries ago, it can easily be adapted to the Turkish market. It is recommended that the government of T & uuml;rkiye use social marketing to promote behavioral practices that benefit society. J Behrouj, H; Mahmoudzadeh, A; Ghavami, S; Mokarram, P
 Behrouj, Hamid; Mahmoudzadeh, Amir; Ghavami, Saeid; Mokarram, Pooneh Autophagy Flux Correlates with Upregulation of AKT-1 in RAS Mutated Colon Cancer Cells

MIDDLE EAST JOURNAL OF CANCER English
 Article Colorectal cancer; RAS oncogene; Autophagy; AKT/PKB kinase KINASE; PROLIFERATION; INHIBITION; SURVIVAL; PATHWAY; KRAS Background: The AKT/PKB (protein kinase B) kinase is the main regulator of autophagy in mammalian cells, which consists of three isoforms, including AKT-1, AKT-2, and AKT-3. Rat sarcoma viral oncogene homolog (RAS), known as the most frequently mutated oncogene in colorectal cancers, is one of the major activators of AKT signaling. However, the relationship between AKT isoforms expression and autophagy level in RAS-driven cancer cells has not been fully investigated. Method: In this experimental in vitro study, RAS mutated colon cancer cell lines (HCT116, SW480, and LS180) and HT29 cells, which are the wild type of RAS, were cultured and real-time polymerase chain reaction (RT-PCR) was utilized to determine the mRNA level of AKT-1, AKT-2, and autophagy markers, including microtubule-associated protein 1 light chain-3B (LC3B) and p62/sequestosome-1 (p62). In addition, Western blotting was performed to assess the protein expression of p62 and LC3B lipidation. Results: We found that RAS mutated colon cancer cells up-regulate basal autophagy. Moreover, highly expressed AKT-1 was observed in RAS mutated colon cancer cells. However, no significant differences were found in AKT-2 expression between RAS-driven cells and HT29 cells. Conclusion: Our obtained data suggested that RAS-driven colon cancer cells regulated the autophagy machinery, possibly, through the upregulation of AKT-1 isoform. [Behrouj, Hamid;

Nutrition, oxidative stress and intestinal dysbiosis:

Influence of diet on gut microbiota in inflammatory bowel diseases
BIOMEDICAL PAPERS-OLOMOUC English Article

inflammatory bowel diseases;

colorectal cancer; intestinal dysbiosis; gut microbiota; healthy diet IBD; PATHOGENESIS; HYPOTHESIS; HEALTH Background.

Microbiota refers to the population of microorganisms (bacteria, viruses and fungi) that inhabit the entire gastrointestinal tract, more particularly the colon whose role is to maintain the integrity of the intestinal mucosa and control the proliferation of pathogenic bacteria. Alteration in the composition of the gut microbiota is called dysbiosis. Dysbiosis predisposes to inflammatory bowel diseases such as ulcerative colitis, Crohn disease and indeterminate colitis. Methods. The purpose of this literature review is to elucidate the influence of diet on the composition of the gastrointestinal microbiota in the healthy gut and the role of diet in the development of dysbiosis. Conclusion. The "Western diet", in particular a low - fiber high fat/high carbohydrate diet is one factor that can lead to severe dysbiosis. In contrast, "mediterranean" and vegetarian diets that includes abundant fruits, vegetables, olive oil and oily fish are known for their anti-inflammatory effects and could prevent dysbiosis and subsequent inflammatory bowel disease. J Cailhol, J; Khan, N Cailhol, Johann;
Khan, Nichola Chronic hepatitis and HIV risks
amongst Pakistani migrant men in a French suburb and insights into
health promotion interventions: the ANRS Musafir qualitative study
BMC PUBLIC HEALTH English Article

Migration; Pakistan; Europe; Hepatitis
C; HIV; Risk; Vulnerability; Qualitative study; Health promotion
C VIRUS; PREVALENCE; COMMUNITY; INFECTION; WORKING; ABUSE;
PART Background Seine-Saint-Denis is a deprived departement
(French administrative unit) in the North-East of Paris, France,
hosting the majority of South Asian migrants in France. In recent
years, the number of migrants from Pakistan, which has a high
prevalence of hepatitis C globally, increased. As a corollary,
this study addressed the high proportion of Pakistani patients in
the infectious diseases clinic of a local hospital, diagnosed with
hepatitis C, but also hepatitis B and Human Immunodeficiency Virus
(HIV). It explored genealogies and beliefs about hepatitis and HIV
transmission, including community, sexual and blood risk
behaviours. The aim was to understand the ways these risk factors
reduce or intensify both route and once in France, in order to
devise specific forms of community health intervention. Methods
The study took place at Avicenne University-Hospital in Seine-
Saint-Denis, and its environs, between July and September 2018.
The design of the study was qualitative, combining semi-structured
interviews, a focus group discussion, and ethnographic
observations. The sample of Pakistani participants was selected

from those followed-up for chronic hepatitis C, B, and/or HIV at Avicenne, and who had arrived after 2010 in Seine-Saint-Denis. Results Thirteen semi-structured interviews were conducted, until saturation was reached. All participants were men from rural Punjab province. Most took the Eastern Mediterranean human smuggling route. Findings suggest that vulnerabilities to hepatitis and HIV transmission, originating in Pakistan, are intensified along the migration route and perpetuated in France. Taboo towards sexuality, promiscuity in cohabitation conditions, lack of knowledge about transmission were amongst the factors increasing vulnerabilities. Participants suggested a number of culturally-acceptable health promotion interventions in the community, such as outreach awareness and testing campaigns in workplaces, health promotion and education in mosques, as well as web-based sexual health promotion tools to preserve anonymity. Conclusions Our findings highlight the need to look at specific groups at risk, related to their countries of origin. In-depth understandings of such groups, using interdisciplinary approaches such as were employed here, can allow for culturally adapted, tailored interventions. However, French colour-blind policies do not easily permit such kinds of targeted approach and this limitation requires further debate.

Megeressa, Mekdes; Siraj, Bushra; Zarina, Shamshad; Ahmed, Aftab Structural characterization and in vitro lipid binding studies of non-specific lipid transfer protein 1 (nsLTP1) from fennel (*Foeniculum vulgare*) seeds SCIENTIFIC REPORTS

English Article

LIGAND-BINDING; SUSCEPTIBILITY; EXPRESSION; INHIBITOR;
 PEPTIDE; SYSTEM; MEMBER; RICE Non-specific lipid transfer
 proteins (nsLTPs) are cationic proteins involved in intracellular
 lipid shuttling in growth and reproduction, as well as in defense
 against pathogenic microbes. Even though the primary and spatial
 structures of some nsLTPs from different plants indicate their
 similar features, they exhibit distinct lipid-binding
 specificities signifying their various biological roles that
 dictate further structural study. The present study determined the
 complete amino acid sequence, in silico 3D structure modeling, and
 the antiproliferative activity of nsLTP1 from fennel (*Foeniculum
 vulgare*) seeds. Fennel is a member of the family Umbelliferae
 (Apiaceae) native to southern Europe and the Mediterranean region.
 It is used as a spice medicine and fresh vegetable. Fennel nsLTP1
 was purified using the combination of gel filtration and reverse-
 phase high-performance liquid chromatography (RP-HPLC). Its
 homogeneity was determined by sodium dodecyl sulfate
 polyacrylamide gel electrophoresis (SDS-PAGE) and matrix-assisted
 laser desorption/ionization-time of flight (MALDI-TOF) mass
 spectrometry. The purified nsLTP1 was treated with 4-vinyl
 pyridine, and the modified protein was then digested with trypsin.
 The complete amino acid sequence of nsLTP1 established by intact
 protein sequence up to 28 residues, overlapping tryptic peptides,
 and cyanogen bromide (CNBr) peptides. Hence, it is confirmed that
 fennel nsLTP1 is a 9433 Da single polypeptide chain consisting of
 91 amino acids with eight conserved cysteines. Moreover, the 3D
 structure is predicted to have four alpha -helices interlinked by
 three loops and a long C-terminal tail. The lipid-binding property
 of fennel nsLTP1 is examined in vitro using fluorescent 2-p-
 toluidinonaphthalene-6-sulfonate (TNS) and validated using a
 molecular docking study with AutoDock Vina. Both of the binding
 studies confirmed the order of binding efficiency among the four
 studied fatty acids linoleic acid>linolenic acid>Stearic
 acid>Palmitic acid. A preliminary screening of fennel nsLTP1
 suppressed the growth of MCF-7 human breast cancer cells in a
 dose-dependent manner with an IC50 value of 6.98 μ M after 48 h
 treatment. [Megeressa, Mekdes; Ahmed, Aftab] Chapman Univ, Sch

J Dany, M; Chidiac, A; Nassar, AH Dany,
Mohammed; Chidiac, Alissar; Nassar, Anwar H. Human
papillomavirus vaccination: Assessing knowledge, attitudes, and
intentions of college female students in Lebanon, a developing
country VACCINE English Article

HPV vaccination; HPV infection; Student
knowledge; Student attitudes; Student intentions; Developing
country EXTENDED MIDDLE-EAST; HPV VACCINATION; YOUNG-WOMEN;
AWARENESS; EPIDEMIOLOGY; ADOLESCENTS; INFECTIONS; BURDENHuman
papillomavirus (HPV) infection is a common cause for genital warts
and cervical cancer. Developing countries in the Middle East such
as Lebanon are traditionally considered to be conservative
societies with low incidence of sexually transmitted infections.
However, nowadays, there is an unexpected increase in the
incidence of HPV infections among Middle Eastern females. Thus,
the objective of this study is to assess the behavioral
perceptions of HPV vaccination among female students attending an
academic institution in Lebanon. This cross-sectional study
invited 512 students to complete a self-administered questionnaire
that assessed the knowledge, attitudes, and intentions towards HPV
vaccination. Data analysis included the calculation of knowledge
scores ranging from 0 to 100, attitude scores ranging from most
positive (1) to most negative (5), and intention scores ranging
from lowest intention (0) to highest intention (10). With a
response rate of $n = 215$ (42%), 36.5% never heard of the vaccine
before, and only 16.5% were already HPV vaccinated. The median
knowledge score of $52.7\% \pm 11.71$ reflects poor to moderate
knowledge. Still, the median attitude score of 2.47 ± 0.05 shows
a general positive attitude towards HPV vaccination where most of
the participants agreed that female college students in Lebanon
have a good chance of contracting HPV (62.1%) and that all
gynecologists should recommend the vaccine (76.0%). Students in
graduate programs, health related majors, and those who are
vaccinated had significantly higher knowledge scores compared with
students in undergraduate programs, non-health related majors, and
HPV non-vaccinated students, respectively. Finally, the survey
helped in increasing the intention to obtain HPV vaccine as the
intention score increased significantly from 5.24 ± 0.27 before
the students went through the survey to 6.98 ± 0.22 after the
students completed the survey. Our study highlights the importance
of offering guidance to female college students about HPV and its
vaccination in developing countries where the incidence of
sexually transmitted infections is on the rise. (C) 2015 Elsevier

 Curcumin Nano-micelle on Proliferation and Apoptosis of HT29 and
 Hct116 Colon Cancer Cell Lines MIDDLE EAST JOURNAL OF CANCER
 English Article
 Colonic neoplasms; Cell proliferation; Apoptosis; Curcumin
 TELOMERASE Background: Curcumin is a natural polyphenolic
 material with antioxidative, anti-inflammatory, and anticancer
 effects. In this study, we attempted to assay antiproliferative
 and apoptotic properties of polymeric micelles of curcumin on two
 colorectal cancer cell lines and normal human fibroblast cells.
 Method: In this experimental study, cancer cells HT29, HCT116 and
 normal human fibroblast cells (HGF) were subjected to
 concentrations of Nanocurcumin (1, 50, 100, 250, and 500 μ g/ml).
 After incubation for 48 hours, cell viability was assessed with
 "MTT" (3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium
 bromide) assay. Annexin V-FITC and Propidium iodide staining were
 done with flow cytometry for evaluation of apoptosis. The results
 were shown as mean $\pm$ standard deviation. Statistical
 significance was assessed utilizing ANOVA and Dunnetts t-test ($P < 0.01$).
 Results: According to MTT (3-(4,5-dimethylthiazol-2-yl)-
 2,5-diphenyltetrazolium bromide) assay results, IC50 value of
 Nanocurcumin in HT29, HCT116, and HGF were 70.63, 123.9, and
 168.53 μ g/ml, respectively. We also discovered that Nanocurcumin
 can make indicative apoptosis in cancer cells, which could be
 compared with cisplatin <0.01 . Conclusion: These results revealed
 remarkable antiproliferative and apoptotic effects of polymeric
 Nano-micelles of curcumin in colorectal cancer cell lines.

Chemical Profiling and Bioactivity Assessment of *Helichrysum italicum* (Roth) G. Don. Essential Oil: Exploring Pure Compounds and Synergistic Combinations

English

Article

breast cancer cell

lines; MDA-MB-231; human dermal fibroblast; HDF; lung cell lines; BEAS-2B; MTS and MTT assay; *Helichrysum italicum* (Roth) G; Don; immortelle; SEM IN-VITRO; ANTIMICROBIAL ACTIVITY; ANTIOXIDANT; ASTERACEAE; APOPTOSIS; TRICHOMES; FLOWERS; GLANDS; LEAVES

Helichrysum italicum (Roth) G. Don., immortelle, is a plant species used in ethnomedicine and the food industry as a spice added to food, beverages, and bakery products. It has been shown to possess various biological activities, such as antioxidant and antibacterial activity, making it useful as a natural preservative. We investigated the phytochemical profile and biological activity of *H. italicum* essential oils from wild-grown plant material collected from natural habitats in the Republic of Croatia and Bosnia and Herzegovina. Using high-resolution scanning electron microscopy (SEM), a visual investigation of plant organs (stem, leaf, and flower) was performed, confirming the presence of essential oil reservoirs on the surface of all examined plant organs. Essential oils were isolated by hydrodistillation in the Clevenger apparatus. The chemical composition of the essential oils was determined using the GC-MS analytical technique. Cytotoxic activity tests were performed in vitro on three cell lines: skin (fibroblast), lung, and breast cancer. Using statistical tools, the synergistic and selective effects of *H. italicum* essential oil on healthy and tumor cells were correlated to chemical composition and cytotoxic activity. The synergistic and antagonistic effects of *H. italicum* essential oil's individual components were simulated by testing pure compounds and their mixture of cytotoxic activity on fibroblasts and breast cancer cells. The results confirm that essential oil's biological activity is much greater than the sum of the effects of its components. The present data are novel contributions to the body of knowledge on the biological activity of this species used in the food industry. J Saechan, V; Settheetham-Ishida, W; Kimura, R; Tiwawech, D; Mitarnun, W; Ishida, T Saechan, Vannarat; Settheetham-Ishida, Wannapa; Kimura, Ryosuke; Tiwawech, Danai; Mitarnun, Winyou; Ishida, Takafumi Epstein-Barr virus strains defined by the latent membrane protein 1 sequence characterize Thai ethnic groups JOURNAL OF GENERAL VIROLOGY English Article

NASOPHARYNGEAL CARCINOMA; JC VIRUS; T-CELL; LMP1; DNA; DELETION; MEMBRANE-PROTEIN-1; EVOLUTION; ALIGNMENT; VARIANTS Epstein-Barr virus (EBV) is ubiquitous in the human population and seroepidemiological studies have revealed that more than 90% of adults are infected with the virus in Thailand. It has been suggested that latent membrane protein 1 (LMP1) variants may differ in their tumorigenicity and geographical localization. The distribution of LMP1 variants of EBV in the Thai population was studied. A total of 259 LMP1 sequences from ten Thai ethnic groups (Lahu, Lisu, Shan, Red Karen, White Karen, Hmong, Akha, Mlabri, Moken and Urak Lawoi) were studied using direct PCR sequencing. Nucleotide sequences corresponding to the C terminus of the LMP1, including previously published sequences from central and southern Thais, were used in the phylogenetic analysis. Five strains - the B95-8 prototype, China 1, China 2, Mediterranean (Med) and SEA 2 - were identified in ethnic groups in Thailand. The major strain and the distribution pattern differed by group and location. When the ethnic groups were classified by linguistic group, the prevalence of the SEA 2 strain was significantly different between Austro-

Thais and other linguistic groups ($P=0.0001$), whereas, among Tibeto-Burman linguistic groups, the prevalence of the Med strain was different between matrilineal and patrilineal groups ($P=0.0245$). The distribution of LMP1 strains in ethnic minorities in Thailand is associated with ethnogeographical factors and the social/marriage system. This study thus provides evidence for the importance of interactions between populations in virus diversity.

Cysticercosis, a Potential Public Health Concern in Kuwait:
A New Diagnostic Method to Screen Taenia solium Taeniasis Carriers
in the Expatriate Population MEDICAL PRINCIPLES AND PRACTICE

English Article

Anti-T; solium taeniasis-specific IgG; ELISA; Taenia solium taeniasis; rES33 antigen PREVALENCE; ANTIGENS; EASTERN; ASSAY Objective: Taenia solium infection is not endemic to Kuwait, but several cases of cysticercosis have been detected in Kuwaiti nationals with no history of travelling to endemic countries. Infected domestic helpers/food handlers from endemic countries who may have escaped detection of infection by microscopy at the time of their arrival in Kuwait have been suspected as the possible source of infection. This study determined the seroprevalence of T. solium among domestic helpers/food handlers by screening their

blood using a sensitive taeniasis-specific anti-rES33 antibody assay. Subjects and Methods: Newly arrived domestic helpers (n = 500) and food handlers (n = 500) from endemic countries were enrolled in the period 2015–2017. *T. solium*-specific rES33 antigen was expressed and purified from human embryonic kidney (HEK)293-6E cells using the pTT5 mammalian expression vector. Stool samples were processed for microscopy, and blood samples were screened to detect anti-*T. solium*taeniasis-specific IgG antibodies by ELISA. Results: All stool samples were negative for *T. solium*parasiteeggs by microscopy. However, 42 individuals (4.2%) tested positive for *T. solium*taeniasis-specific IgG antibodies. Though statistically not significant, the IgG seropositivity was higher in individuals with a lower education level, a low-income background, and a lower frequency of hand-washing. Conclusions: This is the first report from Kuwait and the Middle East on the detection of anti-*T. solium*taeniasis-specific serum IgG antibodies among the high-risk expatriate population. The results emphasize the importance of efficient and sensitive screening of *T. solium* carriers and thus the prevention of infection transmission and development of cysticercosis in the local population. J Leone, A; Lecci, RM; Durante, M; Piraino, S Leone, Antonella; Lecci, Raffaella; Durante, Miriana; Piraino, Stefano Extract from the Zooxanthellate Jellyfish *Cotylorhiza tuberculata* Modulates Gap Junction Intercellular Communication in Human Cell Cultures MARINE DRUGS English Article

bioactive compounds; jellyfish extracts; zooxanthellae; gap junction intercellular communications; anticancer and antioxidant activity MARINE NATURAL-PRODUCTS; PERFORMANCE LIQUID-CHROMATOGRAPHY; POLYUNSATURATED FATTY-ACIDS; PELAGIA-NOCTILUCA CNIDARIA; STAPHYLOCOCCUS-AUREUS MRSA; CANCER CHEMOPREVENTION; RHOPILEMA-ESCULENTUM; PROTEIN-PURIFICATION; BIOACTIVE PEPTIDES; HEMOLYTIC-ACTIVITY On a global scale, jellyfish populations in coastal marine ecosystems exhibit increasing trends of abundance. High-density outbreaks may directly or indirectly affect human economical and recreational activities, as well as public health. As the interest in biology of marine jellyfish grows, a number of jellyfish metabolites with healthy potential, such as anticancer

or antioxidant activities, is increasingly reported. In this study, the Mediterranean "fried egg jellyfish" *Cotylorhiza tuberculata* (Macri, 1778) has been targeted in the search for putative valuable bioactive compounds. A medusa extract was obtained, fractionated, characterized by HPLC, GC-MS and SDS-PAGE and assayed for its biological activity on breast cancer cells (MCF-7) and human epidermal keratinocytes (HEKa). The composition of the jellyfish extract included photosynthetic pigments, valuable omega-3 and omega-6 fatty acids, and polypeptides derived either from jellyfish tissues and their algal symbionts. Extract fractions showed antioxidant activity and the ability to affect cell viability and intercellular communication mediated by gap junctions (GJIC) differentially in MCF-7 and HEKa cells. A significantly higher cytotoxicity and GJIC enhancement in MCF-7 compared to HEKa cells was recorded. A putative action mechanism for the anticancer bioactivity through the modulation of GJIC has been hypothesized and its nutraceutical and pharmaceutical potential was discussed. Kinetic Characteristics of Malic Enzyme in Human Breast Tissue
Cancer Cell Lines MCF-7 and MDA-MB-231 MIDDLE EAST JOURNAL OF
CANCER English Article

Malic enzyme; Breast cancer; Kinetics; Cancer
metabolism PURIFICATION; GLUTAMINASE; METABOLISM; PATHWAYS;
PROGRAM; LACTATE; GROWTH Background: A high level of
replication is one of the main indicators of tumors. Tumor cells
have to manufacture and transport macromolecules into daughter
cells. One of the required enzymes is malic enzyme, which
generates the NADPH for fatty acid synthesis in order to make cell
membrane and pyruvate, and support the glycolysis pathway to
supply the energy demand. Due to the enormous proliferation of
cancer cells, it is likely that the activity of malic enzyme in
cancer cells is more than normal cells. The aim of this study is
to survey the kinetics of malic enzyme in tumor and normal breast
tissues. Methods: We obtained the tumor and normal breast tissue
specimens directly from the operating room. The assays were
performed with partially purified samples under optimum conditions
for the substrate and co-factor requirements. The velocity of the
enzyme or Michaelis-Menten constant, maximum velocity, and the
amount of inhibitor that reduced the enzyme activity by 50% were
obtained and calculated in all samples. Results: The Michaelis-
Menten constant for malate was lower in tumors compared to normal
samples. In contrast, the maximum velocity for malate in tumors
was higher than normal tissues, whereas the amount of inhibitor
that reduced the enzyme activity by 50% of guanidine hydrochloride
and sodium chloride were both higher in tumors than normal
tissues. Conclusion: The obtained results indicated that the malic
enzyme kinetics had different patterns in tumor tissues in
comparison with normal tissues. A higher affinity of malic enzyme
for pyruvate production in tumors supported high aerobic
glycolysis. Moreover, it could be an approach to connect
glutaminolysis to the glycolysis pathway. Malic enzyme could be a
target to inhibit the glycolysis and glutaminolysis pathways in
tumors. [Ansari, Mahshid Bagherzadeh; Shahriari, Ali] Shahid

TACC3 Inhibitor as a Novel Anticancer Drug Candidate MOLECULAR
CANCER THERAPEUTICS English Article

TARGET; CELLS; PROTEIN;

PHOSPHORYLATION; MECHANISMS; CHECKPOINT; CLATHRIN; INVASION;
INSIGHTS TACC3, a transforming acidic coiled-coil (TACC) family
member, is frequently upregulated in a broad spectrum of cancers,
including breast cancer. It plays critical roles in protecting
microtubule stability and centrosome integrity that is often
dysregulated in cancers; therefore, making TACC3 a highly
attractive therapeutic target. Here, we identified a new TACC3-
targeting chemotype, BO-264, through the screening of in-house
compound collection. Direct interaction between BO-264 and TACC3
was validated by using several biochemical methods, including drug
affinity responsive target stability, cellular thermal shift
assay, and isothermal titration calorimetry. BO-264 demonstrated
superior antiproliferative activity to the two currently reported
TACC3 inhibitors, especially in aggressive breast cancer subtypes,
basal and HER2+, via spindle assembly checkpoint-dependent mitotic
arrest, DNA damage, and apoptosis, while the cytotoxicity against
normal breast cells was negligible. Furthermore, BO-264
significantly decreased centrosomal TACC3 during both mitosis and
interphase. BO-264 displayed potent antiproliferative activity
(similar to 90% have less than 1 μ mol/L GI(50) value) in the
NCI-60 cell line panel comprising of nine different cancer
types. Noteworthy, BO-264 significantly inhibited the growth of
cells harboring FGFR3-TACC3 fusion, an oncogenic driver in diverse
malignancies. Importantly, its oral administration significantly
impaired tumor growth in immunocompromised and immunocompetent
breast and colon cancer mouse models, and increased survival
without any major toxicity. Finally, TACC3 expression has been
identified as strong independent prognostic factor in breast
cancer and strongly prognostic in several different cancers.
Overall, we identified a novel and highly potent TACC3 inhibitor
as a novel potential anticancer agent, inducing spindle
abnormalities and mitotic cell death. [Akbulut, Ozge; Saatci,

Preprocessing of Public RNA-Sequencing Datasets to Facilitate Downstream Analyses of Human Diseases DATA
English Article; Data Paper
transcriptomics; RNA-sequencing; autoimmune diseases; cancer; pathogens; bacteria; viruses; data preprocessing
TRANSCRIPTOMICS; WORKFLOW Publicly available RNA-sequencing (RNA-seq) data are a rich resource for elucidating the mechanisms of human disease; however, preprocessing these data requires considerable bioinformatic expertise and computational infrastructure. Analyzing multiple datasets with a consistent computational workflow increases the accuracy of downstream meta-analyses. This collection of datasets represents the human intracellular transcriptional response to disorders and diseases such as acute lymphoblastic leukemia (ALL), B-cell lymphomas, chronic obstructive pulmonary disease (COPD), colorectal cancer, lupus erythematosus; as well as infection with pathogens including Borrelia burgdorferi, hantavirus, influenza A virus, Middle East respiratory syndrome coronavirus (MERS-CoV), Streptococcus pneumoniae, respiratory syncytial virus (RSV), severe acute respiratory syndrome coronavirus (SARS-CoV), and severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). We calculated the statistically significant differentially expressed genes and Gene Ontology terms for all datasets. In addition, a subset of the datasets also includes results from splice variant analyses, intracellular signaling pathway enrichments as well as read mapping and quantification. All analyses were performed using

well-established algorithms and are provided to facilitate future data mining activities, wet lab studies, and to accelerate collaboration and discovery.

MDA-MB-435s; human breast carcinoma; metastasis; HSV1-tk; bioluminescence; whole-body autoradiography HUMAN PROSTATE-CANCER; IN-VIVO; ANIMAL-MODEL; THYMIDINE KINASE; REPORTER GENE; MURINE MODELS; CELL-LINES; MICE; BONE; BIODISTRIBUTION Molecular imaging of reporter gene expression provides a rapid, sensitive and non-invasive monitoring of tumor behaviors. In this study, we reported the establishment of a novel animal model for longitudinal examination of tumor growth kinetics and metastatic spreading in vivo. The highly metastatic human breast carcinoma MDA-MB-435s cell line was engineered to stably express herpes simplex virus type 1 thymidine kinase (HSV-1-tk) and luciferase (luc). Both (131)-FIAU and D-luciferin were used as reporter probes. For orthotopic tumor formation, MDA-MB-435s/tk-luc cells were implanted into the first nipple of 6-week-old female NOD/SCID mice. For metastatic study, cells were injected via the lateral tail vein. Mice-bearing MDA-MB-435s/tk-luc tumors were scanned for tumor growth and metastasis using Xenogen IVIS50 system. Gamma scintigraphy and whole-body autoradiography were also applied to confirm the tumor localization. The results of bioluminescence imaging as well as histopathological finding showed that tumors

could be detected in femur, spine, ovary, lungs, kidney, adrenal gland, lymph nodes and muscle at 16 weeks post i.v. injection, and correlated photons could be quantified. This MDA-MB-435s/tk-luc human breast carcinoma-bearing mouse model combined with multimodalities of molecular imaging may facilitate studies on the molecular mechanisms of cancer invasion and metastasis. Background Colorectal cancer is the second cause of death for tumour worldwide. Among the risk factors for this disease the dietary habits seem to have a pivotal role. An elevated intake of fats causes a high release in the gut lumen of bile acids that are positively correlated with colorectal cancer, since they act as detergents and proliferation promoters. Recently, it was evidenced that bile acids can also be able to induce DNA damage. Aim of the study In this study the genotoxicity of deoxycholic acid (DCA) and chenodeoxycholic acid CDCA) has been evaluated in human normal colonocytes derived from 60 colon biopsies and in tumour cells. The involvement of reactive oxygen species (ROS) and the oxidative DNA damage was assessed. In addition, the protective effect exerted by both two well-known antioxidants commonly present in the diet, beta-carotene and alpha-tocopherol, and butyrate which is known to be involved in the regulation of several cellular functions, has also been tested. Methods The DNA damage was evaluated by the "comet assay" or single cell gel electrophoresis (SCGE) both in its conventional use and by the Endonuclease III

modified method, which allow to detect the presence of oxidized pyrimidines. Results Bile acids (CDA and CDCA) resulted genotoxic on both normal and tumour human colon cells. The inclusion of the endonuclease III digestion step in the comet assay demonstrated that bile acids induced an oxidative DNA damage. In addition, treatment of colonocytes with bile acids in the presence of the antioxidants (beta-carotene, alpha-tocopherol) and Na-butyrate caused a reduction of DNA damage. Conclusion Our results suggest that bile acids may be involved in the tumour initiation by inducing a DNA oxidative damage, and so add further evidences to the preventive properties of antioxidants present in the Mediterranean diet. Female breast cancers are getting smaller, but socio-demographic differences remain AUSTRALIAN AND NEW ZEALAND JOURNAL OF PUBLIC HEALTH English Article

SOUTH-AUSTRALIA; CASE-SURVIVAL

Objective: To investigate trends towards early detection of infiltrating ductal carcinomas, possible effects on patients' prognosis, and characteristics of women still at high risk of late detection. Methods: South Australian Cancer Registry data were analysed to compare breast tumour diameters for the 1980-86 and 1997-2002 diagnostic periods by age. Relative survivals for 1980-86 were compared with corresponding survival estimates for 1997-2000, obtained by weighting diameter-specific survivals for 1980-86 to equate with the diameter distribution for 1997-2002.

Multivariable logistic regression was used to determine socio-demographic predictors of large diameters (greater than or equal to 30 mm) in 1997-2002. Results: The proportion of tumours with diameters smaller than 15 mm increased from 13.0% in 1980-86 to 36.7% in 1997-2002, whereas the proportion with large diameters reduced from 43.0% to 18.6%. Estimated changes in 20-year survivals equated with a 33% reduction in breast-cancer mortality among patients aged 50-69 years at diagnosis. Data for 1997-2002 indicate that early diagnosis is not evenly distributed, with large diameters more common in age ranges outside the 50-69 year target for mammography screening; low socio-economic areas; non-Caucasians; patients born in northern/eastern Europe and potentially Asia/Middle East; and in some country locations.

Conclusions and implications: Increased emphasis on early detection should be directed at sectors of the population where

delays in diagnosis and poorer prognosis are evident. Projected reductions in breast-cancer mortality among patients are indicative of effects of earlier detection on patients' prognosis, but require confirmation with follow-up data. More particularly, parallel studies of effects on population-based mortality are warranted. Decne inducing apoptotic cell death in human cancer cells:
Implication in chemopreventive mechanism EMIRATES JOURNAL OF
FOOD AND AGRICULTURE English Article

Cell biology; Cancer chemoprevention;
Anticancer drugs; Cell signaling; Natural compounds NF-KAPPA-B;
SIGNALING PATHWAYS; NATURAL-PRODUCTS; ANGIOGENESIS; DIETARY;
BREAST; GROWTH; INHIBITION; VEGF; PI3K/AKT/MTOR Cancer is
associated with a high rate of pre-mature mortality worldwide and
serves as a significant impediment to extended life expectancy,
leading to undesirable long-term effects on the quality of life of
the patients. Bioactive chemical products derived from natural
sources have an important place in the well-being of the human
population since ancient times. Compounds derived from natural
sources have dominated the drug discovery programs in the last
five decades and comprise a substantial proportion of current-day
pharmaceutical agents. *Rhazya stricta*, an evergreen shrub, it
belongs to family Apocynaceae of order Gentianales, and the *Rhazya*
stricta is known to have certain medicinal properties, as the
Middle East and South Asian traditional medicine employed this
plant as a cure for different diseases. Herein, the hydro-
methanolic extract of *Rhazya stricta* Decne has been studied for
its effect on spectrum of cancer cells, including LNCaP, C4-2B,
PC-3 prostate cancer cells, MDA-MB-231, MCF-7, SKBR3 breast cancer
cells, A-549 lung cancer cells and BxPC-3, MiaPaCa-2 pancreatic
cancer. Hydro-methanolic extract of *Rhazya stricta* Decne in a
dose-dependent manner, showed progressive inhibition of cell
growth by induction of cell death in the treated human cancer
cells. The IC50 value range for different breast cancer cell lines
was 142-178 μ g/ml; for prostate cancer cell lines, it was 90-
148 μ g/ml; for pancreatic cancer cell lines 116-166 μ g/ml
and for the lung cancer cells, it was reported to be 180 μ
 μ g/ml. The anti-metastatic potential of extract was indicated by
the notable reduction in invasiveness and cell migration.

Moreover, the structurally diverse phytochemical rich extract, also downregulates the signaling of NF-kB and the NF-kB downstream target cytokine VEGF, providing an insight into the anticancer action mechanism. North-south gradients in plasma concentrations of B-
vitamins and other components of one-carbon metabolism in Western
Europe: results from the European Prospective Investigation into
Cancer and Nutrition (EPIC) Study BRITISH JOURNAL OF NUTRITION

English Article

B-

vitamins; Amino acids; One-carbon metabolism; Europe

COLORECTAL-CANCER; MICROBIOLOGICAL ASSAY; ALCOHOL-

CONSUMPTION; TOTAL HOMOCYSTEINE; DIETARY PATTERNS; NUTRIENT INTAKE; DAIRY-PRODUCTS; FOLATE INTAKE; 10 COUNTRIES; ELDERLY-MEN

Different lifestyle patterns across Europe may influence plasma concentrations of B-vitamins and one-carbon metabolites and their relation to chronic disease. Comparison of published data on one-carbon metabolites in Western European regions is difficult due to differences in sampling procedures and analytical methods between studies. The present study aimed, to compare plasma concentrations of one-carbon metabolites in Western European regions with one laboratory performing all biochemical analyses. We performed the present study in the European Prospective Investigation into Cancer and Nutrition (EPIC) cohort among 5446 presumptively healthy individuals. Quantile regression was used to compare sex-specific median concentrations between Northern (Denmark and Sweden), Central (France, Germany, The Netherlands and United Kingdom) and Southern (Greece, Spain and Italy) European regions. The lowest folate concentrations were observed in Northern Europe (men, 10.4 nmol/l; women, 10.7 nmol/l) and highest concentrations in Central Europe. Cobalamin concentrations were slightly higher in Northern Europe (men, 330 pmol/l; women, 352 pmol/l) compared with Central and Southern Europe, but did not show a clear north-south gradient. Vitamin B-2 concentrations were highest in Northern Europe (men, 22.2 nmol/l; women, 26.0 nmol/l) and decreased towards Southern Europe (P -trend < 0.001). Vitamin B-6 concentrations were highest in Central Europe in men (77.3 nmol/l) and highest in the North among women (70.4 nmol/l), with decreasing concentrations towards Southern Europe in women (P -trend < 0.001). In men, concentrations of serine, glycine and sarcosine increased from the north to south. In women, sarcosine increased from Northern to Southern Europe. These findings may provide relevant information for the study of regional differences of chronic disease incidence in association with lifestyle.

Age at diagnosis for lung, colon, breast and prostate
 cancers: An international comparative study INTERNATIONAL JOURNAL
 OF CANCER English Article

age at cancer diagnosis; cancer epidemiology;
 international comparison 187 COUNTRIES; PREVALENCE; ANCESTRY;
 BIOLOGY; WOMEN; MEN Differences in the average age at cancer
 diagnosis are observed across countries. We therefore aimed to
 assess international variation in the median age at diagnosis of
 common cancers worldwide, after adjusting for differences in
 population age structure. We used IARC's Cancer Incidence in Five
 Continents (CI5) Volume XI database, comprising cancer diagnoses
 between 2008 and 2012 from population-based cancer registries in
 65 countries. We calculated crude median ages at diagnosis for
 lung, colon, breast and prostate cancers in each country, then
 adjusted for population age differences using indirect
 standardization. We showed that median ages at diagnosis changed

by up to 10 years after standardization, typically increasing in low- and middle-income countries (LMICs) and decreasing in high-income countries (HICs), given relatively younger and older populations, respectively. After standardization, the range of ages at diagnosis was 12 years for lung cancer (median age 61-Bulgaria vs 73-Bahrain), 12 years for colon cancer (60-the Islamic Republic of Iran vs 72-Peru), 10 years for female breast cancer (49-Algeria, the Islamic Republic of Iran, Republic of Korea vs 59-USA and others) and 10 years for prostate cancer (65-USA, Lithuania vs 75-Philippines). Compared to HICs, populations in LMICs were diagnosed with colon cancer at younger ages but with prostate cancer at older ages (both pLMICS-vs-HICs < 0.001). In countries with higher smoking prevalence, lung cancers were diagnosed at younger ages in both women and men (both p(corr) < 0.001). Female breast cancer tended to be diagnosed at younger ages in East Asia, the Middle East and Africa. Our findings suggest that the differences in median ages at cancer diagnosis worldwide likely reflect population-level variation in risk factors and cancer control measures, including screening.

Acceptability of the human papilloma virus vaccine
among Moroccan parents: a population-based cross-sectional study
EASTERN MEDITERRANEAN HEALTH JOURNAL English
Article CERVICAL-
CANCER; HPV VACCINE; PARTICLE VACCINE; YOUNG-WOMEN; ATTITUDES;
ACCEPTANCE; INFECTION; KNOWLEDGE; EFFICACY; PREDICTORS Data
about the public's awareness and acceptability of the human
papilloma virus (HPV) vaccine are lacking in the Eastern
Mediterranean Region. This study aimed to explore parental
acceptability of HPV vaccination for their daughters in Morocco. A
cross-sectional survey was carried out among mothers and fathers
of girls aged 12-15 years at 12 middle schools from 6 regions of
Morocco. Despite weak knowledge of genital warts and HPV
infection, acceptability of the HPV vaccine was 76.8% (95% CI:
73.3-79.9%) among mothers and 68.9% (95% CI: 65.2-72.5%) among
fathers. Only 8.8% of mothers and 7.0% of fathers were against
administration of the HPV vaccine to their daughters. Predictors
of parents' acceptance of the HPV vaccine were living in
precarious housing/slums and low household income (for mothers)
and living in urban areas (for fathers). These results will be
useful for preparing the introduction of the HPV vaccine in health
ministry programmes. [Selmouni, F.] Univ Complutense Madrid,

Metallic trace element dynamics in *Paracentrotus lividus* from Algeria: Environmental and human health risk
assessment MARINE POLLUTION BULLETIN English
Article Metallic trace
elements; *Paracentrotus lividus*; Health risk assessment;
Environmental monitoring; Mediterranean Sea; Atlantic MUSSELS
MYTILUS-GALLOPROVINCIALIS; SOUTHERN ADRIATIC SEA; HEAVY-METALS;
REPRODUCTIVE-CYCLE; POSIDONIA-OCEANICA; HUMAN EXPOSURE;
MEDITERRANEAN SEA; CADMIUM EXPOSURE; BREAST-CANCER; URCHIN This
paper evaluates the dynamic of metallic trace elements (MTEs; Cd,
Pb, Fe, Cu, Zn, Ni and Co) in the sea urchin *Paracentrotus lividus*
collected in five sites: four contaminated and one reference,
along the western coast of Algeria, recontextualizes this
contamination within a wider geographical distribution area
throughout 84 sites among the Mediterranean Sea and Atlantic and
focuses on the potential risk on human health for the first time
in Algeria. The Trace Element Pollution Index places Algeria, and
generally the North African coasts, as the region most
contaminated by MTEs. The Trace Element Spatial Variation Index
ranks Pb as an MTE of key environmental concern according to
global spatial variability. The health risk assessment indicates
that Cd and Pb, exceed the maximum limits set by the Commission
Regulation (EC) No 1881/2006 on three of the four contaminated
sites. [Bouiba, Samira; Bendimerad, Mohammed El Amine] Abou

Incidence of Schizophrenia Among Second-Generation

immigration; risk; Israel; birth cohort; longitudinal
PSYCHOTIC DISORDERS; ETHNIC-MINORITIES; INCREASED RATES;
RISK-FACTOR; VITAMIN-D; DISCRIMINATION; SURINAMESE; MIGRATION;
AFRICAN; NETHERLANDS Objective: Increased incidence of
schizophrenia is observed among some immigrant groups in Europe,
with the offspring of immigrants, ie "second-generation"
immigrants particularly vulnerable. Few contemporary studies have
evaluated the risk of schizophrenia among second-generation
immigrants in other parts of the world. Methods: We studied the
incidence of schizophrenia in relation to parental immigrant
status in a population-based cohort of 88 829 offspring born in
Jerusalem in 1964-1976. Parental countries of birth were obtained
from birth certificates and grouped together as (1) Israel, (2)
Other West Asia, (3) North Africa, and (4) Europe and
industrialized countries. Cox proportional hazards methods were
used in adjusting for sex, parents' ages, maternal education,
social class, and birth order. Results: Linkage with Israel's
Psychiatric Registry identified 637 people admitted to psychiatric
care facilities with schizophrenia-related diagnoses, before 1998.
Incidence of schizophrenia was not increased among second-
generation immigrants in this birth cohort, neither overall nor by
specific group. Conclusions: The difference in risk of
schizophrenia among second-generation immigrants in Europe and in
this Israeli birth cohort suggests that the nature of the
immigration experience may be relevant to risk, including reasons
for migration, the nature of entry, and subsequent position in the
host country for immigrants and their offspring. Minority status
may be of importance as, in later studies, immigrants to Israel
from Ethiopia had increased risk of schizophrenia. [Corcoran,

Ming-Chih Erianin induces cell apoptosis through ERK
pathway in human nasopharyngeal carcinoma BIOMEDICINE &
PHARMACOTHERAPY English Article

Erianin; Nasopharyngeal cancer; Apoptosis; ERK
DEATH; AUTOPHAGY Background: Nasopharyngeal carcinoma (NPC)
is one of the most common cancers in areas of Southeast Asia, such
as Taiwan, and North Africa. The treatments of NPC, including
radiotherapy and chemotherapy, were effective, but they also
caused some severe side effects. Erianin, a natural product
derived from Dendrobium, was proved to have anti-cancer effect in
hepatoma, melanoma, non-small-cell lung carcinoma, myelogenous
leukemia, breast cancer, and osteosarcoma. Hypothesis/Purpose:
According to previous research, we hypothesized that erianin
inhibits cancer cell growth through apoptotic mechanisms. This
study aimed to determine whether Erianin has an anti-NPC effect
and what mechanisms were involved. Methods and Results: The result
showed that erianin significantly increased activation of
apoptosis in NPC cell lines (NPC-039 and NPC-BM) and arrest the
cell cycle obviously through mitochondrial membrane alternation,
death receptors activation, and caspase-3, -8, -9 activation.
Phosphorylated ERK1/2 was also decreased in erianin-treated NPC
cell with dose-dependent manner, and the result was thought to
promote apoptosis. Furthermore, the increased rate of apoptotic
cells with erianin plus it's inhibitors (U) was also revealed in
this study. Conclusion: In conclusion, this is the first research
to identify the anti-NPC effect of erianin via the apoptosis
mechanism. Erianin was a promising natural agent against
nasopharyngeal carcinoma. [Liu, Yen-Tze; Hsieh, Ming-Ju; Chou,

J Bogusz, A; Gornicka, M Bogusz, Angelika; Gornicka, Magdalena Low Diet Quality and Nutritional Knowledge in Women with Endometriosis: A Pilot Study HEALTHCARE English Article

endometriosis; healthy diet; Mediterranean diet; nutritional knowledge; Polish women BREAST-CANCER; RISK; INFLAMMATION; MANAGEMENT Endometriosis is a chronic gynecological disease characterized by ectopic endometrial tissue outside the uterus that can cause chronic pain, dysmenorrhea, fatigue, and infertility. The aim of this study was to assess diet quality and nutritional knowledge of women with endometriosis. A questionnaire was used to collect data on lifestyle, dietary habits and nutritional knowledge from 90 women. More than 80% of women with endometriosis (82.2%) confirmed that diet and lifestyle are related to the progression of endometriosis. After being diagnosed with endometriosis, 77.3% of respondents reported a change in their dietary habits and made various changes to their diet by increasing or eliminating the consumption of certain foods. The majority declared reducing pro-inflammatory products, increasing anti-inflammatory foods, including the consumption of vegetables and fruits, avoiding white/or red/or processed meat, and avoiding sweets. Nevertheless, diet quality as assessed by the pro-healthy diet index (pHDI-10) and the Mediterranean Diet Score (MDS) showed a low intensity of consumption of pro-healthy food (average pHDI-10 value 31.4%; MDS 7.55/14 points, $p = 0.0001$). Women with endometriosis reported lower than recommended consumption of fruits, vegetables, dairy products and whole grains. A higher percentage of healthy controls had a "good" level of nutritional knowledge than women with endometriosis. The results of our study highlight the need to improve diet quality

and nutritional knowledge among women with endometriosis as well as developing targeted dietary recommendations to help improve well-being and reduce the pain symptoms of endometriosis.

LIFE-BASEL English Article

Olea europaea L.; Mediterranean diet;

hydroxytyrosol; oleuropein; chronic degenerative non-communicable

diseases; HEK-293E; chronic kidney disease; IncuCyte VIRGIN

OLIVE OIL; MEDITERRANEAN DIET; COLORECTAL-CANCER; OLEUROPEIN;

INHIBITION; EXPRESSION; PHENOLICS Background: Extra virgin olive

oil is a typical food of the Mediterranean area, obtained by

pressing *Olea europaea* L. fruits. Its polyphenols have been

studied for their antioxidant function and protective action

against cancer and chronic kidney disease. In this in vitro study,

we tested titrated extracts from *Olea europaea* L. on a human

embryonic kidney 293 (HEK-293E) cell line, regarding their pro-

apoptotic and antiproliferative capacities, using " IncuCyte (R)

S3 Live-Cell Analysis System". Materials and Methods: We selected

Olea europaea L. active compounds like hydroxytyrosol (HT) and

oleuropein (OLE). These extracts were tested at different

concentrations and characterized by HPLC-DAD-MS for the content in

secondary active metabolites. The real-time observation of cell

behavior was performed by IncuCyte, which can quantitatively

analyze the cell proliferation and death. Results: This study

showed that all the tested extracts can significantly inhibit

cellular growth at 50 μ M but the reduced proliferation is not

related to an increase in cellular apoptosis. Instead, the same

analysis performed by using extracts at 100 μ M reveals that they

can inhibit cellular growth, further inducing cellular apoptosis.

Conclusions: The results on the HEK-293E cells confirmed the

antiproliferative and proapoptotic actions of active compounds

from an *Olea europaea* L. matrix in this cell line. [Marrone,

Dietary Patterns and Plasma Sex Hormones, Prolactin, and Sex Hormone-Binding Globulin in Premenopausal Women CANCER
EPIDEMIOLOGY BIOMARKERS & PREVENTION English

Article BREAST-CANCER

RISK; SERUM ESTROGEN-LEVELS; FOOD FREQUENCY QUESTIONNAIRE; CORONARY-HEART-DISEASE; HEALTHY EATING INDEX; POSTMENOPAUSAL WOMEN; ALCOHOL-CONSUMPTION; MEDITERRANEAN DIET; REGRESSION-MODELS; STEROID-HORMONES Background: Sex hormones are important for breast cancer, but it is unclear whether dietary patterns influence hormone concentrations. Methods: Dietary pattern adherence scores for the alternate Mediterranean diet (aMED), Dietary Approaches to Stop Hypertension (DASH), and Alternative Healthy Eating Index (AHEI) were calculated from semiquantitative food frequency questionnaires administered in 1995 and 1999. Premenopausal plasma

concentrations of sex hormones were measured in samples collected in 1996 to 1999. We used generalized linear models to calculate geometric mean hormone concentrations across quartiles of dietary pattern scores among 1,990 women in the Nurses' Health Study II. Results: We did not observe significant associations between sex hormone concentrations and the DASH pattern and only one suggestive association between follicular estrone concentrations and the aMED pattern [top vs. bottom quartile -4.4%, 95% confidence interval (CI), -10.6% to 2.1%; P-trend = 0.06]. However, women in the top versus bottom quartile of AHEI score had lower concentrations of follicular (-9.1%; 95% CI, -16.1% to -1.4%; P-trend = 0.04) and luteal (-7.5%; 95% CI, -13.6% to -0.9%; P-trend = 0.01) estrone, luteal-free (-9.3%; 95% CI, -16.8% to -1.1%; P-trend = 0.01) and total (-6.7 %; 95% CI, -14.3% to 1.5%; P-trend = 0.04) estradiol, follicular estradiol (-14.2%; 95% CI, -24.6% to -2.4%; P-trend = 0.05), and androstenedione (-7.8%; 95% CI, -15.4% to 0.4%; P-trend = 0.03). Conclusion: Diet quality measured by the AHEI is inversely associated with premenopausal estrogen concentrations. Given that we did not observe similar associations with the aMED or DASH patterns, our findings should be interpreted with caution. Impact: Given the role of estrogens in breast cancer etiology, our findings add to the substantial evidence on the benefits of adhering to a healthy diet. (C) 2016 AACR. Chemoprevention of Intestinal Polyps in

Apc^{Min/+} Mice Fed with Western or Balanced Diets by Drinking Annurca Apple Polyphenol Extract CANCER PREVENTION RESEARCH English Article

MEDITERRANEAN DIET; COLORECTAL-CANCER; DNA METHYLATION; GROWTH-FACTOR; PREVENTION; CYCLOOXYGENASE-2; (-)-EPIGALLOCATECHIN-3-GALLATE; EXPRESSION; CELECOXIB; EFFICACY The Western diet (WD) is associated with a higher incidence of colorectal cancer (CRC) than the Mediterranean diet. Polyphenols extracted from Annurca apple showed chemopreventive properties in CRC cells. A multifactorial, four-arm study by using wild-type (wt) and Apc(Min/+) mice was carried out to evaluate the effect on polyp number and growth of APE treatment (60 μ mol/L) ad libitum in drinking water combined with a WD or a balanced diet (BD) for 12 weeks. Compared with APE treatment, we found a significant drop in body weight ($P < 0.0001$), severe rectal bleeding ($P = 0.0076$), presence of extra-intestinal tumors, and poorer activity status ($P = 0.0034$) in water-drinking Apc(Min/+) mice, more remarkably in the WD arm. In the BD and WD groups, APE reduced polyp number (35% and 42%, respectively, $P < 0.001$) and growth (60% and 52%, respectively, $P < 0.0001$) in both colon and small intestine. Increased antioxidant activity was found in wt animals fed both diets and in Apc(Min/+) mice fed WD and drinking APE. Reduced lipid peroxidation was found in Apc(Min/+) mice drinking APE fed both diets and in wt mice fed WD. In normal mucosa, mice drinking water had lower global levels of DNA methylation than mice drinking APE. APE treatment is highly effective in reducing polyps in Apc(Min/+) mice and supports the concept that a mixture of phytochemicals, as they are naturally present in foods, represent a plausible chemopreventive agent for CRC, particularly in populations at high risk for colorectal neoplasia. AMERICAN JOURNAL OF CLINICAL NUTRITION English
Article aHEI; alternate

Mediterranean diet; cardiometabolic biomarkers; DASH; dietary patterns HYPERTENSION DASH DIET; CORONARY-HEART-DISEASE;

CARDIOVASCULAR-DISEASE; MEDITERRANEAN DIET; INSULIN-RESISTANCE;
ADIPONECTIN LEVELS; BREAST-CANCER; C-PEPTIDE; RISK; QUALITY

Background: Healthful dietary patterns have been associated with lower risks of type 2 diabetes and coronary artery disease, but their relations with intermediate markers of cardiometabolic and endocrine health are less established. Objective: We evaluated the Dietary Approaches to Stop Hypertension (DASH), the alternate Mediterranean diet (aMED), and the Alternate Healthy Eating Index (aHEI) diet-quality scores with cardiometabolic and endocrine plasma biomarkers in US women. Design: The trial was a cross-sectional analysis of 775 healthy women in the Women's Lifestyle Validation Study that was conducted within the NHS (Nurses' Health Study) and NHS II longitudinal cohorts. Multiple linear regression models adjusted for potential confounders were used to estimate associations between quartiles of dietary pattern-adherence scores that were derived from a food-frequency questionnaire and plasma biomarker concentrations that were collected simultaneously.

Results: In multivariable models in which highest and lowest quartiles of dietary pattern scores were compared, 1) DASH was significantly associated with higher concentrations of high-density lipoprotein (9%) and sex-hormone binding globulin (SHBG) (21%), and lower concentrations of leptin (28%), triglycerides (19%), and C-peptide (4%) (all P-trend ≤ 0.04); 2) the aMED was associated with 19% higher SHBG and 16% lower triglycerides (P-trend = 0.02 and 0.003, respectively); and 3) the aHEI was associated with significantly higher concentrations of insulin (16%) and SHBG (19%) and lower concentrations of leptin (18%) (all P-trend ≤ 0.02). Further adjustment for body mass index (BMI) attenuated these associations but remained significant for 1) DASH with leptin and triglycerides and 2) the aMED with triglycerides (all P-trend ≤ 0.03). Conclusions: Adherence to healthful dietary patterns is associated with favorable concentrations of many cardiometabolic and endocrine biomarkers. These relations are mediated in part by BMI. MEDICAL HYPOTHESES English Article
HUMAN-PAPILLOMAVIRUS; NARGHILE

SMOKING; TOBACCO SMOKING; LUNG-CANCER; HEAD; ASSOCIATION; RISK

While cigarette smoking is recognized as an important risk factor in human oral cancers, the effect of water pipe smoking (WPS) on these cancers is not known. WPS is very common in the young adult population, especially in the Middle East, and has been associated with several respiratory problems. However, to date, there have been no studies examining the association between WPS and the progression of human oral cancers. Currently, the role of WPS in human oral cancers remains uncertain because of the limited number of investigations. This raises the question of whether WPS plays a significant role in the development of human oral carcinomas. In this paper, we propose the hypothesis that human oral normal epithelial cells are vulnerable to persistent WPS; moreover, WPS could play an important role in the initiation of a neoplastic transformation of human normal oral epithelial cells. Therefore, we believe that an international collaboration of epidemiological and clinical studies as well as cellular and molecular biology investigations is necessary to answer this important question. Image Classification via Computer-Aided Pathology: An Available
Dataset for Imaging AnalysisANIMALS English

Article breast cancer; canine
mammary tumor (CMTs); CMT dataset; deep learning; machine
learning; histological classification DIGITAL PATHOLOGY; CANCER;
MODEL; DIAGNOSIS; NETWORKS; FUSION Digital pathology (DP) and
computer-aided diagnosis (CAD) are rapidly evolving fields that
have great potential for improving the accuracy and efficiency of
cancer diagnosis, including that of canine mammary tumors (CMTs),
the most common neoplasm in female dogs. The work presents a study
on the development of CAD systems for the automated classification
of CMTs utilizing convolutional neural networks (CNNs) to extract
features from histopathological images of CMTs and classify them
into benign or malignant tumors. The study shows that the proposed
framework can accurately distinguish between benign and malignant
CMTs, with testing accuracies ranging from 0.63 to 0.85. The study
emphasizes how digital pathology and CAD could help veterinarians
and pathologists in accurately diagnosing the tumor type, which is
crucial in determining the optimal course of treatment. Overall,
digital pathology and CAD are promising tools that could improve
the accuracy and efficiency of cancer diagnosis, including that of
canine mammary tumors. Histopathology, the gold-standard technique
in classifying canine mammary tumors (CMTs), is a time-consuming
process, affected by high inter-observer variability. Digital (DP)
and Computer-aided pathology (CAD) are emergent fields that will
improve overall classification accuracy. In this study, the
ability of the CAD systems to distinguish benign from malignant
CMTs has been explored on a dataset-namely CMTD-of 1056
hematoxylin and eosin JPEG images from 20 benign and 24 malignant
CMTs, with three different CAD systems based on the combination of
a convolutional neural network (VGG16, Inception v3,
EfficientNet), which acts as a feature extractor, and a classifier
(support vector machines (SVM) or stochastic gradient boosting

(SGB)), placed on top of the neural net. Based on a human breast cancer dataset (i.e., BreakHis) (accuracy from 0.86 to 0.91), our models were applied to the CMT dataset, showing accuracy from 0.63 to 0.85 across all architectures. The EfficientNet framework coupled with SVM resulted in the best performances with an accuracy from 0.82 to 0.85. The encouraging results obtained by the use of DP and CAD systems in CMTs provide an interesting perspective on the integration of artificial intelligence and machine learning technologies in cancer-related research.

J Nasserri, K; Mills, PK; Allan, M Nasserri, Kiumarss; Mills, Paul K.; Allan, Mark Cancer incidence in the Middle Eastern population of California, 1988-2004 ASIAN PACIFIC JOURNAL OF CANCER PREVENTION English Article Middle Eastern immigrants; cancer incidence; California; ethnic studies THYROID-CANCER; UNITED-STATES; MIGRANTS; RISKS; IMMIGRANTS; REGISTRY; SWEDEN; NAMES International statistics suggest lower cancer incidence in the Middle East and Middle Eastern (ME) immigrants in Europe, Australia, and Canada, but little is known from the United States. This study compares cancer rates in ME population with other race/ethnic groups in California from 1988 through 2004. ME cases in California cancer registry were identified by surname and ME population was estimated from U.S. Census data. Cancer rates for ME countries was obtained from Globocan. The ME incidence rate ratios for all sites combined in male and female were 0.37 and 0.82, respectively and were statistically significant. ME rates were significantly lower for cancers of the colon, lung, skin melanoma, female breast and prostate, and were significantly higher for cancers of the

stomach, liver, thyroid, leukemia, and male breast. Cancer incidence in ME population in California was 2.4 times higher than rates in home countries. Incidence trends in ME males remained fairly stable but in females shows a slight decline in recent years. Cancer incidence in ME population is lower than non-Hispanic white and non-Hispanic Black, but is higher than rates for Hispanics and Asians, and ME countries. Improved data quality, chronic infections, acculturation, and access to screening services are some of the factors responsible for the observed patterns.

Obesity, Insulin Resistance, and Hyperandrogenism Mediate the Link between Poor Diet Quality and Ovarian Dymorphology in Reproductive-Aged Women NUTRIENTS English

Article Mediterranean Diet; Dietary Approaches to Stop Hypertension; ovary; fertility; metabolism ANTRAL FOLLICLE COUNTS; HIGH-FAT DIET; NEGATIVE BREAST-CANCER; POLYCYSTIC-OVARY; MEDITERRANEAN DIET; VITAMIN-D; STYLE DIET; MENSTRUAL-CYCLE; GLYCEMIC INDEX; WEIGHT-GAIN The relationship between diet quality and ovarian morphology has biological plausibility yet remains unclear and was therefore evaluated. In a multicenter cross-sectional analysis, four dietary patterns were scored for 111 consecutive reproductive-aged women (18-45 years) using (1) Healthy Eating Index (HEI-2015); (2) alternative HEI-2010; (3) alternate Mediterranean Diet (aMED); (4) and Dietary Approaches to Stop Hypertension (DASH) indices. Ovarian volume (OV) and follicle number per ovary (FNPO) were evaluated on transvaginal ultrasonography. Relationships between dietary and ovarian morphology indices were evaluated by linear regression and mediation analyses. Associations between aMED and DASH scores and OV/FNPO were completely mediated by obesity, insulin resistance, and hyperandrogenism (All:p< 0.05), unlike direct associations (All:p >= 0.89). Namely, a 1-standard deviation [SD] increase in aMED score was associated with decreases in OV (0.09 SD; 0.4 mL) through reducing waist circumference. Likewise, a 1 SD increase in aMED and DASH score was associated with decreases in OV (0.07 SD; 0.3 mL) by reducing glucose response to a 75 g glucose tolerance test. A 1 SD increase in DASH score was associated with decreased FNPO (0.07 SD; 2 follicles) by reducing free androgen index (All:p< 0.05). Adherence to aMED and DASH eating plans was indirectly associated with significant improvements in ovarian form, providing novel mechanistic insights for future interventions about contributions of diet quality on ovarian function.  Cancer control capacity in 50 low- and middle-income
 countries GLOBAL PUBLIC HEALTH English Article
 World Health Organization;
 International Atomic Energy Agency; cancer control; National
 Cancer Control Programme; Plan; low- and middle-income countries
 HEALTH; AFRICA Within the World Health Organization-
 International Atomic Energy Agency (WHO-IAEA) collaboration for
 delivery of technical assistance to its Member States, the

National Cancer Control Programme/Plan (NCCP) Core Capacity Self-Assessment Tool has been used to obtain a simple and quick qualitative overview of national cancer control planning and on-going activities. The NCCP tool was applied in 50 Member States, which were classified as low- and middle-income countries in 2012. Results show that half of these countries reported having officially endorsed an NCCP and 42% were in the process of preparing or updating one. Overall, the most relevant cancer control interventions reported to be partially developed or well established in most countries were related to the cancer prevention, early detection of cervical and breast cancers, as well as diagnosis and treatment of curable cancers. Contrarily, patient's rehabilitation, psychosocial support, human papilloma virus vaccination, breast cancer screening with mammography and control of occupational carcinogens were noted as being in early development phases. The availability of crucial resources to support interventions was perceived to be the highest in upper middle-income countries. These findings highlight specific areas where WHO, IAEA and partners could strengthen collaboration with countries to leverage on-going interventions and improve availability of resources. Prevalence and Socioeconomic Correlates of Adult Obesity in
Europe: The Feel4Diabetes Study INTERNATIONAL JOURNAL OF
ENVIRONMENTAL RESEARCH AND PUBLIC HEALTH English

Article obesity; education;
income security; occupation; socioeconomic factors WEIGHT-GAIN;
UNEMPLOYMENT; INSECURITY; HEALTH; FOOD To effectively tackle
obesity, it is necessary to identify all specific socioeconomic
factors which contribute to its development. We aimed to highlight
the prevalence of adult overweight/obesity in European countries
and investigate the association of various socioeconomic factors
and their accumulative effect on overweight/obesity status. Cross-
sectional data from the Feel4Diabetes study for 24,562 adults
residing in low socioeconomic areas were collected, representing
Belgium, Finland, Greece, Spain, Bulgaria, and Hungary.
Socioeconomic Burden Score (SEBS) was created, accounting for
unemployment, financial insecurity, and education ≤ 12 years.
Data were analyzed using analysis of variance and logistic
regression. In total, 19,063 adults with complete data were
included (34.5% overweight and 15.8% obese). The highest
overweight/obesity rates occurred in Greece (37.5%/17.8%) and
Hungary (35.4%/19.7%). After adjusting for confounders, age of <45
years and female sex were inversely associated with
overweight/obesity, while low educational level (≤ 12 years),
unemployment, and financial insecurity were positively associated.
The increase in SEBS (clustering of socioeconomic disadvantages)
was associated with increased overweight/obesity likelihood. This
association of SEBS scores with overweight/obesity was evident for
males and females across all examined countries, excluding males
in low-income countries (Bulgaria and Hungary), where the highest
SEBS score was inversely associated with overweight/obesity. The
clustering burden of socioeconomic disadvantages on
overweight/obesity was found to be influenced by the countries'
economic state and sex.

J Daniels, B; Chang, AY; Gatti, R; Das, J Daniels, Benjamin; Chang, Andres Yi; Gatti, Roberta; Das, Jishnu The medical competence of health care providers in sub-Saharan Africa: Evidence from 16 127 providers across 11 countries HEALTH AFFAIRS SCHOLAR English Article health care providers; quality of care; medical vignettes; sub-Saharan Africa; health systems; service delivery indicators; SDI QUALITY; VIGNETTES Despite a consensus that quality of care is critically deficient in low-income countries, few nationally representative studies provide comparable measures of quality of care across countries. To address this gap, we used nationally representative data from in-person administrations of clinical vignettes to measure the competence of 16 127 health care providers across 11 sub-Saharan African countries. Rather than large variations across countries, we found that 81% of the variation in competence is within countries and the characteristics of health care providers do not explain most of this variation. Professional qualifications-including cadre and education-are only weakly associated with competence: across our sample, one-third of nurses are more competent than the average doctor in the same country and one-quarter of doctors are less competent than the average nurse. Finally, while younger cohorts do tend to be more competent, perhaps reflecting improvements in medical education, it would take 25 decades of turnover to improve care by 10 percentage points, on average, if we were to rely on such improvements alone.

These patterns necessitate a fundamentally different approach to health care human resource management, calling into question typical staffing policies based on qualifications and seniority rather than directly measured quality. J Notarnicola, M; Tutino, V; De Nunzio, V; Dituri, F; Caruso, MG; Giannelli, G Notarnicola, Maria; Tutino, Valeria; De Nunzio, Valentina; Dituri, Francesco; Caruso, Maria Gabriella; Giannelli, Gianluigi Dietary ω -3 Polyunsaturated Fatty Acids Inhibit Tumor Growth in Transgenic Apc^{Min/+} Mice, Correlating with CB1 Receptor Up-Regulation INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES
 English Article olive oil; omega-3 polyunsaturated fatty acids; CB1 receptor; colon cancer; transgenic Apc(Min/+) mice COLORECTAL-CANCER; ADIPOSE-TISSUE; WNT/BETA-CATENIN; OLIVE OIL; COLON; ANANDAMIDE; METABOLISM; THERAPY; OBESITY; CELLS Mediterranean diet components, such as olive oil and omega-3 polyunsaturated fatty acids (omega-3 PUFAs), can arrest cell growth and promote cell apoptosis. Recently, olive oil has been demonstrated to modulate type-1 cannabinoid (CB1) receptor gene expression in both human colon cancer cells and rat colon. The aim of this study was to investigate a possible link between olive oil and omega-3 PUFAs effects and CB1 receptor expression in both intestinal and adipose tissue of Apc(Min/+) mice. To confirm the role for the CB1 receptor as a negative modulator of cell proliferation in human colon cancer, CB1 receptor gene expression was also detected in tumor tissue and in surrounding normal mucosa of patients with colorectal cancer (CRC). Dietary omega-3 PUFAs significantly inhibited intestinal polyp growth in mice, correlating with CB1 receptor gene and protein expression induction. CB1 receptor gene up-regulation was also detected in adipose tissue, suggesting a close communication between cancer cells and the surrounding environment. Tissue CB1 receptor induction was associated with a concurrent inactivation of the Wnt/beta-catenin pathway. Moreover,

there was a significant reduction in CB1 receptor gene expression levels in cancer tissue compared to normal surrounding mucosa of patients with CRC, confirming that in cancer the "protective" action of the CB1 receptor is lost. Chemical profiling of volatile compounds of the essential oil of grey-leaved rockrose (*Cistus albidus* L.) and its antioxidant, anti-inflammatory, antibacterial, antifungal, and anticancer activity in vitro and in silico FRONTIERS IN CHEMISTRY English Article

Cistus albidus L.; essential oil; antioxidant; antimicrobial; anti-inflammatory; anticancer; breast cancer OXIDATIVE STRESS; RISK-FACTORS; EXTRACTS; MECHANISMS; ERGOSTEROL; INHIBITION; CISTACEAE; CARCINOMA; EVOLUTION; EMISSION

Cistus albidus: L., also known as Grey-leaved rockrose and locally addressed as stab or tuzzala lbida, is a plant species with a well-established reputation for its health-promoting properties and traditional use for the treatment of various diseases. This research delves into exploring the essential oil extracted from the aerial components of *Cistus albidus* (referred to as CAEO), aiming to comprehend its properties concerning antioxidation, anti-inflammation, antimicrobial efficacy, and cytotoxicity. Firstly, a comprehensive analysis of CAEO's chemical

composition was performed through Gas Chromatography-Mass Spectrometry (GC-MS). Subsequently, four complementary assays were conducted to assess its antioxidant potential, including DPPH scavenging, beta-carotene bleaching, ABTS scavenging, and total antioxidant capacity assays. The investigation delved into the anti-inflammatory properties via the 5-lipoxygenase assay and the antimicrobial effects of CAEO against various bacterial and fungal strains. Additionally, the research investigated the cytotoxic effects of CAEO on two human breast cancer subtypes, namely, MCF-7 and MDA-MB-231. Chemical analysis revealed camphene as the major compound, comprising 39.21% of the composition, followed by alpha-pinene (19.01%), bornyl acetate (18.32%), tricyclene (6.86%), and melonal (5.44%). Notably, CAEO exhibited robust antioxidant activity, as demonstrated by the low IC₅₀ values in DPPH (153.92 +/- 4.30 μ g/mL) and beta-carotene (95.25 +/- 3.75 μ g/mL) assays, indicating its ability to counteract oxidative damage. The ABTS assay and the total antioxidant capacity assay also confirmed the potent antioxidant potential with IC₅₀ values of 120.51 +/- 3.33 TE μ mol/mL and 458.25 +/- 3.67 μ g AAE/mg, respectively. In terms of anti-inflammatory activity, CAEO displayed a substantial lipoxygenase inhibition at 0.5 mg/mL. Its antimicrobial properties were broad-spectrum, although some resistance was observed in the case of *Escherichia coli* and *Staphylococcus aureus*. CAEO exhibited significant dose-dependent inhibitory effects on tumor cell lines in vitro. Additionally, computational analyses were carried out to appraise the physicochemical characteristics, drug-likeness, and pharmacokinetic properties of CAEO's constituent molecules, while the toxicity was assessed using the Protox II web server.

J Dayioglu, M; Kirdar, MG Dayioglu,
Meltem; Kirdar, Murat Gueray Keeping Kids in School and
Out of Work: Compulsory Schooling and Child Labor in Turkey
JOURNAL OF HUMAN CAPITAL English Article

DEVELOPING-COUNTRIES; CASH
TRANSFERS; EDUCATION; LAWS; CONSEQUENCES; CONSTRAINTS; ENROLLMENT;
RESPONSES; RETURNS; MARKET We examine the effects of a compulsory
schooling reform on child labor in Turkey, which extended the
duration of schooling from 5 to 8 years while substantially
improving the schooling infrastructure. We employ three rounds of
child labor surveys with a very rich set of outcomes. The reform
reduces child labor by 4.6 percentage points (24%) for 12- to 17-
year-olds. For girls, the probability of spending long hours on
household chores also reduces. We find that school enrollment and
child labor are highly substitutable in rural areas but not as
much in urban areas. In addition, the policy effect is stronger
for low-income families. [Dayioglu, Meltem] Middle East Tech

J Fakhreldin, M; Elmasry, K Fakhreldin,
Marwa; Elmasry, Karim Improving the performance of
reflex Human Papilloma Virus (HPV) testing in triaging women with
atypical squamous cells of undetermined significance (ASCUS): A
restrospective study in a tertiary hospital in United Arab
Emirates (UAE) VACCINE English Article

Atypical squamous cells of undetermined significance; High Risk Human Papilloma Virus; Reflex HPV testing; United Arab Emirates; Cervical screening; Triage of ASCUS EXTENDED MIDDLE-EAST; CERVICAL-CANCER; POSTMENOPAUSAL WOMEN; CYTOLOGIC DIAGNOSIS; NATURAL-HISTORY; PREVALENCE; INFECTION; DNA; MANAGEMENT; ABNORMALITIES

Introduction: Cervical cancer is the second commonest cancer in women worldwide. Infection with oncogenic types of human Papillomavirus (HPV) is the most important risk factor for developing cervical cancer. Reflex High risk HPV (HR-HPV) testing is of significant value in the assessment of Papanicolaou (Pap) smear results where ASCUS are identified. **Objective:** To improve the performance of reflex HR-HPV testing in triage of ASCUS and analyze the factors impacting it. **Methodology:** In this study, we generated a database of 9641 women who had cervical smears collected during the study period from the cytopathology record in a large tertiary hospital in UAE. These included 297 smears with ASCUS diagnosis. All cases were retrospectively followed up with a mean duration of 2.44 years. We analyzed data according to the outcome based on several follow-up Pap smear analysis as the reference assessment. **Results:** We detected HR-HPV infection in 17.9% of cases. 9.1% <25, 28.8% 25-34 and 62.1% ≥ 35 years old. HR-HPV prevalence was higher among premenopausal women (20.7%) compared to postmenopausal women (9.5%) (P-value = 0.044). The rate of progression to high grade lesions was also higher (28.7%) in the premenopausal group compared to (12.8%) in the postmenopausal group. Reflex HPV testing had an overall sensitivity of 41.1%, specificity of 88.2%, positive predictive value (PPV) of 62.1%, and negative predictive value (NPV) of 75.9% in detection of cervical lesions. These figures were higher on combining premenopausal status and complaint of abnormal bleeding or discharge/itching (66.7%, 93.3%, 66.8% and 93.3% respectively). **Conclusions:** The sensitivity, specificity and NPV of reflex HPV testing in the triage of ASCUS cases can be more accurate in premenopausal women upon adding age group and presenting complaint as a triage item. This improves the performance of reflex HPV testing and the subsequent selection of high risk patients for colposcopy. (C) 2015 Elsevier Ltd. All rights reserved.  Green Synthesized Silver Nanostructure Using Rhus coriaria
 Fruit Extract Inhibits the Growth of Malignant MCF-7 Cell Line
 BRAZILIAN ARCHIVES OF BIOLOGY AND TECHNOLOGY
 English Article

Cytotoxicity; Green synthesis; Nanostructures; Rhus coriaria; Silver CANCER CELLS; NANOPARTICLES; ANTIBACTERIAL; BIOSYNTHESIS; LEAF; NANOMATERIALS; ANTIOXIDANT; INDICA; PLANT Rhus coriaria, popularly known as sumac, has been used as a spice powder in the Middle East for centuries. It contains a broad range of naturally occurring compounds such as flavonoids, proteins, anthocyanins and volatile oils. It showed a putative importance in treatment of different disorders including cancers. In the current study, R. coriaria fruit extract was used for green synthesis of silver nanostructures (Ag-NSs) and their anticancer activity was tested against human breast cancer cells (MCF-7). The aqueous fruit extract was prepared. The synthesis of Ag-NSs under different conditions was optimized. The optimal reaction medium comprised 1:2 concentration of fruit extract and 3 mM concentration of silver nitrate solution. The green-synthesized Ag-NSs were confirmed by using UV-Visible spectroscopy at a range 300-700 nm, transmission electron microscopy (TEM), X-ray diffraction (XRD) and zeta potential measurements. The anti proliferative activity of Ag-NSs was confirmed with inhibitory activity on MCF-7 cell line growth. The results showed that the IC50 values at 24 and 48h were 14.27 and 13.4 μ g/ml, respectively. In conclusion the results of this study provide a simple, rapid, non-toxic and eco-friendly protocol for green-synthesis of Ag-NSs, which could be used as an alternative and interesting approach for safe and simple synthesis of Ag nanoparticles for biomedical uses. linalool via cancer-specific hydroxyl radical generation in human
colon cancer WORLD JOURNAL OF GASTROENTEROLOGY

English Article

Colorectal cancer; Linalool; Oxidative stress; Electron spin
resonance; Lipid peroxidation SPIN-RESONANCE SPECTROSCOPY;
OXIDATIVE STRESS; COLORECTAL-CANCER; CELLS; IDENTIFICATION;
MITOCHONDRIA; CHEMOTHERAPY; REPERFUSION; ISCHEMIA AIM To
investigate the anticancer mechanisms of the monoterpenoid alcohol
linalool in human colon cancer cells. METHODS The cytotoxic effect
of linalool on the human colon cancer cell lines and a human
fibroblast cell line was examined using the WST-8 assay. The
apoptosis-inducing effect of linalool was measured using the
terminal deoxynucleotidyl transferase dUTP nickend labeling assay
and flow cytometry with Annexin V. Oxidative stress was
investigated by staining for diphenyl-1-pyrenylphosphine, which is
a cellular lipid peroxidation marker, and electron spin resonance
spectroscopy. Sixteen SCID mice xenografted with human cancer
cells were randomized into 3 groups for in vivo analysis: control
and low-dose and high-dose linalool groups. The control group was
administered tap water orally every 3 d. The linalool treatment
groups were administered 100 or 200 μ g/kg linalool solution
orally for the same period. All mice were sacrificed under
anesthesia 21 d after tumor inoculation, and tumors and organs
were collected for immunohistochemistry using an anti-4-
hydroxynonenal antibody. Tumor weights were measured and compared
between groups. RESULTS Linalool induced apoptosis of cancer cells
in vitro, following the cancer-specific induction of oxidative
stress, which was measured based on spontaneous hydroxyl radical
production and delayed lipid peroxidation. Mice in the high-dose
linalool group exhibited a 55% reduction in mean xenograft tumor
weight compared with mice in the control group ($P < 0.05$). In
addition, tumor-specific lipid peroxidation was observed in the in
vivo model. CONCLUSION Linalool exhibited an anticancer effect via
cancer-specific oxidative stress, and this agent has potential for
application in colon cancer therapy. [Iwasaki, Kenichi; Zheng,

 population-based study of selected demographic characteristics of
 Israeli-Jewish women with cervical squamous cell carcinoma
 ARCHIVES OF GYNECOLOGY AND OBSTETRICS English
 Article Cervical squamous
 cell carcinoma; Israeli-Jewish women; Demographic characteristics
 HUMAN-PAPILLOMAVIRUS; RISK-FACTORS; YOUNG-WOMEN; CANCER The
 age-standardized incidence rate (ASR) of invasive cervical cancer
 in Israeli-Jewish women is persistently low compared to many other
 countries. The aim of the present study was to assess selected
 demographic characteristics of Israeli-Jewish women with cervical
 squamous cell carcinoma (SCC) in an attempt to identify current
 selected risk factors. Included were all histologically confirmed
 SCC patients diagnosed during 2002-2004 according to the Israel
 National Cancer Registry. Demographic and population data were

obtained from the Central Population Registry and from the Israel Central Bureau of Statistics annual abstract reports. The ASR and incidence rate for each demographic category were computed. During the study period, 350 SCC patients (mean age 50.3 years) were diagnosed (ASR of 3.8/100,000). High SCC incidence rates of single women 40+, of married women 30+ years old and of divorced and widowed women in the 40-49 age group were found. The mean number of children was 2.1 (range 0-9). Compared to the population the rate of childless patients in the 50+ age group, that of patients with 1-2 children in the 40-49 age group and that of North-African-born patients was significantly higher. No excess rate was found for multiparity and low socioeconomic status. High incidence rates of SCC were observed for some age groups of single and married women, for women without children or 1-2 children and for North-Africa-born women. Great differences between age groups within each demographic category were observed. Microbotanical evidence for the spread of cereal
use during the Mesolithic-Neolithic transition in the Southeastern
Europe (Danube Gorges): Data from dental calculus analysis

JOURNAL OF ARCHAEOLOGICAL SCIENCE English
Article Danube Gorges;
Mesolithic-Neolithic transition; Dental calculus analyses; Diet;
Cereals REMAINS; CONSUMPTION; EMERGENCE; ORIGINS; DIET; FOOD
Research increasingly suggests that natural and social
environments shaped the Neolithic expansion of the farming niche
into Europe. The Danube Gorges, on account of its position between
the Mediterranean and more temperate regions and the presence of
archaeological sites with continuous Mesolithic and Neolithic
layers of occupation associated with vast burial grounds is ideal
for studying the modality of Neolithization. Previous dietary
stable isotope (carbon, nitrogen, and sulphur) studies in the
Central Balkan area indicate that many Neolithic humans remained
reliant on foraged aquatic resources in the Gorges. Until now,
there is no unambiguous evidence of cereal consumption in this
region. The possibility that the rich aquatic resources of the
Danube river habitats within Central Balkans influenced diet and

thus delayed uptake of Neolithic cultigens is unanswered. The extensive skeletal record from sites in the Danube Gorges (Central Balkans) with its long temporal sequence, provides the opportunity to reconstruct plant use during Mesolithic and the Neolithic. To assess when cereals and possibly cultivated plants spread to the region, we analysed the microbotanical remains (starch grains and phytoliths) entrapped in the dental calculus of 81 individuals dating from 9100 to 5500 cal BC, recovered from five sites in the Danube Gorges. This study marks the largest study of dental calculus from this period so far conducted. Added to this, we present new radiocarbon dates ($n = 17$), bone collagen stable isotope data ($\delta^{13}\text{C}$ and $\delta^{15}\text{N}$; $n = 5$) and data on caries frequency. This dietary study identifies that the growing of crops commenced in the Early Neolithic circa 6000 cal BC and was brought by farming migrants of north-western Anatolian ancestry into the Danube Gorges. Despite bringing a Neolithic agm-pastoral subsistence practices and cultural novelties in the Gorges, these migrants and their descendants adopted some of the local dietary and cultural traditions, suggesting a mosaic pattern of Neolithization. The resulting data provides a better understanding of the tempo and spread of cereal agriculture practices and the role of cereals in the diet of Danube Gorges inhabitants.

Emilia Juan, M.; Lozano-Mena, Gloria;
Sanchez-Gonzalez, Marta; Planas, Joana M. Reduction
of Preneoplastic Lesions Induced by 1,2-Dimethylhydrazine in Rat
Colon by Maslinic Acid, a Pentacyclic Triterpene from *Olea*
europaea L. MOLECULES English Article

aberrant crypt foci; colon cancer; mucin
depleted foci; maslinic acid; dimethylhydrazine MUCIN-DEPLETED
FOCI; ABERRANT CRYPT FOCI; COLORECTAL-CANCER; BIOACTIVE COMPOUND;
MEDITERRANEAN DIET; OLEANOLIC ACID; AZOXYMETHANE; CARCINOGENESIS;
CHEMOPREVENTION; APOPTOSIS Maslinic acid triggers compelling
antiproliferative and pro-apoptotic effects in different human
cancer cell lines. Hence, the chemopreventive activity was
investigated on early stages of carcinogenesis induced by 1,2-
dimethylhydrazine (DMH) which is a model that mimics human
sporadic colorectal cancer. Male Sprague-Dawley rats were orally
administered either maslinic acid at 5, 10 or 25 mg/kg dissolved
in (2-hydroxypropyl)--cyclodextrin 20% (w/v) or the solvent for 49
days. After one week of treatment, animals received three weekly
intraperitoneal injections of DMH at the dose of 20 mg/kg.
Maslinic acid reduced the preneoplastic biomarkers, aberrant crypt
foci (ACF) and mucin-depleted foci (MDF), already at 5 mg/kg in a
15% and 27%, respectively. The decline was significant at 25 mg/kg
with decreases of 33% and 51%, respectively. Correlation analysis
showed a significant association between the concentrations of
maslinic acid found in the colon and the reduction of ACF ($r =$
0.999, $p = 0.019$) and MDF ($r = 0.997$, $p = 0.049$). The present
findings demonstrate that maslinic acid induced an inhibition of
the initiation stages of carcinogenesis. The assessment of this
pentacyclic triterpene at the colon sheds light for designing
diets with foods rich in maslinic acid to exert a chemopreventive
activity in colorectal cancer. [Emilia Juan, M.; Lozano-Mena,

J De Marco, F; Houissa-Kchouk, F; Khelifa, R; Marcante, ML
De Marco, Federico; Houissa-Kchouk, Fatma;
Khelifa, Ridha; Marcante, Maria Luisa High-risk HPV
types in Tunisia. A pilot study reveals an unexpectedly high
prevalence of types 58 and 82 and lack of HPV 18 among female
prostitutes JOURNAL OF MEDICAL VIROLOGY English
Article epidemiology; HPV
epidemiological pockets; mediterranean area; multivalent HPV
vaccine formulation; cervical cancer prevention and screening
HUMAN-PAPILLOMAVIRUS TYPES; CERVICAL LESIONS; CANCER; DNA;
CLASSIFICATION; AMPLIFICATION; VACCINATION; INFECTION; PRIMERS
"High-risk" HPVs (HR-HPV) have sharply different prevalences
and there is evidence to suggest this may vary according to
regions. Accurate description of HR-HPV circulation is a key
feature for the rational design of prevention and screening
campaigns. To gain insight into HR-HPV circulation in Tunisia, a
pilot study was carried out on 64 healthy prostitutes working in
the Tunis area. HPV detection and typing were carried out by
MY09/MY11 PCR and restriction fragment length polymorphism (RFLP).
A selected set of samples was also assayed by Gp5+/Gp6+ PCR and
typed by direct sequencing. Out of 64 women, 28 were HPV positive.
HPV-16 and HPV58, both members of the genus Alpha-Papillomavirus,
species 9, accounted for 10 and 7 cases with a prevalence rate of
38% and 27%, respectively. HPV-82, a member of species 5, ranked
third with four cases (similar to 15%). Types 31, 33, 35; all
members of species 9 were each detected once (similar to 4%) while
neither HPV-18 nor related members of species 7 were detected.
Type 72 and 83, both members of species 3, were the only low-risk
types, each detected only once (4% each). Two samples could not be
typed. The prevalence of HPV types appeared sharply different from
that of neighboring areas. Should the existence of epidemiological
pockets be confirmed by larger, more detailed studies, screening
and vaccine campaigns will have to be designed carefully taking
into account the actual epidemiological context of the target
population. Regina Elena Inst Canc Res, Virol Lab, I-00158 Rome,

 Estimating the indirect economic burden of cancer in Jordan:
 a retrospective observational study BMJ OPEN
 English Article health
 economics; health policy; oncology COST; ELASTICITIES;
 DISABILITY; VALUES; CARE Objective The aim of this study is to
 estimate the indirect economic burden of 22 cancer types in Jordan
 using both the human capital approach (HCA) and the value of a
 statistical life year (VSLY) approach. Additionally, this study
 aims to forecast the burden of these cancers for the next 5 years
 while employing time series analysis. Design Retrospective
 observational study with a time series analysis. Participants
 Disability adjusted life years records from the IHME Global Burden
 Disease estimates 2019 data. Primary outcome measure Indirect
 economic burden of cancer in Jordan. Results The mean total
 economic burden for all cancers is estimated to be \$1.82 billion
 using HCA and \$3.13 billion using VSLY approach. The cancers
 contributing most to the total burden are 'tracheal, bronchus and
 lung cancer' (\$359.5 million HCA, \$618.3 million VSLY), followed
 by 'colon and rectum cancer' (\$300.6 million HCA, \$517.1 million
 VSLY) and 'breast cancer' (\$292.4 million HCA, \$502.9 million
 VSLY). The indirect economic burden ranged from 1.4% to 2.1% of
 the gross domestic product (GDP) using the HCA, and from 2.3% to
 3.6% of the GDP using the VSLY approach. The indirect economic
 burden is expected to reach 2.3 and 3.5 billion Intl\$ by the year
 2025 using the HCA and VSLY approach, respectively. Conclusion The
 indirect economic burden of cancer in Jordan amounted to 1.4%-3.6%
 of total GDP, with tracheal, bronchus and lung cancer; colon and
 rectum cancer; and breast cancer contributing to over 50% of the
 total burden. This will help set national cancer spending
 priorities following Jordan's economic modernisation vision with
 regard to maximising health economic outcomes. [Rashdan, Omar]

incidence in 13 European countries: Changing risk and the effects
of screening

CANCER EPIDEMIOLOGY BIOMARKERS & PREVENTION
English Article

INTERNATIONAL INCIDENCE RATES; BIRTH COHORT PATTERNS; CANCER
MORTALITY; HUMAN-PAPILLOMAVIRUS; AGE-PERIOD; TEMPORAL VARIATION;
UTERINE CERVIX; ADENOCARCINOMA; ENGLAND; INCREASE Despite there
being sufficient evidence for the effectiveness of screening by
cytology in preventing cancer of the cervix uteri, screening
policies vary widely among European countries, and incidence is
increasing in younger women. This study analyzes trends in
squamous cell carcinoma (SCC) of the cervix uteri in 13 European
countries to evaluate effectiveness of screening against a
background of changing risk. Age-period-cohort models were fitted
and period and cohort effects were estimated; these were
considered as primarily indicative of screening interventions and
changing etiology, respectively. A unique set of estimates was
derived by fixing age slopes to one of several plausible age
curves under the assumption that the relation between age and
cervical cancer incidence is biologically determined. There were
period-specific declines in cervical SCC in several countries,
with the largest decreases seen in northern Europe. A pattern
emerged across Europe of escalating risk in successive generations
born after 1930. In the western European countries, a decrease
followed by a stabilization of risk by cohort was accompanied by
period-specific declines. In southern Europe, stable period, but
increasing cohort trends, were observed. Substantial changes have
occurred in cervical SCC incidence in Europe and well-organized
screening programs have been highly effective in reducing the
incidence of cervical SCC. Screening and changing sexual mores
largely explain the changing period- and cohort-specific patterns,
respectively. The increasing risk in recent cohorts is of obvious
concern particularly in countries where no screening programs are
in place. Further investigation of the effectiveness of
opportunistic screening is warranted as is the observation of
differing risk patterns in young cohorts in countries with
relatively similar societal structures. Int Agcy Res Canc,

K.; Jirjees, Feras J. Knowledge and awareness about
human papillomavirus infection and its vaccination among women in
Arab communities SCIENTIFIC REPORTS English

Article CERVICAL-
CANCER; HPV VACCINE; MIDDLE-EAST; ATTITUDES Cervical cancer (CC)
is one of the most common types of cancer that affect females
worldwide with hundreds of thousands of women dying annually due
to this disease, mainly in developing countries. Infection with
human papillomavirus (HPV) is the main risk factor for this
cancer. There are no public awareness and national immunization
programs in most Arab countries. This study aimed to investigate
the knowledge and awareness about the HPV vaccine among females in
four Arab countries and their acceptance to receive the vaccine. A
cross-sectional study was conducted in several Arab countries:
Jordan, Qatar, the United Arab Emirates (UAE), and Iraq.
Respondents that fulfilled the desired criteria and were willing
to participate in the study were asked to fill out the survey.
Knowledge and awareness were assessed using 13 questions. Ethical
approvals were given from the four countries. A total of 3658
individuals participated in the study; however, 2804 responses
were included in the analysis and more than one third of
participants (n = 1007) were aged between 18 and 25 years old.
This study revealed poor awareness and knowledge of the
participants about HPV and its vaccine among all four countries'
participants with relatively better knowledge among participants
from the UAE. Participants who are younger (18-25 years old), have
a postgraduate education, have an education or career related to
the medical field, or had a Pap smear in the last three years tend
to have higher knowledge about the HPV vaccine compared to others.
Poor knowledge and awareness findings in this study were expected,
considering the lack of public education campaigns regarding the
HPV virus coupled with the absence of the HPV vaccination from the
national immunization schedule in three participating countries
(Jordan, Qatar, and Iraq). It is recommended that there is a need
to provide national educational campaigns about the HPV vaccine to
the public in all Arab populations. [Alsous, Mervat M.]

J Nuzzolese, E; Di Vella, G Nuzzolese, Emilio; Di Vella, Giancarlo Forensic dental investigations and age assessment of asylum seekers

INTERNATIONAL DENTAL JOURNAL English Article forensic odontology; dental age estimation; asylum seekers; human rights Age estimation is useful in forensic investigations to aid in the process of identifying unknown victims as well as living individuals. In many countries age estimation is commonly used to assist immigration authorities in deciding whether refugees or illegal migrants have reached that designated age that separates a juvenile from an adult. This is particularly important for the protection of unaccompanied minors. Italy is a country of great appeal for immigration as people from other Mediterranean countries can easily reach Italian coasts. In Italy, as in other western world countries, unaccompanied asylum seekers deemed to be under 18 face a very different path-through the immigration system. They cannot be deported and are sent through a juvenile system where they have access to education programmes and may be granted a residence permit. The Section of Legal Medicine of the University of Bari was approached by Judges and Immigration Police with the question to assess the age of unaccompanied asylum seekers who claim to be below 18 years of age. The contribution of forensic odontologists for age estimation was recognised and since November 2006 age estimation of asylum seekers in Bari (Italy) relies on clinical and dental examination together with skeletal maturation as seen on radiographs of the left hand and wrist, the pelvis for iliac crests and root development and mineralisation of third molars as seen on an orthopantomogram. of Cervical Squamous Cell Carcinoma during Pregnancy: A Case
Report MIDDLE EAST JOURNAL OF CANCER English
Article Cervix; Neoadjuvant
chemotherapy; Pregnancy; Squamous cell carcinoma RADICAL
TRACHELECTOMY; PROGNOSTIC-FACTORS; CANCER; VAGINA; MANAGEMENT
Squamous cell carcinoma is one of the common malignancies
among women, especially in the third and fourth decades of life.
Human papillomavirus is the most important cause of squamous cell
carcinoma among women worldwide. Early diagnosis and treatment of
this carcinoma can prevent disease progression. Herein, we present
the case of a pregnant woman with squamous cell carcinoma. A 35-
year-old pregnant woman referred to our clinic for cervical
cerclage. During the procedure, the gynecological surgeon observed
a suspicious lesion. Accordingly, cervical conization was
performed and a squamous cell carcinoma lesion was confirmed by
the pathology reports. Neoadjuvant chemotherapy was initiated for
the patient during pregnancy. Radical hysterectomy and bilateral
lymphadenectomy were conducted toward caesarean section. As the
patient was a young fertile woman, the ovaries were saved.
Although chemotherapy is not a standard treatment for cervical
cancer in pregnancy, but neoadjuvant chemotherapy followed by
radical hysterectomy and bilateral pelvic lymphadenectomy during
cesarean section was a successful treatment in our patient.

Genital Human Papillomavirus Infection and Genotype
Prevalence Among Albanian Women: A Cross-Sectional Study JOURNAL

HPV 81; HPV 53; HPV 56; Mediterranean area; HPV vaccine formulation; cervical cancer prevention and screening GRADE CERVICAL LESIONS; HPV TYPES; DNA; CLASSIFICATION; AMPLIFICATION; CANCER "High risk" HPV types have different geographical distribution and evidence suggests their respective prevalence may vary in different areas and regions. An accurate description of high-risk HPV circulation is a key feature for the rational design of prevention and screening campaigns. A cross-sectional, virological study was conducted on adult Albanian women living either in the Tirana area or in the Duresh prefecture. Clinical and gynecological evaluations were performed according to current standard criteria. HPV detection and typing were carried out by a combined MY09/MY11 and GP5+/GP6+ PCR followed by direct sequencing of generated amplicons. Virological data were obtained from 402 out of 452 patients enrolled between January 2004 and December 2007. Sixty-one patients (15.1% of the cohort) were found to be infected with a genital HPV. As expected, viral prevalence was higher among women younger than 30 years of age (25.2%) in comparison to those aged 30 or older (13.6%). HPV 16 was found to be the most frequent type (41% of cases), followed by HPV 53 (7.2%), HPV 31 (5.8%), and HPV 18 (4.3%). HPV 81 and HPV 84 were the most prevalent low-risk types detected with prevalences of 11.6% and 5.8%, respectively. No differences were noted in any type-specific prevalence between young and mature women. The circulation of HPV types is far more complex than assumed generally. Detailed knowledge of HPV type circulating patterns in specific local geographical areas is essential for appropriate implementation of screening, prevention, and surveillance campaigns. J. Med. Biomarker to Predict Short Term Prognosis of Low Grade Cervical Intraepithelial Neoplasia in Human Papilloma Virus Negative and Positive Patients MIDDLE EAST JOURNAL OF CANCER

English Article

KI-67

biomarker; HPV infection prognosis; Cervical intraepithelial neoplasia; Immunohistochemistry HPV TEST; P16/KI-67; CYTOLOGY; KI-67; EXPRESSION; PROTEIN; WOMEN Background: Cervical cancer is the most common gynecologic cancer in developing countries. Although this malignancy is preventable, problems exist with screening this cancer. Numerous studies have researched immunohistochemistry methods, such as the KI-67 biomarker as a proliferation marker, to improve screening for cervical intraepithelial neoplasia as the precancerous phase of cervical cancer. These studies mostly screened cytological samples. In the current study, we sought to analyze the correlation between the KI-67 proliferative biomarker and HPV infection in order to predict short-time prognosis in cervical intraepithelial neoplasia as an alternative or ancillary method to current screening methods. Our assessment was based on histologic samples from a different geographic population. Methods: This descriptive cohort prospective study included 40 patients diagnosed with low grade cervical intraepithelial neoplasia based on cervical punch biopsy samples after colposcopy examination. We enrolled patients who referred to the Department of GynecologyOncology of an academic hospital of Mashhad University of Medical Sciences from 2016 to 2017. All low grade cervical intraepithelial neoplasia samples were investigated for HR-HPV DNA with the Cobas test and immunostaining for the KI-67 biomarker. After a one-year follow-up, we evaluated the prognosis for all patients based on liquid based cytology and HR-HPV test. Data were analyzed by SPSS version 23.0 and the Mann-Whitney U and Fisher's exact tests. A P-value < 0.05 was considered significant. Results: We observed a significant difference between HR-HPV positive and negative tests in KI-67 expression ($P < 0.001$), but there were no significant differences in reactivity level of cervical epithelium ($P=0.5$) and in KI-67 expressions in metaplastic and non-metaplastic epithelium ($P= 0.88$). After one year, most low grade cervical intraepithelial neoplasia cases in group A that had a low staining KI-67 biomarker had evidence of regression. On the contrary, all cases with high grade KI-67 expression didn't persist or progressed necessarily. Conclusion: The KI-67 biomarker is recommended as a complementary screening test, but not an alternative for triage of high-risk patients with low grade cervical intraepithelial neoplasia. Patients with low grade cervical intraepithelial neoplasia/HR-HPV positive cervical samples and low staining KI-67 antigen could be offered a less aggressive follow-up protocol. ADVANCES IN CANCER BIOLOGY-METASTASIS English

Article Plant miRNAs;
Epithelial-mesenchymal transition; Tumorigenesis; Moringa oleifera; Cross -kingdom regulation; Proteomics CERVICAL-CANCER; SERUM-ALBUMIN; DRUG-RESISTANCE; PLANT; MIGRATION; SURVIVAL; GROWTH; ACTB; EMT Cervical cancer (CC) is one of the most frequent cancers in women worldwide. The epithelial-mesenchymal transition (EMT) and the extracellular release of TGF-beta are phenomena typically associated with different tumorigenic processes, including tumour cell proliferation and metastatization. Specific human microRNAs (miRNAs; miRs) involved in these tumorigenic processes have been identified, becoming important diagnostic and prognostic markers, and even potential therapeutic targets. In parallel, different studies have also shown that plant miRNAs can mediate a cross-kingdom regulation (CKR) of mammalian genes and modulate host's gene expression under pathological conditions, restoring the regulatory activity of endogenous miRNAs lost in cancer. In our previous studies, the miRNome from Moringa oleifera Lam. (henceforth moringa or mol) has been sequenced, showing the presence of several conserved miRNAs in the plant kingdom, whose ability to differentially regulate proliferation and apoptosis in healthy and cancer cells has been demonstrated. Furthermore, the effects of mol-miR treatment on tumorigenesis and EMT have been proved in liver tumour cells. According to these premises, we here investigated the proteomic profile of CC-derived HeLa cells exposed to a mol-miRNA pool, demonstrating the down-representation of specific factors involved in tumorigenesis. The treatment with plant miRs was able to modulate proteins involved in several biological processes linked to EMT. Furthermore, it reduced the expression of TGF-beta and significantly inhibited cell motility, as observed following Scratch test and cell viability measurements, with a significant increase of apoptotic events. In conclusion, our results suggest and pave the way for the development of new potential therapeutic approaches based on CKR mediated by plant miRNAs for contrasting human cervical cancer, even in the form of adjuvants to classic treatments for limiting their side effects. cytology; PCR based sequencing ATYPICAL GLANDULAR CELLS;
 GENOTYPE DISTRIBUTION; SQUAMOUS-CELLS; PREVALENCE; LESIONS; DNA;
 SMEARS; HPV; AGE; WORLDWIDE This study investigates the
 distribution of human papillomavirus (HPV) in women with abnormal
 cervical cytology in Kuwait. Two hundred and ninety-eight (298)
 abnormal ThinPreps were taken from women seeking routine
 gynecological care and screened for HPV DNA by real-time PCR. HPV
 genotyping was determined by PCR-based sequencing. HPV DNA was
 detected in 152 women (51%), and 29 different HPV genotypes were
 detected, comprising 16 high-risk (HR) (16, 18, 31, 33, 35, 39,
 45, 51, 53, 56, 58, 59, 66, 68, 73, 97), nine low-risk (LR) (6,
 11, 54, 61, 74, 81, 90, 102, 106), and four intermediate-risk (IR)
 (62, 67, 84, 87). HPV16 had the highest prevalence (24.3%),
 followed by HPV11 (13.8%), HPV66 (11.2%), HPV33 (9.9%), HPV53
 (9.2%), HPV81 (9.2%), HPV56 (7.9%) and HPV18 (6.6%). HPV
 prevalence was 86, 67, and 89% in women with invasive cervical
 carcinoma (ICC), high-grade squamous intraepithelial lesion (HSIL),
 and low-grade squamous intraepithelial lesion (LSIL),
 respectively. As for age distribution, 69% of all HPVs were found
 in women aged 20-29 years, and the HPV incidence rate decreased with
 increasing age. The proportion of single infections decreased as
 the severity of the cytological diagnosis increased, while the
 proportion of multiple infections increased. This study is the
 first of its type in Kuwait and one of few in the Middle East. The
 findings are consistent with the hypothesis that HPV infection is
 the primary cause of cervical neoplasia. They support HPV vaccine
 research to prevent cervical cancer and efforts to develop HPV DNA
 diagnostic tests. Diagn. Cytopathol. 2013. (c) 2011 Wiley

Prevalence of Human Papillomavirus Among Women With Normal
Cervical Cytology in Kuwait JOURNAL OF MEDICAL VIROLOGY

English Article

HPV

infection; normal cervical cytology; PCR based sequencing; age
specific distribution GENITAL HUMAN-PAPILLOMAVIRUS; RISK-FACTORS;
INFECTION; HPV; WORLDWIDE; CANCER; SMEARS; PCR; DNA; ABNORMALITIES

This study was undertaken to determine the prevalence and
type specific distribution of human papillomavirus (HPV) in women
with normal cervical cytology in Kuwait. The study is the first of
its type in Kuwait and one of few in the Middle East. The age
specific distribution of HPV types was determined in 3,011

ThinPrep samples taken from women seeking routine gynaecological
care. ThinPrep samples were screened for HPV DNA by real-time PCR.
The type specific distribution of the viruses was determined by
PCR-based sequencing. The results showed that HPV DNA was detected
in 71 women (2.4%), and 21 different HPV genotypes were detected,
comprising eight high-risk (HR) (16, 31, 33, 53, 56, 58, 66, and
73), seven low-risk (LR) (6, 11, 54, 61, 70, 81, and 90), four
intermediate-risk (IR) (67, 82, 83, and 84) and HPV 102 and HPV
106. LR HPV types were found in 71.8% of infected samples, HR
types in 32.3%, and IR types in 7%. With regard to age, 40.8% of
all HPVs were found in women 30-39 years of age, 29.6% in women
40-49 years of age, 19.7% in women over 50 years and 9.9% in women
less than 34 years old. The study shows that the prevalence of HPV
infection in Kuwait is among the lowest in the world and suggests
that HPV vaccine could prevent the development of HPV associated
cervical cancer in 1.39% of young females living in Kuwait.

However, more extensive population-based studies should be
undertaken before implementing HPV vaccination. J. Med. Virol.

Adenovirus Infection in Hospitalized Children with Acute Respiratory Infection in Jordan

PEDIATRIC INFECTIOUS DISEASE JOURNAL

English

Article

adenovirus;

adenovirus types; adenovirus species; acute respiratory illness; viral co-detection COMMUNITY-ACQUIRED PNEUMONIA; MOLECULAR EPIDEMIOLOGY; SYNCYTIAL VIRUS; UNITED-STATES; SURVEILLANCE; IDENTIFICATION; IMMUNOCOMPETENT Background: The most common clinical manifestation of adenovirus (AdV) infection is acute respiratory illness (ARI). Specific AdV species associated with ARI hospitalizations are not well defined in the Middle East. Methods: A viral surveillance study was conducted among children <2 years hospitalized in Amman, Jordan, from March 2010 to March 2013. Nasal and throat respiratory specimens were obtained from enrolled children and tested for viruses using a real-time reverse-transcription quantitative polymerase chain reaction. AdV-positive specimens were typed by partial hexon gene sequencing. Demographic and clinical features were compared between AdV detected as single pathogen versus co-detected with other respiratory viruses, and between AdV-B and AdV-C species. Results: AdV was detected in 475/3168 (15%) children hospitalized with ARI; of these, 216 (45%) specimens were successfully typed with AdV-C as the most common species detected (140/216; 65%). Children with AdV-single detection (88/475; 19%) had a higher frequency of fever (71% vs. 56%; $P=0.015$), diarrhea (18% vs. 11%; $p=0.048$), and/or seizures/abnormal movements (14% vs. 5%; $p=0.003$). Children with AdV co-detected with other viruses more likely required oxygen support [adjusted odds ratio (aOR) 1.91 (95% CI: 1.08, 3.39), $P = 0.027$] than those with AdV-single detection. Children with AdV-C had higher odds of co-detections with other viruses compared with those with AdV-B [aOR 4.00 (95% CI: 1.91, 8.44), $P < 0.001$]. Conclusion: Clinical differences were identified between AdV-single and AdV co-detected with other viruses, and between AdV-B and AdV-C. Larger studies with AdV typing are needed to determine additional epidemiological and clinical differences between specific AdV species and types. Ancestral modal Y-STR haplotype shared among Romani and South Indian populations

GENE

English

Article

Y-STRs; Y-SNPs; Romani; Roma;

Serbia; Phylogenetic analyses

PHYLOGEOGRAPHIC ANALYSIS;

MIGRATORY EVENTS; VLAX ROMA; GENE FLOW; CHROMOSOME; RESOLUTION;

ORIGIN; DIFFUSION; HERITAGE; HISTORY

One of the primary

unanswered questions regarding the dispersal of Romani populations

concerns the geographical region and/or the Indian caste/tribe

that gave rise to the proto-Romani group. To shed light on this

matter, 161 Y-chromosomes from Roma, residing in two different

provinces of Serbia, were analyzed. Our results indicate that the

paternal gene pool of both groups is shaped by several strata, the

most prominent of which, H1-M52, comprises almost half of each

collection's patrilineages. The high frequency of M52 chromosomes

in the two Roma populations examined may suggest that they descend

from a single founder that has its origins in the Indian

subcontinent. Moreover, when the Y-STR profiles of haplogroup H

derived individuals in our Roma populations were compared to those

typed in the South Indian emigrants from Malaysia and groups from

Madras, Karnataka (Lingayat and Vokkaliga castes) and tribal

Soligas, sharing of the two most common haplotypes was observed.

These similarities suggest that South India may have been one of

the contributors to the proto-Romanis. European genetic signatures

(i.e., haplogroups E1b1b1a1b-V13, G2a-P15, I-M258, J2-M172 and R1-

M173), on the other hand, were also detected in both groups, but

at varying frequencies. The divergent European genetic signals in

each collection are likely the result of differential gene flow

and/or admixture with the European host populations but may also

be attributed to dissimilar endogamous practices following the

initial founder effect. Our data also support the notion that a

number of haplogroups including G2a-P15, J2a3b-M67(xM92), I-M258

and E1b1b1-M35 were incorporated into the proto-Romani paternal

lineages as migrants moved from northern India through

Southwestern Asia, the Middle East and/or Anatolia into the

Balkans. (c) 2012 Elsevier B.V. All rights reserved. [Herrera,

3-Phosphoinositide-Dependent Kinase 1 Potentiates Upstream Lesions on the Phosphatidylinositol 3-Kinase Pathway in Breast Carcinoma CANCER RESEARCH English

Article

REGULATING

CELL-MIGRATION; PROTEIN-KINASE; PIK3CA MUTATIONS; PDK1; ACTIVATION; CANCER; PTEN; ONCOGENE; AMPLIFICATION; AKT1 Lesions of ERBB2, PTEN, and PIK3CA activate the phosphatidylinositol 3-kinase (PI3K) pathway during cancer development by increasing levels of phosphatidylinositol-3,4,5-triphosphate (PIP3). 3-Phosphoinositide-dependent kinase 1 (PDK1) is the first node of the PI3K signal output and is required for activation of AKT. PIP3 recruits PDK1 and AKT to the cell membrane through interactions with their pleckstrin homology domains, allowing PDK1 to activate AKT by phosphorylating it at residue threonine-308. We show that total PDK1 protein and mRNA were overexpressed in a majority of human breast cancers and that 21% of tumors had five or more copies of the gene encoding PDK1, PDPK1. We found that increased PDPK1 copy number was associated with upstream pathway lesions (ERBB2 amplification, PTEN loss, or PIK3CA mutation), as well as patient survival. Examination of an independent set of breast cancers and tumor cell lines derived from multiple forms of human cancers also found increased PDK1 protein levels associated with such upstream pathway lesions. In human mammary cells, PDK1 enhanced the ability of upstream lesions to signal to ART, stimulate cell growth and migration, and rendered cells more resistant to PDK1 and PI3K inhibition. After orthotopic transplantation, PDK1 overexpression was not oncogenic but dramatically enhanced the ability of ERBB2 to form tumors. Our studies argue that PDK1 overexpression and increased PDPK1 copy number are common occurrences in cancer that potentiate the oncogenic effect of upstream lesions on the PI3K pathway. Therefore, we conclude that alteration of PDK1 is a critical component of oncogenic PI3K signaling in breast cancer. Chemopreventive properties of pinorexinol-rich olive oil involve a selective activation of the ATM-p53 cascade in colon cancer cell lines CARCINOGENESIS English

Article COLORECTAL-

CANCER; PHENOLIC-COMPOUNDS; GASTROINTESTINAL CANCERS; CYCLE ARREST; P53 NETWORK; APOPTOSIS; PATHWAY; PHOSPHORYLATION; HYDROXYTYROSOL; PREVENTION The Mediterranean diet is rich in extra virgin olive oil (EVOO) and associated with a lower incidence of colorectal cancer. EVOO contains phenolic extracts with potential anticarcinogenic activity. Aim: To assess the anticancer properties of EVOO phenolic extracts using in vitro models. Methods: Phenolic profiles of two different EVOOs (A and B) were determined. RKO and HCT116 (both p53 proficient), SW480 (p53 mutant) and HCT116(p53-/-) (p53 knocked out) cell lines were treated with EVOO extracts and assessed for cell viability. Apoptosis was determined by terminal deoxynucleotidyl transferase nick end labeling (TUNEL) assay and changes in Bax transcript levels. Cell cycle analysis was determined by flow cytometry and western blots. To confirm the data, analysis of cell viability and cell cycle was performed with purified pinorexinol. Results: Chemical characterization showed that pinorexinol is the main phenol in EVOO-A, and oleocanthal predominates in EVOO-B. Only EVOO-A affected cell viability, which was significantly more pronounced in p53-proficient cells. At a concentration of 200 nM, p53-proficient cells showed increased apoptosis and G(2)/M arrest. In p53-proficient cells, ataxia telangiectasia mutated (ATM) and its downstream-controlled proteins were upregulated after treatment, with a parallel decrease of cyclin B/cdc2. Identical results on cell viability and cell cycle were obtained with purified pinorexinol, but this required a higher concentration than in EVOO-A. Conclusion: Our results demonstrate that pinorexinol-rich EVOO extracts have potent chemopreventive properties and specifically upregulate the ATM-p53 cascade. This result was achieved at substantially lower concentrations in EVOO than with purified pinorexinol, indicating a possible synergic effect between the various polyphenols in olive oil. Apoptotic activity of the marine diatom *Cocconeis scutellum* and eicosapentaenoic acid in BT20 cells PHARMACEUTICAL BIOLOGY

English Article

Apoptosis; caspases; polyunsaturated fatty acids SEX REVERSAL; FATTY-ACIDS; CANCER; CRUSTACEA; DEATH Context: The marine diatoms *Cocconeis scutellum* Ehrenberg (Bacillariophyceae) are known to trigger apoptosis in the androgenic gland of the Mediterranean crustacean *Hippolyte inermis* Leach (Decapoda), affecting the shrimp's sex reversal. Objective: The aim of this study was to evaluate a possible apoptotic effect of extracts and fractions from these microalgae also on human tissues. Materials and methods: The chemical profile of *C. scutellum* was determined by gas chromatography-mass spectrometry (GC-MS) and, afterwards, organic extracts and fractions from the diatoms were used to treat to breast cancer BT20 cells. Double labeling with annexin V-FITC and isotonic propidium iodide (PI) along with flow cytometry analysis enabled the evaluate of cell apoptosis and viability, whereas hypotonic PI staining was used to analyze the cell cycle in BT20 lines. The involvement of specific caspases was studied by Western blotting. Results: Results demonstrated that the diethyl ether extract and, in particular, fraction 3, the richest fraction in eicosapentaenoic acid (EPA) from the diethyl ether extract, selectively induced apoptosis (up to 89.2% at 1 μ g/well of fraction 3) and decreased viability in BT20 cells. The apoptotic effect was displayed in a concentration and time-dependent manner, by activating caspases-8 and 3, and arresting the progression of the cell cycle from S to G2-M phase. EPA alone showed similar

apoptotic effects in BT20 cells. Discussion and conclusion: The study demonstrates the apoptotic activity of *C. scutellum* diatoms on breast cancer cells and suggests their potential use as a source of apoptotic compounds. papillomavirus spectrum of HPV-infected women in Nigeria: an
analysis by next-generation sequencing and type-specific PCR

VIROLOGY JOURNAL English Article

HPV types; Spectrum; Nigeria; Next-generation sequencing; Polymerase chain reaction CERVICAL-CANCER; DNA-REPLICATION; MIDDLE-EAST; RISK; PREVALENCE; IDENTIFICATION; GENOTYPES BackgroundHuman papillomavirus (HPV) infection and cervical cancer are leading health problems and causes of death in many parts of the world. There are similar to 200 HPV types that can infect humans. This study aims to understand the spectrum of HPV infections in Nigerian women with normal or abnormal cytology. MethodsWe screened cervical samples from 90 women with possible HPV infections collected in two regional hospitals in Nigeria. The first screening was done using next-generation DNA sequencing (NGS), identifying multiple HPV types in many samples. Thereafter, type-specific PCR analysis was used to verify the NGS-identified HPV types in each sample. ResultsNGS analysis of the 90 samples from the Nigerian

cohort identified 44 HPV types. The type-specific PCR confirmed 25 HPV types out of the 44 HPV types detected by NGS, and similar to 10 of these types were the most prevalent. The top five prevalent types found in the Nigerian cohort were HPV71 (17%), HPV82 (15%), HPV16 (16%), HPV6 (10%), and HPV20 (7%). Among the PCR-confirmed HPV types, we found 40.98% high-risk HPV types, 27.22% low-risk HPV types, and 31.15% undetermined HPV types. Among these 25 HPV types in Nigeria, only six were included in the current nine-valent HPV vaccine. We also observed strikingly high multiple HPV infections in most patients, with as many as nine HPV types in a few single samples. Conclusions Our NGS-PCR approach of HPV typing in the Nigerian cohort samples unveiled all possible HPV types currently circulating in Nigerian people. We confirmed 25 HPV types using NGS and PCR, with many samples infected with multiple HPV types. However, only six of these types are part of the nine-valent HPV vaccines indicating the need to develop region-specific selective vaccines. Antitumor Activity of Ethanolic Extract from *Thymra*

Spicata L. aerial Parts: Effects on Cell Viability and

Proliferation, Apoptosis Induction, STAT3, and NF- κ B Signaling

NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL

English Article

NITRIC-OXIDE; ESSENTIAL OILS; IN-VITRO; NATURAL POLYPHENOLS; MEDICINAL-PLANTS; CANCER; PRODUCTS; INFLAMMATION; INHIBITION; MODULATION Thyme-like plants including *Thymra spicata* L. are widely used as food and folk medicinal remedies in the Mediterranean area. This study aimed to explore the in vitro antitumor potential of polyphenol-enriched extracts from aerial parts of *T. spicata*. The ethanolic extract significantly inhibited proliferation of different human tumor cell lines, without significant effects on non-neoplastic cells. A deeper

investigation of the molecular mechanism sustaining the in vitro antitumor activity of the extract was carried on the human breast cancer cells MCF-7 in comparison with the normal breast cells MCF-10A. The effects on MCF-7 cells were associated with the following: (i) production of reactive oxygen species (ROS) and release of nitric oxide; (ii) apoptosis induction; and (iii) reduction in STAT3 and NF- κ B phosphorylation. The ethanolic extract from *T. spicata* leaves might represent a novel therapeutic tool in combination with conventional chemotherapy to reduce the adverse side effects and drug resistance. Dittrichia viscosa L. Leaves: A Valuable Source of Bioactive Compounds with Multiple Pharmacological Effects MOLECULES English Article

phytochemicals; antioxidants; antidiabetic; antibacterial; antiglycation; cytotoxicity ANTIOXIDANT ACTIVITY; ALPHA-GLUCOSIDASE; ESSENTIAL OILS; EXTRACTS; ACID; APOPTOSIS; AMYLASE This work focused on the leaves of *Dittrichia viscosa*, a plant used in Mediterranean folk medicine. Compared to water extract, the methanolic extract had higher antioxidant effects. Moreover, this extract showed potent in vitro inhibitory activity against alpha-amylase and alpha-glucosidase and showed an interesting antiglycation effect. Additionally, the evaluation of the cytotoxic activity of the methanolic extract against two human breast cancer cell lines, MCF-7 and MDA-MB-468, was very promising, with no cytotoxicity towards normal cells (peripheral blood mononuclear cells (PBMCs)). The antibacterial effect was also

assessed and showed potent inhibitory activity against *Proteus mirabilis* and *Bacillus subtilis*. On the other hand, *Dittrichia viscosa* leaves were rich in macro-elements containing appropriate micro-elements and high levels of phenolics and flavonoids such as caffeic acid derivatives. Taken together, the results obtained in this study indicate that *Dittrichia viscosa* could constitute a valuable source of bioactive molecules and could be used either on the preventive side or for therapeutic applications without toxicity. Factors Associated with Longitudinal Changes in Mammographic
Density in a Multiethnic Breast Screening Cohort of Postmenopausal
Women BREAST JOURNAL English Article

CANCER-RISK; MEDITERRANEAN POPULATION;
CUMULATIVE NUMBER; HORMONE-THERAPY; OOPHORECTOMY; TAMOXIFEN;
HYSTERECTOMY

Background. Breast density is an important risk factor for breast cancer and is known to be associated with characteristics such as age, race, and hormone levels; however, it is unclear what factors contribute to changes in breast density in postmenopausal women over time. Understanding factors associated with density changes may enable a better understanding of breast cancer risk and facilitate potential strategies for prevention. Methods. This study investigated potential associations between personal factors and changes in mammographic density in a cohort of 3,392 postmenopausal women with no personal history of breast cancer between 2011 and 2017. Self-reported information on demographics, breast and reproductive history, and lifestyle factors, including body mass index (BMI), alcohol intake, smoking, and physical activity, was collected by an electronic intake form, and breast imaging reporting and database system (BI-RADS) mammographic density scores were obtained from electronic medical records. Factors associated with a longitudinal increase or decrease in mammographic density were identified using Fisher's exact test and multivariate conditional logistic regression. Results. 7.9% of women exhibited a longitudinal decrease in mammographic density, 6.7% exhibited an increase, and 85.4% exhibited no change. Longitudinal changes in mammographic density were correlated with age, race/ethnicity, and age at menopause in the univariate analysis. In the multivariate analysis, Asian women were more likely to exhibit a longitudinal increase in mammographic density and less likely to exhibit a decrease compared to White women. On the other hand, obese women were less likely to exhibit an increase and more likely to exhibit a decrease compared to normal weight women. Women who underwent menopause at age 55 years or older were less likely to exhibit a decrease in mammographic density compared to women who underwent menopause at a younger age. Besides obesity, lifestyle factors (alcohol intake, smoking, and physical activity) were not associated with longitudinal changes in mammographic density. Conclusions. The associations we observed between Asian race/obesity and longitudinal changes in BI-RADS density in postmenopausal women are paradoxical in that breast cancer risk is lower in Asian women and higher in obese women. However, the association between later age at menopause and a decreased likelihood of decreasing in BI-RADS density over time is consistent with later age at menopause being a risk factor for breast cancer and suggests a potential relationship between greater cumulative lifetime estrogen exposure and relative stability in breast density after menopause. Our findings support the complexity of the relationships between breast density, BMI,

hormone exposure, and breast cancer risk. [Park, Hannah Lui]

Profile of Plants from Sardinia (Italy), a Hotspot for
Biodiversity in the Mediterranean Basin PLANTS-BASEL
English Article Sardinian
plants; antitumor activity; cell cycle; apoptosis; NMR profiling;
sesquiterpene lactones BREAST-CANCER RISK; IDENTIFICATION;
ASTERACEAE; DISTRICT; WOMEN Sardinia (Italy), with its wide range
of habitats and high degree of endemism, is an important area for
plant-based drug discovery studies. In this work, the antitumor
activity of 35 samples from Sardinian plants was evaluated on
human osteosarcoma cells U2OS. The results showed that five plants
were strongly antiproliferative: *Arbutus unedo* (AuL), *Cynara*
cardunculus (CyaA), *Centaurea calcitrapa* (CcA), *Smilax aspera*
(SaA), and *Tanacetum audibertii* (TaA), the latter endemic to
Sardinia and Corsica. Thus, their ability to induce cell cycle
arrest and apoptosis was tested. All extracts determined cell
cycle block in G2/M phase. Nevertheless, the p53 expression levels
were increased only by TaA. The effector caspases were activated
mainly by CycA, TaA, and CcA, while AuL and SaA did not induce
apoptosis. The antiproliferative effects were also tested on human
umbilical vein endothelial cells (HUVEC). Except for AuL, all the
extracts were able to reduce significantly cell population,
suggesting a potential antiangiogenic activity. The phytochemical
composition was first explored by H-1 NMR profiling, followed by
further purifications to confirm the structure of the most
abundant metabolites, such as phenolic compounds and sesquiterpene
lactones, which might play a role in the measured bioactivity.

 Alfa, GK; Shamseddine, AI Charafeddine, Maya
 A.; Olson, Sara H.; Mukherji, Deborah; Temraz, Sally N.; Abou-
 Alfa, Ghassan K.; Shamseddine, Ali I. Proportion of
 cancer in a Middle eastern country attributable to established
 risk factors BMC CANCER English Article
 BODY-MASS INDEX; DOSE-RESPONSE
 METAANALYSIS; MEDITERRANEAN DIET; PHYSICAL-ACTIVITY; HELICOBACTER-
 PYLORI; BLADDER-CANCER; LUNG-CANCER; ASSOCIATION; POPULATION;
 ADHERENCE Background: Providing an estimate of the percentage of
 cancer in Lebanon by 2018 that is due to the exposure to risk
 factors in 2008. Factors include: smoking, body mass index (BMI),
 physical inactivity, dietary factors, alcohol consumption,
 infections, and air pollution in adults. Method: Population
 Attributable Fraction (PAF) was calculated using the proportion of
 the population exposed and relative risks for each risk factor
 from meta-analyses. The PAF estimates the proportion of cases in
 which exposure may have played a causal role. Results: Smoking
 caused most cancer cases, and it will further add a total of 1800
 new cases by 2018. Among many other cancers, lung cancer had the
 largest proportion attributable of around 75%. BMI is expected to
 increase colorectal, liver and gastric cardia carcinoma
 specifically in males. High physical activity has a an average of
 15% protection rate on cancer on colorectal cancer. Minimal
 adherence to Mediterranean diet will affect gastric cancer
 incidence by 7%. Cases of oropharyngeal and esophageal cancer will
 be the result of alcohol consumption mainly in males. H. Pylori
 infection is expected to result in half of the gastric cases by
 2018. The high exposure to air pollution is expected to contribute
 by 13% to lung cancer cases in 2018. Conclusion: The highest
 benefits can be achieved by controlling tobacco smoking.
 Interrelated and small changes in weight, physical activity and
 healthy diet with limited alcohol consumption can protect against
 several GI cancers in the long run. These results can be used to
 determine public health interventions that target important risk
 factors in the general population. [Charafeddine, Maya A.;

types 16 and 18 in healthy women with cytologically negative pap

smear in Iran INDIAN JOURNAL OF PATHOLOGY AND MICROBIOLOGY

English Article

Human papillomavirus; pap smear; type16 and 18 INVASIVE

CERVICAL-CANCER; GENITAL HUMAN-PAPILLOMAVIRUS; AGE-SPECIFIC

PREVALENCE; POOLED ANALYSIS; INFECTION; HPV; CLEARANCE; COHORT;

POPULATION; WORLDWIDE Background: Because human papillomavirus

(HPV) is one of the causal factors in cervical cancer,

understanding the epidemiology of this infection is an important

step towards developing strategies for prevention. Materials and

Methods: We evaluated the prevalence of high-risk human

papillomavirus Types 16 and 18 in cervical samples from 402

healthy women with normal Pap smears by testing with type-specific

primers in the polymerase chain reaction. Participants were seen

at two gynecological clinics affiliated to the Shiraz University

of Medical Sciences in Iran. Result: The prevalence of positive

HPV findings was 5.5%; high-risk HPV human papillomavirus Type 16

prevalence was 2% and no patient harbored HPV-18. The prevalence

of HPV was 4.5% in younger age group and gradually increased to

20% in the 4(th) decade. Conclusion: The prevalence of high-risk

HPV was highest in the youngest women and gradually decreased with

age. Overall, the prevalence of HPV in our population is low.

J Barrajon-Catalan, E; Fernández-Arroyo, S; Saura, D; Guillén, E; Fernández-Gutiérrez, A; Segura-Carretero, A; Micol, V

Barrajon-Catalan, Enrique; Fernandez-Arroyo, Salvador; Saura, Domingo; Guillen, Emilio; Fernandez-Gutierrez, Alberto; Segura-Carretero, Antonio; Micol, Vicente Cistaceae aqueous extracts containing ellagitannins show antioxidant and antimicrobial capacity, and cytotoxic activity against human cancer cells FOOD AND CHEMICAL TOXICOLOGY English

Article Cistus; HPLC-DAD-ESI-MS/MS; Antioxidant; Antimicrobial; Antitumor; Ellagitannins CISTUS-LADANIFER L; TOTAL PHENOLIC CONTENT; ROOPERI CORM EXTRACT; GALLIC ACID; IN-VITRO; PROTEIN PRECIPITATION; MEDICINAL-PLANTS; BREAST-CANCER; VOLATILE COMPOUNDS; POMEGRANATE JUICE

Roots and aerial parts of Cistaceae have been used since ancient times in the Mediterranean cultures for its medicinal properties. In this study, phenolic and tannin content of *C. ladanifer* and *C. populifolius* leaves aqueous extracts were determined and their antioxidant and antimicrobial activity were fully studied by several in vitro assays. Their major compounds were identified and quantitated by high-performance liquid chromatography with diode array detection coupled to electrospray ion-trap mass spectrometry. Cytotoxicity on a panel of human cancer cells was also determined. *C. populifolius* extract was stronger antioxidant than *C. ladanifer* extract in electron transfer reaction based assays but *C. ladanifer* extract was more effective to inhibit peroxy radicals. The major compounds in both extracts were ellagitannins, especially punicalagins derivatives, showing *C. populifolius* a higher content. *C. ladanifer* showed noteworthy antibacterial activity against *Staphylococcus aureus*, whereas *C. populifolius* was effective against *Escherichia coli*, with MICs values of 154 and 123 μ g/mL, respectively. Last, both extracts showed a notorious capacity to inhibit the proliferation of M220 pancreatic cancer cells and MCF7/HER2 and JIMT-1 breast cancer cells. The leaves of these plants suppose a source for water-soluble ellagitannins-enriched polyphenolic extracts with antioxidant and antimicrobial activities. Their cytotoxic activity against several cancer cells may deserve further attention. (C) 2010 Elsevier Ltd. All rights reserved. [Barrajon-Catalan,

J Chiumento, A; Hosny, W; Gaber, E; Emadeldin, M; El Barabry, W; Hamoda, HM; Alonge, O Chiumento, Anna; Hosny, Walaa; Gaber, Eman; Emadeldin, Maha; El Barabry, Walaa; Hamoda, Hesham M.; Alonge, Olakunle Exploring the acceptability of a WHO school-based mental health program in Egypt: A qualitative study SSM-MENTAL HEALTH
English Article Child and adolescent; Mental health; Psychosocial; School-based services; Qualitative; Implementation science; Theoretical framework of acceptability EASTERN MEDITERRANEAN REGION; OF-ONSET DISTRIBUTIONS; SELF-EFFICACY; LIFETIME PREVALENCE; LOW-INCOME; CARE; DISORDERS; SERVICES; YOUTH; INTERVENTIONS Mental health interventions should target critical developmental stages, such as childhood and adolescence; and be embedded into cross-sectoral settings including education. The World Health Organization, Eastern Mediterranean Regional office has developed a school-based mental health program (SMHP), encouraging implementation research to inform its scale-up. We contribute to this by exploring stakeholder acceptability of the SMHP as a key assumption underpinning successful program implementation. This qualitative study, conducted January to July 2019 in Al Obour, Egypt, explores stakeholder views of SMHP acceptability, the roles of teachers and school psychologists in supporting child mental health, and

barriers to SMHP implementation and scale-up. Focus group discussions (n = 4) and individual in-depth interviews (n = 7) were conducted with 30 stakeholders (parents, teachers, psychologists, and support centre managers). Data were analysed thematically against the theoretical framework of acceptability. Our results indicate that the SMHP is highly acceptable to teachers, psychologists, parents, and other education professionals. Key findings indicate the SMHP fits with teachers' and school psychologists' values, and highlight the importance of collaboration among these stakeholders for program effectiveness. Program features such as a community-based centre and respect for privacy and confidentiality are recognised to reduce parents' opportunity costs, and influence their affective attitudes, leading to increased engagement. Factors such as teacher burden require additional exploration and strategies to address them as potential impediments to successful SMHP implementation. This qualitative study yields important insights from multiple stakeholders into the acceptability of a school-based mental health intervention, providing support for scale-up of the SMHP in Egypt and the Region. EGF-SNX3-EGFR axis drives tumor progression and metastasis in triple-negative breast cancers ONCOGENE English Article

GROWTH-FACTOR RECEPTOR; UP-REGULATION; RETROGRADE TRANSPORT; DEGRADATION; RETROMER; EGFR; TRAFFICKING; EXPRESSION; INHIBITOR; EFFICACY Epidermal growth factor receptor (EGFR) has critical roles in epithelial cell physiology. Over-expression and over-activation of EGFR have been implicated in diverse cancers, including triple-negative breast cancers (TNBCs), prompting anti-EGFR therapies. Therefore, developing potent therapies and addressing the inevitable drug resistance mechanisms necessitates deciphering of EGFR related networks. Here, we describe Sorting Nexin 3 (SNX3), a member of the recycling retromer complex, as a critical player in the epidermal growth factor (EGF) stimulated EGFR network in TNBCs. We show that SNX3 is an immediate and sustained target of EGF stimulation initially at the protein level and later at the transcriptional level, causing increased SNX3 abundance. Using a proximity labeling approach, we observed increased interaction of SNX3 and EGFR upon EGF stimulation. We also detected colocalization of SNX3 with early endosomes and endocytosed EGF. Moreover, we show that EGFR protein levels are sensitive to SNX3 loss. Transient RNAi models of SNX3 downregulation have a temporary reduction in EGFR levels. In contrast, long-term silencing forces cells to recover and overexpress EGFR mRNA and protein, resulting in increased proliferation, colony formation, migration, invasion in TNBC cells, and increased tumor growth and metastasis in syngeneic models. Consistent with these results, low SNX3 and high EGFR mRNA levels correlate with poor relapse-free survival in breast cancer patients. Overall, our results suggest that SNX3 is a critical player in the EGFR network in TNBCs with implications for other cancers dependent on EGFR activity.

CAPACITY; ROSMARINIC ACID; ESSENTIAL OILS; NITRIC-OXIDE; PLANTS;
COLITIS Purpose: Little is known about the pharmacological
effects of the phenolic compounds of Pennyroyal (Mentha pulegium).
This Mediterranean aromatic plant, used as a gastronomic spice and
as food preservative by the food industry has been studied mainly
due to its essential oil antibacterial properties, composed
primarily by monoterpenes. With this work, we aimed to evaluate
the effects of a phenolic extract of pennyroyal in the impairment
of inflammatory processes in Inflammatory Bowel Diseases (IBD) and
in the potential inhibition of progression to colorectal cancer
(CRC). Methods: To that purpose, we evaluated the effect of
pennyroyal extract administration in a model of TNBS-induced

colitis in mice and further determined its effect on human colon carcinoma cell proliferation and invasion. Results: The phenolic extract of pennyroyal exhibited antioxidant properties in in vitro assays and administration of the extract in a rat model of carrageenan-induced paw oedema led to significant anti-inflammatory effects. Further results evidenced a beneficial effect of the phenolic extract in the attenuation of experimental colitis and a potential antiproliferative effect on cultured colon cancer cells, effects not previously described, to our knowledge. A reduction in several markers of colon inflammation was observed following administration of the extract to colitis-induced mice, including functional and histological indicators. A successful inhibition of cancer cell invasion and proliferation was also observed in in vitro studies with HT-29 cells. Furthermore, the extract also led to a reduced expression of iNOS/COX-2 in the colon of colitis-induced mice, both being crucial mediators of intestinal inflammation. Conclusions: Taking into consideration the central role of inflammation in the pathophysiology of CRC and the recognised connection between inflammatory events and cancer, these results enlighten the relevance of the phenolic constituents of pennyroyal as important pharmacological sources in the investigation of new treatment options for patients with inflammatory bowel diseases. Rahmani, Rami; Bouajila, Jalloul; Souchard, Jean
Pierre; Debouba, Mohamed Investigation of
Phytochemistry and Bioactivity of *Anabasis oropediorum* Maire
Leaves and Stem Organic Extracts CHEMISTRY AFRICA-A JOURNAL OF
THE TUNISIAN CHEMICAL SOCIETY English Article

Anabasis oropediorum;
Antioxidant; Chromatography; Bioactivity; PCA CYTOTOXIC
ACTIVITY; ANTIBACTERIAL *Anabasis oropediorum* is a spontaneous
chamaephyte growing in the arid regions of North Africa. The
present work focused on the evaluation of chemical composition
analysis and bioactivity of *A. oropediorum* organ extracts. Stems
and leaves powder were successively extracted with cyclohexane
(CYHA), dichloromethane (DCM), ethyl acetate (EtOAc) and methanol
(MeOH). GC-MS was used to identify the volatile compounds, while
the phenolic compounds were identified and quantified using HPLC-
DAD. The antioxidant capacity was evaluated as the DPPH free
radical scavenging capacity. In addition, the anti-
acetylcholinesterase (AChE) and anti-inflammatory activities (15-
LOX) were determined spectrophotometrically. Additionally, the
cytotoxicity of the extracts was evaluated against human colon
cancer (HCT-116) and human breast cancer (MCF-7) cell lines using
the MTT assay. The highest phenolic (253.3 mg GAE/g dr) and
flavonoids (19.3 mg QE/g dr) contents were recorded in stem
organic extracts. Furthermore, GC-MS analysis revealed the
presence of three classes of volatile compounds (phenolic acids,
flavonoids, and fatty alcohols) in the EtOAc extract. *A.*
oropediorum extracts showed different HPLC-DAD chromatogram
profiles depending on organic solvent polarity and plant organ.
Thus, among the identified molecules, 3',5'-dihydroxyflavone was
the major compound in leaves extracts (35.7 mg/g dr). However,
2,4-dihydroxy-3,6-dimethyl benzoic acid was most accumulated in
stem extracts (18.8 mg/g dr). The *A. oropediorum* stem extracts
exhibited better antioxidant, anti-AChE, and anti-15-LOX
activities, compared to leaves extracts ($p < 0.05$). However, the

leaves extracts showed stronger cytotoxicity against MCF-7 cell line, relative to stem ones. Principal component analysis (PCA) revealed that the chemical composition and the biological activities of *A. oropediorum* were modulated by plant tissue and solvent polarity. The Cytotoxic Effect of

Essential Oil of Syrian Citrus limon Peel on Human Colorectal

Carcinoma Cell Line (Lim1863) MIDDLE EAST JOURNAL OF CANCER

English Article

Citrus limon; Essential oils; Cytotoxicity; LIM1863

Background: Essential oils are the volatile fraction of aromatic and medicinal plants created after extraction by steam or water distillation. Species of the genus *Citrus* (Rutaceae) have been widely used in traditional medicine as volatile oils and are currently the subject of numerous research. Citrus essential oil consists of different terpenes that have antitumor activities. This study determines the cytotoxic effect of the essential oils of *Citrus limon* L. peels on a colorectal cancer cell line (LIM1863). Methods: We harvested four samples from four locations in Syria. Essential oils were prepared by hydrodistillation and analyzed by Gas chromatography- mass spectrometry (GC-MS). Various concentrations of essential oils (0.5-48 μ g/ml) were added to cultured cells and incubated for 72 h. Cell viability was evaluated by MTT-based cytotoxicity assay. Results: We noted 18 components that represented 98.81% of the total oil content. The major components were: limonene (61.8%-73.8%), gamma-terpinene (9.4%-10.4%), gamma-pinene (3.7%-6.9%), O-cymene (1%-2.4%), and citral (0.8%-5.4%). The obtained IC₅₀ value range of Citrus limon essential oils was 5.75-7.92 μ g/ml against LIM1863. Conclusion: This study revealed that Syrian Citrus limon essential oil has a cytotoxic effect on the human colorectal carcinoma cell line LIM1863 when studied in vitro. Stem cell-like
transcriptional reprogramming mediates metastatic resistance to
mTOR inhibition ONCOGENE English Article

BREAST-CANCER; MAMMARY STEM;
MESENCHYMAL TRANSITION; EMBRYONIC STEM; SELF-RENEWAL; EXPRESSION;
GENES; PATHWAY; TARGET; MOUSE Inhibitors of the mechanistic
target of rapamycin (mTOR) are currently used to treat advanced
metastatic breast cancer. However, whether an aggressive phenotype
is sustained through adaptation or resistance to mTOR inhibition
remains unknown. Here, complementary studies in human tumors,
cancer models and cell lines reveal transcriptional reprogramming
that supports metastasis in response to mTOR inhibition. This
cancer feature is driven by EVI1 and SOX9. EVI1 functionally
cooperates with and positively regulates SOX9, and promotes the
transcriptional upregulation of key mTOR pathway components (REHB
and RAPTOR) and of lung metastasis mediators (FSCN1 and SPARC).
The expression of EVI1 and SOX9 is associated with stem cell-like
and metastasis signatures, and their depletion impairs the
metastatic potential of breast cancer cells. These results
establish the mechanistic link between resistance to mTOR
inhibition and cancer metastatic potential, thus enhancing our
understanding of mTOR targeting failure. [Mateo, F.; Aguilar,

Citrus sinensis and Vitis vinifera Protect Cardiomyocytes
 from Doxorubicin-Induced Oxidative Stress: Evaluation of
 Onconutraceutical Potential of Vegetable Smoothies ANTIOXIDANTS

adjuvant therapy; anthracyclines; antioxidants; apoptosis; cardiotoxicity; functional foods; onconutraceutical; oxidative stress; polyphenols ANTIOXIDANT ACTIVITY; VAR. MARAVILLA; APOPTOSIS; CELLS; CARDIOTOXICITY; MECHANISMS; TOXICITY; L.; INTERVENTION; POLYPHENOL The interest towards nutraceuticals able to counteract drug side effects is continuously growing in current chemotherapeutic protocols. In the present study, we demonstrated that smoothies containing mixtures of *Citrus sinensis* and *Vitis vinifera* L. cv. Aglianico N, two typical fruits of the Mediterranean diet, possess bioactive polyphenols that protect cardiomyocytes against doxorubicin-induced oxidative stress. The polyphenolic extracts isolated from *Citrus sinensis*- and *Vitis vinifera*-based functional smoothies were deeply characterized by Liquid Chromatography-Mass Spectrometry methods. Subsequently, the functional smoothies and relative mixtures were tested to verify their ability to affect cellular viability and oxidative stress parameters in embryonic cardiomyocyte cells (H9c2), and human breast adenocarcinoma cell line (MCF-7) exposed to doxorubicin. Interestingly, we found that the mix resulting from *Citrus sinensis* and *Vitis vinifera* association in ratio 1:1 was able to reduce cardiomyocytes damage induced by anthracyclines, without significantly interfering with the pro-apoptotic activity of the drug on breast cancer cells. These results point out the potential use of vegetable smoothies as adjuvants functional foods for chemotherapeutic anticancer protocols. J Garduno-Diaz, SD; Husain, W; Ashkanani, F; Khokhar, S Garduno-Diaz, S. D.; Husain, W.; Ashkanani, F.; Khokhar, S. Meeting challenges related to the dietary assessment of ethnic minority populations JOURNAL OF HUMAN NUTRITION AND DIETETICS English Article

diet; ethnic foods; immigrant foods; nutrient; South Asian FOOD FREQUENCY QUESTIONNAIRE; SOUTH-ASIANS; PORTION SIZE; EDUCATION LEVEL; CHILDREN; HABITS; ACCULTURATION; PHOTOGRAPHS; RESIDENTS; WOMEN Background: Migrants from the Indian subcontinent comprise the largest minority group in the UK. With the process of migration come alterations in lifestyle and eating habits. The present study aimed to disseminate the valuable information, experiences and challenges faced by researchers who conduct studies with ethnic minority groups in the area of diet and nutritional surveys, with an emphasis on migrant South Asians. Methods: The findings reported are the result of research carried out during 2008-2012, involving 1100 face-to-face dietary recalls conducted in the UK among South Asian children (aged 1.5-11 years; n = 300) and adults (= 30 years; n = 100). Results: Factors to consider when planning and carrying out diet and nutrition survey studies among migrant South Asians were identified and include the employment of culture-specific tools, visual aid reinforcement and the involvement of key community members and translators to facilitate recruitment and data collection. One of the best practices found when working with minority groups was the use of incentives and tangible benefits to reward study participants. It was also found that constant communication and follow-up of the study participants improved the quality of the data and the likelihood of maintaining links with community members for future studies. Conclusions: From the results of in-house studies and a revision of practices reported in earlier literature, two 24-h face-to-face dietary recalls are recommended as the optimal method for the dietary assessment of migrant South Asians. To complement this assessment, ethnic-specific food frequency questionnaires such as that developed and successfully implemented among South Asians in the present study must be employed. Identification and expansion of human colon-cancer-initiating cells NATURE English Article

STEM-CELLS; CARCINOEMBRYONIC ANTIGEN; EXPRESSION; MUTATIONS; LEUKEMIA; TUMORS Colon carcinoma is the second most common cause of death from cancer(1). The isolation and characterization of tumorigenic colon cancer cells may help to devise novel diagnostic and therapeutic procedures. Although there is increasing evidence that a rare population of undifferentiated cells is responsible for tumour formation and maintenance(2-4), this has not been explored for colorectal cancer. Here, we show that tumorigenic cells in colon cancer are included in the high-density CD133(+) population, which accounts for about 2.5% of the tumour cells. Subcutaneous injection of colon cancer CD133(+) cells readily reproduced the original tumour in immunodeficient mice, whereas CD133(-) cells did not form tumours. Such tumours were serially transplanted for several generations, in each of which we observed progressively faster tumour growth without significant phenotypic alterations. Unlike CD133(-) cells, CD133(+) colon cancer cells grew exponentially for more than one year in vitro as undifferentiated tumour spheres in serum-free medium, maintaining the ability to engraft and reproduce the same morphological and antigenic pattern of the original tumour. We conclude that colorectal cancer is created and propagated by a small number of undifferentiated tumorigenic CD133(+) cells, which should therefore be the target of future therapies. HPV High-Risk Genotypes in Three Cohorts of Women in Ouagadougou (Burkina Faso) MEDITERRANEAN JOURNAL OF HEMATOLOGY AND INFECTIOUS DISEASES English Article

The development of cervical cancer is associated with high-risk Human papilloma viruses (HPVHR). In sub-Saharan Africa cervical cancer is the most common cancer among women and the leading cause of death attributed to malignant tumors. This study aims to identify HPV genotypes within the 30'S and 50'S HPV families found in two previous studies from our laboratory, and to determine the prevalence of twelve HPV-HR genotypes in a population of women in Ouagadougou. The twelve HPV-HR genotypes were determined by real-time multiplex PCR, in 180 samples from the general population and among a group of HIV-1 infected women. The most common genotypes found were HPV-35 (29.4%) and HPV-31 (26.1%) of the 30' S family, and HPV-52 (29.4%) and HPV-58 (20.6%) of the 50' S family. Multiple infections of HPV-HR were observed in 78.03% of infected women. The frequencies of HPV genotypes from the 30' S and 50' S families were higher, while the genotypes HPV-16 and 18 were lower among the women in our study.

PREDIMED Study Grp
Frequency of nut consumption and mortality risk in the
PREDIMED nutrition intervention trial BMC MEDICINE
English Article Cancer;
Cardiovascular; Mortality; Nuts; PREDIMED study CORONARY-HEART-DISEASE; MEDITERRANEAN DIET; CANCER-RISK; METABOLIC SYNDROME;
COLORECTAL-CANCER; HEALTH; WOMEN; QUESTIONNAIRE; PREVENTION; DEATH

Background: Prospective studies in non-Mediterranean populations have consistently related increasing nut consumption to lower coronary heart disease mortality. A small protective effect on all-cause and cancer mortality has also been suggested. To examine the association between frequency of nut consumption and mortality in individuals at high cardiovascular risk from Spain, a Mediterranean country with a relatively high average nut intake per person. Methods: We evaluated 7,216 men and women aged 55 to 80 years randomized to 1 of 3 interventions (Mediterranean diets supplemented with nuts or olive oil and control diet) in the PREDIMED ('PREvencion con DIeta MEDiterranea') study. Nut consumption was assessed at baseline and mortality was ascertained by medical records and linkage to the National Death Index. Multivariable-adjusted Cox regression and multivariable analyses with generalized estimating equation models were used to assess the association between yearly repeated measurements of nut consumption and mortality. Results: During a median follow-up of 4.8 years, 323 total deaths, 81 cardiovascular deaths and 130 cancer deaths occurred. Nut consumption was associated with a significantly reduced risk of all-cause mortality (P for trend < 0.05, all). Compared to non-consumers, subjects consuming nuts > 3

servings/week (32% of the cohort) had a 39% lower mortality risk (hazard ratio (HR) 0.61; 95% CI 0.45 to 0.83). A similar protective effect against cardiovascular and cancer mortality was observed. Participants allocated to the Mediterranean diet with nuts group who consumed nuts > 3 servings/week at baseline had the lowest total mortality risk (HR 0.37; 95% CI 0.22 to 0.66).

Conclusions: Increased frequency of nut consumption was associated with a significantly reduced risk of mortality in a Mediterranean population at high cardiovascular risk. J Weikart, D; Lin, D; Dhingra, R; Al-Shaar, L; Sturgeon, K Weikart, Daphne; Lin, Dan; Dhingra, Radha; Al-Shaar, Laila; Sturgeon, Kathleen Pre-Diagnosis Diet and Physical Activity and Risk of Cardiovascular Disease Mortality among Female Cancer Survivors CANCERS English Article Alternative Mediterranean Diet; metabolic equivalent task; retrospective cohort study; neoplasm; California Teachers Study BREAST-CANCER; CALIFORNIA TEACHERS; WOMEN; PATTERNS; RECURRENCE; EXERCISE; QUALITY; RATES; DEATH; FAT Simple Summary The number of cancer survivors is increasing; however, cancer survivors are at an increased risk of cardiovascular diseases (CVD) and CVD mortality. Therefore, it is pertinent to understand how lifestyle choices such as dietary patterns and physical activity are associated with this risk. Little is known about the relationship of pre-cancer diagnosis diet quality and physical activity (PA) with CVD among cancer survivors. Most studies have focused on post-cancer diagnosis risk factors, without accounting for their status in the pre-diagnosis period or interaction on CVD mortality. We examined pre-cancer diagnosis diet quality and physical activity in relation with CVD mortality risk in female cancer survivors from the California Teachers Study cohort. We hypothesized that higher diet quality scores and higher physical activity levels prior to cancer diagnosis would be associated with lower risk of CVD mortality in female cancer survivors. Sub-optimal diet and physical activity (PA) levels have been associated with increased risk of cardiovascular disease (CVD) mortality. The relationship between pre-cancer diagnosis diet quality and PA level on CVD mortality risk in cancer survivors is unclear. We examined the association between pre-cancer diagnosis diet quality and leisure-time PA and their interaction on CVD mortality in cancer survivors. Diet quality was characterized by the Alternative Mediterranean Diet Index (aMED). Leisure-time PA was converted to a metabolic equivalent of task hours per week (MET-h/wk). During a median of 6.3 years of follow-up of 18,533 female cancer survivors, we identified 915 CVD deaths. aMED score was not associated with CVD mortality. PA level was inversely associated with CVD mortality (HRQ1-Q4 = 0.74; 95% CI: 0.61-0.88; P-trend = 0.0014). Compared to cancer survivors with the lowest pre-diagnosis aMED score and PA level, cancer survivors with higher aMED scores and higher MET-hrs/wk were at a 33% lower risk of CVD mortality (HR = 0.67; 95% CI: 0.52-0.87). Overall, this study shows PA to be a strong predictor of CVD mortality in female cancer survivors. Our observations support the importance of PA throughout the lifecycle in lowering CVD mortality risk. J Erdem, M; Yalcin, S; Gunduz, U Erdem,
 M.; Yalcin, S.; Gunduz, U. Folic acid-conjugated
 polyethylene glycol-coated magnetic nanoparticles for doxorubicin
 delivery in cancer chemotherapy: Preparation, characterization and
 cytotoxicity on HeLa cell line HUMAN & EXPERIMENTAL TOXICOLOGY
 English Article

Cancer; HeLa cell; magnetic nanoparticles; cytotoxicity
 IRON-OXIDE NANOPARTICLES; DRUG-DELIVERY; FOLATE RECEPTOR;
 BREAST-CANCER; SYSTEM; MRI; TUMORS; PH Conventional chemotherapy
 is the most valid method to cope with cancer; however, it has
 serious drawbacks such as decrease in production of blood cells or
 inflammation of the lining of the digestive tract. These side
 effects occur since generally the drugs used in chemotherapy are
 distributed evenly within the body of the patient and cannot
 distinguish the cancer cells from the healthy ones. In this study,
 folic acid (FA)-conjugated, polyethylene-coated magnetic
 nanoparticles (FA-MNPs), and doxorubicin (Dox)-loaded formulation
 (Dox-FA-MNPs) were prepared. The cytotoxicity of these
 nanoparticles on HeLa and Dox-resistant HeLa cells was
 investigated. Magnetic nanoparticles (MNPs), polyethylene glycol
 (PEG)-coated MNPs (PEG-MNPs), and FA-MNPs were successfully
 synthesized and characterized by several methods. Dox loading of
 FA-MNPs and release profile of Dox from the nanoparticles were
 studied. Cytotoxic effects of FA-MNPs and Dox-FA-MNPs on HeLa
 cells were analyzed. MNPs, PEG-MNPs, and FA-MNPs all had small
 sizes and supermagnetic behavior. High amounts of Dox could be
 loaded onto the nanoparticles (290 $\mu\text{g mL}^{-1}$). In 24 h, 15.7% of Dox
 was released from the Dox-FA-MNPs. The release was increased in
 acidic conditions (pH 4.1). Internalization studies showed that
 FA-MNPs and Dox-FA-MNPs were taken up efficiently by HeLa cells.

The investigation of cytotoxicity of the particles indicated that 38-500 μmL^{-1} Dox-FA-MNPs significantly decreased the proliferation of HeLa cells compared to FA-MNPs. Due to their size, magnetic properties, internalization, drug release, and cytotoxicity characteristics, the MNPs prepared in this study may have potential application as a drug delivery system in cancer chemotherapy. Sarhan, Adnan Lutfi; Modallal, Shadenaz; Mahamid, Fayed Azez; Berte, Denise Ziya Depression symptoms and associated factors among thalassemia patients in the Palestinian Territories: a cross-sectional study MIDDLE EAST CURRENT PSYCHIATRY-MECPSYCH English Article

Thalassemia; Depression; Palestine
QUALITY-OF-LIFE; INVENTORY-II; ANXIETY; CHILDREN

Background Thalassemia is a condition that causes the human body to destroy red blood cells faster than they can be made. It causes physical symptomology as well as psychological distress. The current study aimed to identify the prevalence of depression symptoms among individuals with moderate to severe thalassemia. A quantitative descriptive cross-sectional design was applied utilizing the Beck Depression Inventory to assess the level of depression in the sample. Results Some significant relationships were demonstrated in the sample: males reporting severe depression symptoms than females by 6.0 times (95% CI 0.07-0.62, p 0.014), and reporting moderate depression symptoms (95% CI 0.00-0.47, p 0.05). Additionally, income was found to be a predictor of level of depression symptoms with low income reported higher incidence of severe depression symptoms than those whose monthly income was > 400\$ by 18.4 times (95% CI 0.38-1.03, p <= 0.001), but not reporting a significant association between moderate depressive symptoms and monthly income (95% CI - 0.12-1.47, P 0.225). A significant association was found between the educational attainment and level of depression symptoms with lower levels of education predicting higher levels of severe depression symptoms (95% CI 0.069-0.89, p 0.022), but no significant association was

reported between moderate depression symptoms and educational attainment (95% CI - 0.49-0.01, p 0.81). Related to disease characteristics a relationship was confirmed between severe depressive symptoms and medication level such as the individual needing tablets or pumps (95% CI 0.189-1.05, p 0.005 and 95% CI 0.52-1.44, p 0.001) respectively. Other disease related variables showed no significant correlation with depressive symptom levels. Additional significant relationships were found in environment whereas increased moderate depressive symptoms were experienced by individuals residing in rural areas as opposed to those living in IDP camps or cities by 4 times (95% CI - 0.30-0.01, p 0.04), but no significant association was found between severe depression and the place of residence. The other independent variables had no significant correlation with severe or moderate depressive symptoms. Conclusion In light of these findings addressing symptoms of depression directly and supporting patients with thalassemia with basic life needs unrelated to their disease maybe mitigating depressive symptoms which may negatively affect recovery. Heather Healthy Dietary Patterns and Oxidative Stress as Measured by Fluorescent Oxidation Products in Nurses' Health Study NUTRIENTS English Article

healthy eating pattern; oxidative stress; fluorescent oxidation products; nutrition; epidemiology LIPID-PEROXIDATION PRODUCTS; CORONARY-HEART-DISEASE; BREAST-CANCER; FREE-RADICALS; MEDITERRANEAN-STYLE; ANTIOXIDANT STATUS; QUALITY SCORES; BLOOD-PRESSURE; DNA-DAMAGE; LIFE-STYLE Healthy diets may lower oxidative stress and risk of chronic diseases. However, no previous studies examined associations between diet and fluorescent oxidation products (FLOP), a global marker of oxidative stress. We evaluated

associations between healthy eating patterns (Alternative Healthy Eating Index (AHEI), Dietary Approach to Stop Hypertension (DASH), and Alternate Mediterranean Diet (aMED)) and FLOP, measured at three excitation/emission wavelengths (FLOP_360, FLOP_320, FLOP_400) from 2021 blood samples collected from 1688 women within the Nurses' Health Study. AHEI, DASH, and aMED scores were significantly positively associated with FLOP_360 and FLOP_320 concentrations (p-trend 0.04), but not associated with FLOP_400. Among specific food groups that contribute to these diet scores, significantly positive associations were observed with legumes and vegetables for FLOP_360, vegetables and fruits for FLOP_320, and legumes and alcohol for FLOP_400. Inverse associations were observed with nuts, sweets or desserts, and olive oil for FLOP_360, nuts for FLOP_320 and sweets or desserts for FLOP_400 (all p-trend 0.05). However, FLOP variation due to diet was small compared to overall FLOP variation. In conclusion, AHEI, DASH, and aMED scores were unexpectedly positively, but weakly, associated with FLOP_360 and FLOP_320. However, these findings should be interpreted cautiously as the determinants of FLOP concentrations are not fully understood. Antiproliferative Effects of Different Concentrations
of Auraptene on MCF7 Cancer Cell Line MIDDLE EAST JOURNAL OF
CANCER English Article

Auraptene; Apoptosis; Cytotoxicity; Cancer; MCF7
cells; MTT CITRUS AURAPTENE; APOPTOSIS; PROLIFERATION;
SUPPRESSION; METABOLISM; INHIBITORS; ACTIVATORS; PATHWAYS; AGENTS

Background: Auraptene is a coumarin derivative extracted from citrus species, such as lemon, grapefruit, and orange. To date, auraptene has shown antioxidant, antibacterial, anti-inflammatory, antiproliferative, antiapoptotic, and antitumor activities. Among these, antitumor activity has become more important over the recent years, while its underlying mechanism is not fully understood. The current study was conducted to evaluate the antiproliferative effect of auraptene and its mechanisms on MCF7 cell line. Method: This experimental study investigated whether hesperidin affected the proliferation of MCF-7 human breast cancer cells. MCF7 cells were cultured in DMEM medium with 10% fetal bovine serum, 100 µg/ml streptomycin, and 100 units/ml penicillin. The cells were incubated in order to be treated with different concentrations of auraptene and time points. Subsequently, the amount of cytotoxicity and apoptosis was measured utilizing MTT and PI staining. Results: The MTT assay revealed that auraptene had a significant effect on cell viability and induced apoptosis in MCF7 cells at concentrations of 75, 100, 130, 170, and 200 µM. Conclusion: In this study, through the induction of apoptosis, auraptene prevented the growth and inhibited the proliferation of MCF7 cells at high concentrations in a dose-dependent manner. However, further investigation is needed to reveal the mechanisms of auraptene concerning apoptosis induction. English Article HDGC; CDH1-negative case; lynch syndrome II; genetic screening; target gene sequencing; DNA repair genes; MSH2NONPOLYPOSIS COLORECTAL-CANCER; DNA-MISMATCH-REPAIR; SUSCEPTIBILITY GENE-MUTATIONS; GERMLINE MUTATIONS; CONSANGUINEOUS MARRIAGES; ENDOMETRIAL CANCER; 1ST DESCRIPTION; RISK; CARRIERS; MLH1 Several syndromic forms of digestive cancers are known to predispose to early-onset gastric tumors such as Hereditary Diffuse Gastric Cancer (HDGC) and Lynch Syndrome (LS). LSII is an extracolonic cancer syndrome characterized by a tumor spectrum including gastric cancer (GC). In the current work, our main aim was to identify the mutational spectrum underlying the genetic predisposition to diffuse gastric tumors occurring in a Tunisian family suspected of both HDGC and LS II syndromes. We selected the index case "JI-021", which was a woman diagnosed with a Diffuse Gastric Carcinoma and fulfilling the international guidelines for both HDGC and LSII syndromes. For DNA repair, a custom panel targeting 87 candidate genes recovering the four DNA repair pathways was used. Structural bioinformatics analysis was conducted to predict the effect of the revealed variants on the functional properties of the proteins. DNA repair genes panel screening identified two variants: a rare MSH2 c.728G>A classified as a variant with uncertain significance (VUS) and a novel FANCD2 variant c.1879G>T. The structural prediction model of the MSH2 variant and electrostatic potential calculation showed for the first time that MSH2 c.728G>A is likely pathogenic and is involved in the MSH2-MLH1 complex stability. It appears to affect the MSH2-MLH1 complex as well as DNA-complex stability. The c.1879G>T FANCD2 variant was predicted to destabilize the protein structure. Our results showed that the MSH2 p.R243Q variant is likely pathogenic and is involved in the MSH2-MLH1 complex stability, and molecular modeling analysis highlights a putative

impact on the binding with MLH1 by disrupting the electrostatic potential, suggesting the revision of its status from VUS to likely pathogenic. This variant seems to be a shared variant in the Mediterranean region. These findings emphasize the importance of testing DNA repair genes for patients diagnosed with diffuse GC with suspicion of LSII and colorectal cancer allowing better clinical surveillance for more personalized medicine. J Collins, AR; Gedik, CM; Olmedilla, B; Southon, S; Bellizzi, M Collins, AR; Gedik, CM; Olmedilla, B; Southon, S; Bellizzi, M Oxidative DNA damage measured in human lymphocytes: large differences between sexes and between countries, and correlations with heart disease mortality rates FASEB JOURNAL English Article

molecular epidemiology; oxidative DNA damage; coronary heart disease; cancer The 'antioxidant hypothesis' proposes that vitamin C, vitamin E, carotenoids, and other antioxidants occurring in fruit and vegetables afford protection against heart disease and cancer by preventing oxidative damage to lipids and to DNA, respectively. To test elements of this hypothesis, we have measured blood levels of dietary antioxidants, and 8-oxodeoxyguanosine (8-oxo-dG) concentrations in lymphocyte DNA, in healthy men and women from five European countries: France, Ireland, The Netherlands, Spain, and the U.K. Volunteers, aged 25-45, all nonsmokers, gave blood samples before and after a 12-wk carotenoid supplementation regime. Vitamin C was measured in plasma and vitamin E and carotenoids were measured in serum by high-performance liquid chromatography (HPLC). 8-oxo-dG was assayed by HPLC (with coulometric detection) in DNA isolated from lymphocytes from the same blood samples. Mean values were calculated for groups of volunteers at each sampling time according to country, sex, and supplementation (between 9 and 24 individual samples contributing to each mean). We found that 8-oxo-dG levels in lymphocyte DNA vary significantly according to sex and country. A low mean 8-oxo-dG concentration is seen in DNA of women from all five countries, and of men from France and Spain. 8-oxo-dG is significantly higher (up to about threefold) in lymphocyte DNA from men in Ireland and the U.K. Oxidative DNA damage is not significantly affected by carotenoid supplementation; nor is there any association with mean baseline levels of antioxidants, which are generally similar in the five countries. The five countries sampled lie on an axis from northern to southern Europe with a steep gradient: in terms of premature heart disease. There is a strong association between premature coronary heart disease mortality in men and the mean levels of 8-oxo-dG for the five countries ($r = 0.95$, $P < 0.01$). Women have low coronary heart disease mortality rates, which do not correlate with 8-oxo-dG. In terms of cancer deaths, only colorectal cancer in men shows a significant positive correlation ($r = 0.91$, $P < 0.05$), and stomach cancer in women is negatively correlated with DNA oxidation ($r = -0.92$, $P = 0.01$). TRITERPENOID; ANTIBACTERIAL ACTIVITY; ANTIMICROBIAL ACTIVITY;

BRONCHITIS VIRUS; CEDRUS-LIBANI; ALPHA-PINENE; LIMONENE;

CONSTITUENTS *Abies* is an important genus of the family

Pinaceae, with about 50 species found in the highlands of Asia, Europe, North Africa, and North and Central America. The principal aim of the present work was to investigate the chemical content and biological potential of the resin and cone from *Abies nordmanniana* subsp. *bornmulleriana* and *Abies nordmanniana* subsp. *equi-trojani*, respectively. The flavonoid and phenolic contents of the resin and cones were evaluated using liquid chromatography-high resolution mass spectrometry (LC-HRMS). Additionally, the essential oil and fatty acid compositions were analyzed using gas chromatography-mass spectrometry (GC-MS) and gas chromatography-flame ionization detector (GC-FID), respectively. Cytotoxicity of the extracts and essential oils were screened against certain cancer cell lines, namely, human prostate adenocarcinoma cell line (PC3), human lung adenocarcinoma cell line (A549), human pancreatic cancer cell line (PANC-1), human hepatocellular carcinoma cell line (HepG2), human breast cancer cell line (MDA-MB231), and normal human lung fibroblast cell line (CCD-34-LU), with MTT [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide] assay. According to the MTT results, hexane extracts of both cone (CH) and resin (RH), ethanol-water (CEW), dichloromethane (CD), and acetone (CA) extracts of the cone mostly inflict cytotoxicity in HepG2 cell line. Antiviral activities of *Abies nordmanniana* subsp. extracts at doses of 5 μ g/g and 10 μ g/g were also evaluated in ovo for their virucidal activity against avian coronavirus. *Abies nordmanniana* subsp. extracts

exhibited concentration -dependent antiviral activity on specific pathogen -free embryonated chicken eggs. Significantly, cone acetone extract (CA), cone ethanol extract (CE), and cone dichloromethane extract (CD) of *Abies nordmanniana* subsp. exhibited strong inhibition of the virus at a concentration of 10 μ g/g. The most potent virucidal activity was observed with ethanol -water extract of conifer form (CEW). According to these results, it was proved that *Abies nordmanniana* species could be a potential, sustainable, and renewable drug source, especially considering the impressive antiviral and significant cytotoxic activity potentials. USP32 is an active, membrane-bound ubiquitin protease overexpressed in breast cancers MAMMALIAN GENOME English Article

HIGH-LEVEL AMPLIFICATION; COPY NUMBER ALTERATIONS; DEUBIQUITINATING ENZYME; EXPRESSION; 17Q23; GENES; GOLGI; LOCALIZATION; ONCOGENES; PROTEINS USP32, on chromosomal band 17q23.1-17q23.2, is a highly conserved but uncharacterized gene that gave rise during evolution to a well-known hominoid-specific proto-oncogene, USP6. We investigated the expression profile of USP32 in human tissues and examined its functions to gain insight into this novel member of the well-conserved ubiquitination system. We detected ubiquitous USP32 expression across tissues and confirmed the predicted deubiquitination function owing to the presence of conserved peptidase signature asparagine, cysteine, histidine, and aspartic acid domains of ubiquitin-specific proteases. A Golgi localization of GFP-fused USP32 was detected by fluorescent protection assay and BODIPY-TR staining. In addition, stable silencing of USP32 caused a significant decrease in the proliferation and migration rate of cells. Based on these and the fact that USP32 maps to 17q23, which is commonly amplified in breast cancers, we analyzed USP32 expression in breast cancer cells. We detected high expression of USP32 in 50% (9 of 18) of breast cancer cell lines and 22% (9 of

41) of primary breast tumors compared to mammary epithelial cells. In summary, we report the preliminary characterization of this novel deubiquitinating enzyme on 17q23 and demonstrate its functional role in the ubiquitin system and its potential involvement in tumorigenesis. Targeting Colon Luminal Lipid Peroxidation Limits Colon Carcinogenesis Associated with Red Meat Consumption CANCER PREVENTION RESEARCH English Article
MUCIN-DEPLETED FOCI; COLORECTAL-CANCER; HEME-IRON; MEDITERRANEAN DIET; BEEF MEAT; RISK;

BIOMARKERS; RATS; NUTRITION; DIMETHYLHYDRAZINE Red meat is probably carcinogenic to humans (WHO/ IARC class 2A), in part through heme iron-induced lipoperoxidation. Here, we investigated whether red meat promotes carcinogenesis in rodents and modulates associated biomarkers in volunteers, speculating that an antioxidant marinade could suppress these effects via limitation of the heme induced lipid peroxidation. We gave marinated or non-marinated beef with various degrees of cooking to azoxymethane-initiated rats, Min mice, and human volunteers (crossover study). Mucin-depleted foci were scored in rats, adenoma in MM mice. Biomarkers of lipoperoxidation were measured in the feces and urine of rats, mice, and volunteers. The organoleptic properties of marinated meat were tested. Fresh beef increased colon carcinogenesis and lipoperoxidation in rats and mice and lipoperoxidation in humans. Without an adverse organoleptic effect on meat, marinade normalized peroxidation biomarkers in rat and mouse feces, reduced peroxidation in human feces and reduced the number of Mucin-depleted foci in rats and adenoma in female MM mice. This could lead to protective strategies to decrease the colorectal cancer burden associated with red meat consumption. (C) 2018 AACR. [Martin, Oceane C. Extravirgin olive oil up-regulates CB1 tumor suppressor gene in human colon cancer cells and in rat colon via epigenetic mechanisms JOURNAL OF NUTRITIONAL BIOCHEMISTRY

English Article

Endocannabinoid system; Bioactive lipids; Colon; Epigenetics; Olive oil; Phenolic compounds; Hydroxytyrosol
MONOUNSATURATED FATTY-ACIDS; DNA METHYLATION;

ENDOCANNABINOID SYSTEM; COLORECTAL-CANCER; HYDROXYTYROSOL; PREVENTION; EPIGENOME; CHEMOPREVENTION; CANNABINOID; ANANDAMIDE

Extravirgin olive oil (EVOO) represents the typical lipid source of the Mediterranean diet, an eating habit pattern that has been associated with a significant reduction of cancer risk. Diet is the more studied environmental factor in epigenetics, and many evidences suggest dysregulation of epigenetic pathways in cancer. The aim of our study was to investigate the effects of EVOO and its phenolic compounds on endocannabinoid system (ECS) gene expression via epigenetic regulation in both human colon cancer cells (Caco-2) and rats exposed to short- and long-term dietary EVOO. We observed a selective and transient up-regulation of CNR1 gene - encoding for type 1 cannabinoid receptor (CB1) - that was evoked by exposure of Caco-2 cells to EVOO (100 ppm), its phenolic extracts COPE, 50 μ M) or authentic hydroxytyrosol (HT, 50 μ M) for 24 h. None of the other major elements of the ECS (i.e., CB2; GPR55 and TRPV1 receptors; and NAPE-PLD, DAGL, FAAH and MAGL enzymes) was affected at any time point. The stimulatory effect of OPE and HT on CB, expression was inversely correlated to DNA methylation at CNR1 promoter and was associated with reduced proliferation of Caco-2 cells. Interestingly, CNR1 gene was less expressed in Caco-2 cells when compared to normal colon mucosa cells, and again this effect was associated with higher level of DNA methylation at CNR1. Moreover, in agreement with the in vitro studies, we also observed a remarkable (similar to 4-fold) and selective increase in CB1 expression in the colon of rats receiving dietary EVOO supplementation for 10 days. Consistently,

CpG methylation of rat Cnr1 promoter, miR23a and miR-301a, previously shown to be involved in the pathogenesis of colorectal cancer and predicted to target CB1 mRNA, was reduced after EVOO administration down to similar to 50% of controls. Taken together, our findings demonstrating CB1 gene expression modulation by EVOO or its phenolic compounds via epigenetic mechanism, both in vitro and in vivo, may provide a new therapeutic avenue for treatment and/or prevention of colon cancer. Bovine leukemia virus discovered in human blood

BMC INFECTIOUS DISEASES

English Article

Bovine leukemia virus; Human

blood; Zoonotic infection DNA; ANTIBODIES; SELECTION; SEQUENCE; CANCER; CELLS Background Bovine leukemia virus (BLV) infection is widespread in cattle globally and is present in marketed beef and dairy products. Human infection with BLV has been reported in breast and lung cancer tissues and was significantly associated with breast cancer in 3 case-control studies. The purpose of this current research was to determine if BLV is present in human blood cells and if antibodies to BLV are related to blood cell infection. Methods Standard liquid PCR and Sanger DNA sequencing were used to test for BLV in buffy coat cells (leukocytes and platelets) of blood specimens from 95 self-selected female subjects. Enzyme-linked immunosorbent assay (ELISA) for IgG, IgM, and IgA was used to detect antibodies to BLV in the plasma of the corresponding blood samples. Results BLV DNA was detected in the buffy coat cells of blood in 33/95 (38%) of the subjects by PCR and DNA sequencing. IgG antibodies were detected in 30/95 (32%), IgM in 55/95 (58%), and IgA in 30/95 (32%) of the subjects. There was no significant correlation between presence of the antibodies and presence of BLV DNA. Conclusions This first report of BLV in human blood raises the question of whether infection of leukocytes could conceivably lead to leukemia as it does in infected cattle. Also, system wide circulation of infected blood cells could facilitate BLV transit to various internal tissues/organs with potential for their infection and subsequent development of cancer. The most likely route of BLV transmission to humans would be zoonotic, as a foodborne infection. Although eradicated from cattle in some countries, BLV still has a high rate of infection in the Americas, the Middle East, and parts of Europe and Asia. This report of BLV in the blood layer containing human leukocytes/platelets adds important information which could be useful to elucidate possible routes of transmission of BLV to humans and to prevent further human infection. Vegetarian Dietary Patterns and the Risk of
Colorectal Cancers JAMA INTERNAL MEDICINE English

Article GROWTH-FACTOR-
I; ADVENTIST HEALTH; MEDITERRANEAN DIET; WHITE SUBJECTS; GLYCEMIC
LOAD; MISSING DATA; EPIC-OXFORD; MEAT-EATERS; BODY-WEIGHT;
CONSUMPTION IMPORTANCE Colorectal cancers are a leading cause of
cancer mortality, and their primary prevention by diet is highly
desirable. The relationship of vegetarian dietary patterns to
colorectal cancer risk is not well established. OBJECTIVE To
evaluate the association between vegetarian dietary patterns and
incident colorectal cancers. DESIGN, SETTING, AND PARTICIPANTS The
Adventist Health Study 2 (AHS-2) is a large, prospective, North
American cohort trial including 96 354 Seventh-Day Adventist men
and women recruited between January 1, 2002, and December 31,
2007. Follow-up varied by state and was indicated by the cancer
registry linkage dates. Of these participants, an analytic sample
of 77 659 remained after exclusions. Analysis was conducted using
Cox proportional hazards regression, controlling for important
demographic and lifestyle confounders. The analysis was conducted
between June 1, 2014, and October 20, 2014. EXPOSURES Diet was
assessed at baseline by a validated quantitative food frequency
questionnaire and categorized into 4 vegetarian dietary patterns
(vegan, lacto-ovo vegetarian, pescovegetarian, and semivegetarian)
and a nonvegetarian dietary pattern. MAIN OUTCOMES AND MEASURES
The relationship between dietary patterns and incident cancers of
the colon and rectum; colorectal cancer cases were identified
primarily by state cancer registry linkages. RESULTS During a mean
follow-up of 7.3 years, 380 cases of colon cancer and 110 cases of
rectal cancer were documented. The adjusted hazard ratios (HRs) in
all vegetarians combined vs nonvegetarians were 0.78 (95% CI,
0.64-0.95) for all colorectal cancers, 0.81 (95% CI, 0.65-1.00)
for colon cancer, and 0.71 (95% CI, 0.47-1.06) for rectal cancer.
The adjusted HR for colorectal cancer in vegans was 0.84 (95% CI,
0.59-1.19); in lacto-ovo vegetarians, 0.82 (95% CI, 0.65-1.02); in
pescovegetarians, 0.57 (95% CI, 0.40-0.82); and in
semivegetarians, 0.92 (95% CI, 0.62-1.37) compared with
nonvegetarians. Effect estimates were similar for men and women
and for black and nonblack individuals. CONCLUSIONS AND RELEVANCE
Vegetarian diets are associated with an overall lower incidence of
colorectal cancers. Pescovegetarians in particular have a much

lower risk compared with nonvegetarians. If such associations are causal, they may be important for primary prevention of colorectal cancers. phthalate exposure among postmenopausal women of the Women's Health Initiative ENVIRONMENTAL RESEARCH English
Article Phthalate; DASH;

aMed; DII; Biomarkers; Diet BISPHEENOL-A; INFLAMMATORY INDEX; MEDITERRANEAN DIET; DASH DIET; BEVERAGES; MORTALITY; DISEASE; SCORES; TRIAL; RISK Background: Phthalates are endocrine-disrupting chemicals linked to a higher risk of numerous chronic health outcomes. Diet is a primary source of exposure, but prior studies exploring associations between dietary patterns and phthalate exposure are limited. Objectives: We evaluated the associations between dietary patterns and urinary phthalate biomarkers among a subset of postmenopausal women participating in the Women's Health Initiative (WHI). Methods: We included WHI participants selected for a nested case-control study of phthalates and breast cancer (N = 1240). Dietary intake was measured via self-administered food frequency questionnaires at baseline and year-3. We used these data to calculate scores for alignment with the Dietary Approach to Stop Hypertension (DASH), alternative Mediterranean (aMed), and Dietary Inflammatory Index (DII) diets. We measured 13 phthalate metabolites and creatinine

in 2-3 urine samples per participant collected over 3-years when all participants were cancer-free. We fit multivariable generalized estimating equation models to estimate the crosssectional associations. Results: DASH and aMed dietary scores were inversely associated with the sum of di(2-Ethylhexyl) phthalate (-6.48%, 95% CI -9.84, -3.00; -5.23%, 95% CI -8.73, -1.60) and DII score was positively associated (9.00%, 95% CI 5.04, 13.11). DASH and aMed scores were also inversely associated with mono benzyl phthalate and mono-3-carboxypropyl phthalate. DII scores were positively associated with mono benzyl phthalate and the sum of di-n-butyl phthalate. Discussion: Higher dietary alignment with DASH and aMed dietary patterns were significantly associated with lower concentrations of certain phthalate biomarkers, while an inflammatory diet pattern was associated with higher phthalate biomarker concentrations. These findings suggest that dietary patterns high in fruits, vegetables, and low-fat foods and low in processed foods may be useful in avoiding exposure to phthalates.

Investigating the efficacy and feasibility of
using a whole-of-diet approach to lower circulating levels of C-
reactive protein in postmenopausal women: a mixed methods pilot
study MENOPAUSE-THE JOURNAL OF THE MENOPAUSE SOCIETY

English Article; Proceedings Paper Annual Scientific
Meeting of the Nutrition-Society-of-Australia DEC, 2021

ELECTR NETWORK Cardiovascular disease; Diet;
Inflammation; Obesity; Postmenopausal CARDIOVASCULAR-DISEASE
PREVENTION; EVIDENCE-BASED GUIDELINES; NUTRITION EDUCATION;
BEHAVIOR-CHANGE; MEDITERRANEAN DIET; METABOLIC SYNDROME; PHYSICAL-
ACTIVITY; WEIGHT REGAIN; OBESE ADULTS; OLDER-ADULTS

ObjectiveChronic inflammation is associated with obesity and
is an underlying pathophysiology for cardiovascular disease (CVD)
development in postmenopausal women. This study aims to determine
feasibility and efficacy of an anti-inflammatory dietary
intervention to lower levels of C-reactive protein in weight
stable postmenopausal women with abdominal obesity.MethodsThis
mixed-methods pilot study used a single arm pre-post design.
Thirteen women followed a 4-week anti-inflammatory, dietary
intervention, optimizing consumption of healthy fats, low glycemic
index wholegrains, and dietary antioxidants. Quantitative outcomes
included change in inflammatory and metabolic markers. Focus
groups were undertaken and thematically analyzed to explore
participants lived experience of following the diet.ResultsThere
was no significant change in plasma high-sensitivity C-reactive,
protein. Despite discouraging weight loss, median (Q1-Q3) body
weight decreased by -0.7 (-1.3 to 0 kg, P = 0.02). This was
accompanied by reductions in plasma insulin (0.90 [-0.05 to 2.20]
mmol/L), Homeostatic Model Assessment of Insulin Resistance (0.29
[-0.03 to 0.59]), and low-density lipoprotein:high-density
lipoprotein ratio (0.18 [-0.01 to 0.40]) (P & LE; 0.023 for all).
Thematic analysis revealed that postmenopausal women have a desire
to improve meaningful markers of health status that do not focus
on weight. Women were highly engaged with learning about emerging
and innovative nutrition topics, favoring a detailed and
comprehensive nutrition education style that challenged their
proficient health literacy and cooking skills.ConclusionsWeight-
neutral dietary interventions targeting inflammation can improve

metabolic markers and may be a viable strategy for CVD risk reduction in postmenopausal women. To determine effects on inflammatory status, a fully powered and longer-term randomized controlled trial is required. DETERMINATION OF THE CYTOTOXIC EFFECT ON
HUMAN COLON CANCER AND PHENOLIC SUBSTANCE CONTENT OF THE ENDEMIC
SPECIES SIDERITIS OZTURKII AYTAC & AKSOY APPLIED ECOLOGY AND
ENVIRONMENTAL RESEARCH English Article

Sideritis; cytotoxicity; cancer; phenolic;
DLD-1; MTT MOUNTAIN TEA; SCARDICA Sideritis L. species that we
based on in this study are annual or perennial flowering plants
which are widely used as herbal medicine, and also called mountain
tea or shepherd's tea. They are common in the Mediterranean
Region, the Balkans, Iberian Peninsula, Greece, Central Asia and
Anatolia. They are xerophytic shrub or herbs between 8 and 90 cm.
They usually grow on arid cliffs, calcareous slopes, high-altitude
mountainous regions (650-1400 m). Full bloom usually occurs in
July. It is commonly used in Albania, Greece, Kosova, Bulgaria,
Macedonia, Asia, Central Europe and Anatolia as herbal tea and for
therapeutic purposes. It is usually used to aid digestion,
strengthen the immune system, suppress common cold, allergy,
sinusitis and influenza and as therapeutic for pain and mild
anxiety. The methanol extracts obtained from the flower and leaf
parts of the species Sideritis ozturkii Aytac & Aksoy, which is
endemic in Turkey, were applied at different concentrations and
for different times on DLD-1 human colorectal cancer cells
cultured in RPMI-1640 medium. The cytotoxicity measurements were
made through the use of MTT and the cytotoxicity indices were
calculated using an Elisa Reader. As a result of the study, it was
determined that the flower and leaf extracts obtained from the

species *Sideritis ozturkii* exhibit cytotoxic activity on DLD-1 cells in a dose- and time-dependent manner. It is believed that the extracts obtained from the species *Sideritis ozturkii* could be beneficial as a natural anti-proliferative agent. Chemopreventive properties of raisins originating from Greece in colon cancer cells FOOD & FUNCTION English Article CELLULAR

ANTIOXIDANT ACTIVITY; ANTHOCYANIN-RICH EXTRACTS; VITIS-VINIFERA L.; NF-KAPPA-B; ELLAGIC ACID; APOPTOSIS; POLYPHENOLS; GLUTATHIONE; EXPRESSION; PHENOLICS Colorectal cancer is one of the major causes of cancer-related mortality in humans in both developed and developing countries. Dietary patterns influence the risk of colon cancer development, while plant-derived foods have gained great interest, due to the high content of antioxidants. Corinthian raisins (Currants, CR) and Sultanas (S) (*Vitis vinifera* L., Vitaceae) are dried vine fruits produced in Greece with many culinary uses in both the Mediterranean and the Western nutrition. In the present study, we investigated the effects of CR and S on human colon cancer cells. Methanol extracts of CR and S were used at different concentrations. The total polyphenol content and anti-radical activity were measured by Folin-Ciocalteu and DPPH, respectively. Antioxidant, anti-inflammatory and anti-proliferative effects on HT29 cell culture were evaluated. All extracts exhibited DPPH scavenging activity in a dose-dependent manner. Both products suppressed cell proliferation, while the levels of glutathione and cyclooxygenase 2 were significantly decreased. A significant reduction in IL-8 levels and NF-kappaB p65 activation was also observed. Both antioxidant and anti-inflammatory effects were dependent on the duration of exposure. Results indicate that the methanol extracts of CR and S exhibit anti-radical activity in vitro, as well as cancer preventive efficacy on colon cancer cells, with S having slightly higher activity. The beneficial properties of these unique dried grapes are attributed to their high content of phenolic compounds.

Comparative Gene Signature of (-)-Oleocanthal Formulation
Treatments in Heterogeneous Triple Negative Breast Tumor Models:
Oncological Therapeutic Target Insights NUTRIENTS
English Article (-)-
oleocanthal; extra-virgin olive oil; TNBC; MMTV-PyVT; PDX;
microarray VIRGIN OLIVE OIL; CANCER-CELLS; INHIBITS GROWTH;
EXPRESSION; METASTASIS; RECEPTOR; MYC; AGGRESSIVENESS;
IDENTIFICATION; CHEMOTHERAPY Triple negative breast cancer (TNBC)
heterogeneity and limited therapeutic options confer its
phenotypic aggressiveness. The discovery of anti-TNBC natural
products with valid molecular target(s) and defined
pharmacodynamic profile would facilitate their therapeutic
nutraceutical use by TNBC patients. The extra-virgin olive oil
(EVOO) is a key Mediterranean diet ingredient. S-(-)-Oleocanthal
(OC) leads the bioactive anti-tumor EVOO phenolic ingredients. A
previous study reported the solid dispersion formulated OC with
(+)-xylitol (OC-X) suppressed the in vivo progression and
recurrence of the TNBC MDA-MB-231 cells. This study investigates
the ability of OC-X formulation to suppress the in vivo
heterogeneous BC initiation and progression utilizing advanced
preclinical transgenic MMTV-PyVT and TNBC PDX mouse models.
Furthermore, the clustering of the gene expression profiles in
MMTV-PyVT and PDX mouse tumors treated with OC-X acquired by a
Clarion S microarray analysis identified the distinctly affected
genes. Several affected novel signature genes identified in

response to OC-X treatments and proved overlapped in both mouse and human tumor models, shedding some lights toward understanding the OC anticancer molecular mechanism and assisting in predicting prospective clinical outcomes. This study provides molecular and preclinical evidences of OC-X potential as a nutraceutical suppressing heterogeneous TNBC model and offers preliminary gene-level therapeutic mechanistic insights. of the Bioactive Fraction Obtained from *Aspergillus flavus*
isolated from El-Qussair Marine Environments EGYPTIAN JOURNAL OF
BOTANY English Article

Anticancer activity; Antimicrobial activity;
Antioxidant activity; GCMS; Marine fungi; Red sea DUE TO
THEIR diversity and chemo-diversity, marine fungi are renowned for
producing structurally distinct secondary metabolites and are
regarded as a viable source of novel treatments. This study aimed
to evaluate the antimicrobial activity of 26 fungal strains
collected from the Mediterranean and Red Seas at Sharm el-sheikh,
Marsa matrouh, Damietta, El-ain el-sobhy, and El-Qusair. Using the
well diffusion method with ethyl acetate, petroleum ether,
methanolic, and chloroformic extracts, the antibacterial activity
of each fungal isolate against pathogenic microbes was assessed.
Our research revealed that marine fungi, particularly those from
El-Qusair, possess potent antibacterial properties. The IC50
values for the cytotoxic activity of natural products extracted
with ethyl acetate and petroleum ether against human
hepatocellular cancer cell lines (HepG2 cells), human colon

carcinoma cell lines (HCT-116 cells), and human breast cancer cell lines (MCF-7 cells) were 62.13, 115.93, and 154.82g/mL, respectively. Using the DPPH free radical scavenging assay in triplicate and average values, the antioxidant activity of the active fraction was determined. Our findings revealed that the ethylacetate extract had the highest percent DPPH scavenging activity compared to petroleum ether extracts. Using GCMS, chromatographic separations of the active ethyl acetate extract were performed to determine the active principles responsible for the activities. [Khattab, Om Kalthoum H.; El-Nasr, A. A. Molecular epidemiology and genotype distribution of Human Papillomavirus (HPV) among Arab women in the state of Qatar

JOURNAL OF TRANSLATIONAL MEDICINE English

Article Human Papilloma

virus; Qatar; Genotyping; Prevalence; Arab women; Cytology

INVASIVE CERVICAL-CANCER; EXTENDED MIDDLE-EAST; POLYMERASE-CHAIN-REACTION; INFECTION; RISK; VACCINATION; POPULATION; VARIANTS; SAMPLES; BURDEN Background: Human Papilloma Virus

(HPV) infection is the major cause of cervical cancer worldwide. With limited data available on HPV prevalence in the Arab countries, this study aimed to identify the prevalence and genotypic distribution of HPV in the State of Qatar. Methods: 3008 cervical samples, exclusively of women with Arabic origin residing in Qatar were collected from the Women's Hospital and Primary Health Care Corporation in Doha, State of Qatar. HPV DNA detection was done using GP5+/6+ primers based real time-polymerase chain reaction (RT-PCR) assay followed by the usage of HPV type specific primers based RT-PCR reactions and Sanger sequencing for genotype identification. Results: Similar prevalence rates of HPV infection was identified in both Qatari and non-Qatari women at 6.2% and 5.9% respectively. HPV prevalence rate of 5.8% and 18.4% was identified in women with normal cytology and in women with abnormal cytology respectively. HPV 81, 11 and 16, in decreasing order were the most commonly identified genotypes. HPV 81 was the

most frequent low-risk genotype among women with both normal (74.0%) and abnormal (33.3%) cytology. HPV 16 (4.6%) was identified as the predominant high-risk HPV genotype among women with normal cytology and HPV 16, HPV 18, and HPV 56 (22.2% each) were the most common identified high-risk genotypes in women with abnormal cytology. Conclusions: The overall HPV prevalence in Arab women in Qatar was identified as 6.1% with an increased HPV prevalence seen in women with abnormal cytology results and no significant trends seen with age. In contrast to Western countries, we report a varied genotypic profile of HPV with a high prevalence of low-risk HPV genotype 81 among the Arab women residing in Qatar.

Association between healthy dietary patterns and markers of oxidative stress in the Sister Study

EUROPEAN JOURNAL OF NUTRITION

English

Article

Oxidative stress; F-

2-isoprostanes; Diet; Dietary patterns; Menopause CORONARY-HEART-DISEASE; MEDITERRANEAN DIET; QUALITY SCORES; RISK; INFLAMMATION; BIOMARKERS; EXERCISE; OBESITY; F-2-ISOPROSTANES; QUESTIONNAIRE

Purpose: We assessed the cross-sectional association between healthy dietary patterns [alternate Mediterranean diet (aMED), Dietary Approaches to Stop Hypertension (DASH), alternative Healthy Eating Index (aHEI), and Healthy Eating Index 2015 (HEI-2015)] and urinary biomarkers of oxidative stress. Methods: Between 2003 and 2009, the Sister Study enrolled 50,884 breast cancer-free US women aged 35 to 74 (non-Hispanic White, 83.7%). Data were analyzed for 844 premenopausal and 454 postmenopausal women who had urine samples analyzed for F-2-isoprostanes and non-missing covariate data. Food frequency questionnaire responses were used to calculate dietary pattern scores. Concentrations of 8-iso-prostaglandin F-2 alpha (8-iso-PGF(2 alpha)) and its metabolite (8-iso-PGF(2 alpha)-M) were measured in urine samples by GC/MS for premenopausal women and LC/MS for postmenopausal women.

Multivariable linear regression models were used to estimate associations between aMED, DASH, aHEI, and HEI-2015 and urinary F-2-isoprostanes by menopausal status. Effect modification by sociodemographic, lifestyle, and clinical characteristics was also evaluated. Results: Among premenopausal women, the four dietary indices were inversely associated with 8-iso-PGF(2 alpha) (aMED beta(Q4vsQ1): - 0.17, 95% CI - 0.27, - 0.08; DASH beta(Q4vsQ1): - 0.18, 95% CI - 0.28, - 0.08; aHEI beta(Q4vsQ1): - 0.20, 95% CI - 0.30, - 0.10; HEI-2015 beta(Q4vsQ1): - 0.19, 95% CI - 0.29, - 0.10). In contrast, inverse associations with 8-iso-PGF(2 alpha)-M were found for the continuous aMED, aHEI, and HEI-2015.

Associations between dietary indices and 8-iso-PGF(2 alpha) were generally stronger among younger women, women with lower income, and women with higher BMI. Similar results were observed among postmenopausal women, though only the continuous DASH and aHEI models were statistically significant. Conclusion: Healthy dietary patterns were associated with lower levels of oxidative stress.

OXYCEDRUS; SIBTH.; CUPRESSACEAE; BERRIES; BALL. In this work, we conducted a comparative phytochemical, chemotaxonomic, and biological study of essential oils (EOs) and extracts (ethyl acetate and methanol) obtained from the leaves of *Juniperus macrocarpa* and *J. oxycedrus*. The dominant compounds of *J. macrocarpa* EO, analysed by gas chromatography (GC) and gas chromatography-mass spectrometry (GC-MS), are oc-pinene, sabinene, manoyl oxide, and germacrene D, whereas oc-pinene, limonene, (Z,E)-farnesol, beta-pinene, and gamma-cadinene are the most representative volatiles of *J. oxycedrus* EOs. A multivariate analysis of EOs, included a selection of literature data comparing our samples to samples of *J. oxycedrus/macrocarpa/deltoides* from the Mediterranean area, was performed. As evident by high-performance liquid chromatography (HPLC) analyses, apigenin, (-)-epicatechin, and luteolin were abundant in *J. oxycedrus* extracts, while gallic acid, kaempferol-3-O-glucoside, and protocatechuic acid were the dominant constituents of *J. macrocarpa* extracts. EOs and extracts have been investigated for their potential antioxidant properties and anti-proliferative activity against lung adenocarcinoma (A549), breast cancer (MCF-7 and MDA-MB-231), and lung large cell carcinoma (COR-L23) human cell lines. The methanol and ethyl acetate extracts of *J. oxycedrus* exerted the most valuable antioxidant activity and exhibited the most

promising activity against the COR-L23 cell line with an IC50 of 26.0 and 39.1 $\mu\text{g/mL}$, respectively, lower than that obtained with the positive control (IC50 of 45.5 $\mu\text{g/mL}$). To the best of our knowledge, this is the first report highlighting the anti-proliferative activity of *J. oxycedrus* and *J. macrocarpa* extracts against this lung cancer cell line. Our results indicate that *J. oxycedrus* may be considered a source of natural compounds with antioxidant and anti-proliferative effects that could be suitable for future applications.  Nafiseh Phycocyanin C a Natural Product with
 Impressive Therapeutic Efficacy for Inhibition of Breast Tumors'
 Growth and Metastasis in Vivo MIDDLE EAST JOURNAL OF CANCER
 English Article

Phycocyanin C; Breast neoplasm; Metastasis MATRIX
 METALLOPROTEINASES; MOLECULAR-MECHANISMS; CANCER CELLS; APOPTOSIS;
 ANTIOXIDANT; COX-2; VITRO; CONSUMPTION; WINE Background: Several
 studies have reported the anticancer effect of phycocyanin C, a
 natural extract isolated from the algae *Arthrospira platensis*.
 However, its therapeutic effects on the growth of breast cancer
 and its metastasis have not been determined yet. Method: In this
 case-control study, we employed phycocyanin C for the treatment of
 4T1 breast tumor as an applicable experimental animal model for
 human mammary cancer and metastasis. BALB/c mice were injected
 subcutaneously (s.c) into the 4th abdominal mammary fat pad with 1
 $\times 10^6$ 4T1 cells. We randomly divided the mice into two groups;
 one group of mice were injected with PBS as the control, and the
 other group was intraperitoneally injected with phycocyanin C (80
 mg/kg daily for 20 days). Tumor growth and metastasis were
 assessed in both groups. Results: Phycocyanin C significantly

inhibited 4T1 breast tumors growth ($P < 0.05$). The mean tumors volumes at the control group were 2.73 times higher than those of the treatment group. In addition, phycocyanin C treatment could significantly inhibit the formation of metastasis colonies at vital organs like spleen, liver, and lung. Moreover, the survival rate of the tumor-bearing mice increased after about 22 days by phycocyanin C treatment in comparison with the control.

Conclusion: This is the first report demonstrating the anticancer effects of phycocyanin C on 4T1 breast tumor in vivo. Overall, our findings provided convincing evidence for the application of phycocyanin C as an anticancer therapeutic agent. J Lee, IM; Shiroma, EJ; Lobelo, F; Puska, P; Blair, SN; Katzmarzyk, PT Lee, I-Min; Shiroma, Eric J.; Lobelo, Felipe; Puska, Pekka; Blair, Steven N.; Katzmarzyk, Peter T. Lancet Phys Activity Series Workin Effect of physical inactivity on major non-communicable diseases worldwide: an analysis of burden of disease and life expectancy LANCET English Article

ALL-CAUSE MORTALITY; CORONARY-HEART-DISEASE; BREAST-CANCER; METAANALYSIS; RISK; SMOKING; POPULATION; INTENSITY; CHINA

Background Strong evidence shows that physical inactivity increases the risk of many adverse health conditions, including major non-communicable diseases such as coronary heart disease, type 2 diabetes, and breast and colon cancers, and shortens life expectancy. Because much of the world's population is inactive, this link presents a major public health issue. We aimed to quantify the effect of physical inactivity on these major non-communicable diseases by estimating how much disease could be averted if inactive people were to become active and to estimate gain in life expectancy at the population level. Methods For our analysis of burden of disease, we calculated population attributable fractions (PAFs) associated with physical inactivity using conservative assumptions for each of the major non-communicable diseases, by country, to estimate how much disease

could be averted if physical inactivity were eliminated. We used life-table analysis to estimate gains in life expectancy of the population. Findings Worldwide, we estimate that physical inactivity causes 6% (ranging from 3.2% in southeast Asia to 7.8% in the eastern Mediterranean region) of the burden of disease from coronary heart disease, 7% (3.9-9.6) of type 2 diabetes, 10% (5.6-14.1) of breast cancer, and 10% (5.7-13.8) of colon cancer. Inactivity causes 9% (range 5.1-12.5) of premature mortality, or more than 5.3 million of the 57 million deaths that occurred worldwide in 2008. If inactivity were not eliminated, but decreased instead by 10% or 25%, more than 533 000 and more than 1.3 million deaths, respectively, could be averted every year. We estimated that elimination of physical inactivity would increase the life expectancy of the world's population by 0.68 (range 0.41-0.95) years. Interpretation Physical inactivity has a major health effect worldwide. Decrease in or removal of this unhealthy behaviour could improve health substantially. [Lee, I-Min]

Polyp Prevention Trial Study Grp The Effect of Strict Adherence to a High-Fiber, High-Fruit and -Vegetable, and Low-Fat Eating Pattern on Adenoma Recurrence AMERICAN JOURNAL OF EPIDEMIOLOGY English Article

adenoma; colorectal neoplasms; dietary fiber; patient compliance; polyps COLON-CANCER; DIETARY FIBER; MEDITERRANEAN DIET; COLORECTAL-CANCER; RANDOMIZED TRIAL; RISK; INTERVENTION; PREVENTION Individual differences in dietary intake are thought to account for substantial variation in cancer incidence. However, there has been a consistent lack of effect for low-fat, high-fiber dietary interventions and risk of colorectal cancer. These inconsistencies may reflect the multistage process of cancer as well as the range and timing of dietary change. Another potential reason for the lack of effect is poor dietary adherence among participants in these trials. The authors examined the effect of strict adherence to a low-fat, high-fiber, high-fruit and -vegetable intervention over 4 years among participants (n = 1,905) in the US Polyp Prevention Trial (1991-1998) on colorectal adenoma recurrence. There was a wide range of individual variation in the level of compliance among intervention participants. The most adherent participants, defined as "super compliers" (n = 210), consistently reported that they met or exceeded each of the 3 dietary goals at all 4 annual visits. Multivariate logistic regression models were used to estimate the association between dietary adherence and adenoma recurrence. The authors observed a 35% reduced odds of adenoma recurrence among super compliers compared with controls (odds ratio = 0.65, 95% confidence interval: 0.47, 0.92). Findings suggest that high compliance with a low-fat, high-fiber diet is associated with reduced risk of adenoma recurrence.  2021 Fertility Forecasting Collaborators Global fertility in
 204 countries and territories, 1950-2021, with forecasts to 2100:
 a comprehensive demographic analysis for the Global Burden of
 Disease Study 2021 LANCET English Article

REPRODUCTIVE HEALTH;
ECONOMIC-GROWTH; POPULATION; EDUCATION; IMPACT; EMPOWERMENT;
TRANSITION; POLICIES; OUTCOMES; AFRICA Background Accurate
assessments of current and future fertility-including overall
trends and changing population age structures across countries and
regions-are essential to help plan for the profound social,
economic, environmental, and geopolitical challenges that these
changes will bring. Estimates and projections of fertility are
necessary to inform policies involving resource and health-care
needs, labour supply, education, gender equality, and family
planning and support. The Global Burden of Diseases, Injuries, and
Risk Factors Study (GBD) 2021 produced up-to-date and
comprehensive demographic assessments of key fertility indicators
at global, regional, and national levels from 1950 to 2021 and
forecast fertility metrics to 2100 based on a reference scenario
and key policy-dependent alternative scenarios. Methods To
estimate fertility indicators from 1950 to 2021, mixed-effects
regression models and spatiotemporal Gaussian process regression
were used to synthesise data from 8709 country-years of vital and
sample registrations, 1455 surveys and censuses, and 150 other
sources, and to generate age-specific fertility rates (ASFRs) for
5-year age groups from age 10 years to 54 years. ASFRs were summed
across age groups to produce estimates of total fertility rate
(TFR). Livebirths were calculated by multiplying ASFR and age-
specific female population, then summing across ages 10-54 years.
To forecast future fertility up to 2100, our Institute for Health
Metrics and Evaluation (IHME) forecasting model was based on
projections of completed cohort fertility at age 50 years (CCF50;
the average number of children born over time to females from a
specified birth cohort), which yields more stable and accurate
measures of fertility than directly modelling TFR. CCF50 was
modelled using an ensemble approach in which three sub-models
(with two, three, and four covariates variously consisting of
female educational attainment, contraceptive met need, population
density in habitable areas, and under-5 mortality) were given
equal weights, and analyses were conducted utilising the MR-BRT
(meta-regression-Bayesian, regularised, trimmed) tool. To capture
time-series trends in CCF50 not explained by these covariates, we
used a first-order autoregressive model on the residual term.
CCF50 as a proportion of each 5-year ASFR was predicted using a
linear mixed-effects model with fixed-effects covariates (female
educational attainment and contraceptive met need) and random
intercepts for geographical regions. Projected TFRs were then
computed for each calendar year as the sum of single-year ASFRs
across age groups. The reference forecast is our estimate of the
most likely fertility future given the model, past fertility,
forecasts of covariates, and historical relationships between
covariates and fertility. We additionally produced forecasts for
multiple alternative scenarios in each location: the UN
Sustainable Development Goal (SDG) for education is achieved by
2030; the contraceptive met need SDG is achieved by 2030; pro-
natal policies are enacted to create supportive environments for
those who give birth; and the previous three scenarios combined.
Uncertainty from past data inputs and model estimation was
propagated throughout analyses by taking 1000 draws for past and
present fertility estimates and 500 draws for future forecasts
from the estimated distribution for each metric, with 95%
uncertainty intervals (UIs) given as the 2 center dot 5 and 97

center dot 5 percentiles of the draws. To evaluate the forecasting performance of our model and others, we computed skill values—a metric assessing gain in forecasting accuracy—by comparing predicted versus observed ASFRs from the past 15 years (2007–21). A positive skill metric indicates that the model being evaluated performs better than the baseline model (here, a simplified model holding 2007 values constant in the future), and a negative metric indicates that the evaluated model performs worse than baseline.

Findings During the period from 1950 to 2021, global TFR more than halved, from 4 center dot 84 (95% UI 4 center dot 63–5 center dot 06) to 2 center dot 23 (2 center dot 09–2 center dot 38). Global annual livebirths peaked in 2016 at 142 million (95% UI 137–147), declining to 129 million (121–138) in 2021. Fertility rates declined in all countries and territories since 1950, with TFR remaining above 2 center dot 1—canonically considered replacement-level fertility—in 94 (46 center dot 1%) countries and territories in 2021. This included 44 of 46 countries in sub-Saharan Africa, which was the super-region with the largest share of livebirths in 2021 (29 center dot 2% [28 center dot 7–29 center dot 6]). 47 countries and territories in which lowest estimated fertility between 1950 and 2021 was below replacement experienced one or more subsequent years with higher fertility; only three of these locations rebounded above replacement levels. Future fertility rates were projected to continue to decline worldwide, reaching a global TFR of 1 center dot 83 (1 center dot 59–2 center dot 08) in 2050 and 1 center dot 59 (1 center dot 25–1 center dot 96) in 2100 under the reference scenario. The number of countries and territories with fertility rates remaining above replacement was forecast to be 49 (24 center dot 0%) in 2050 and only six (2 center dot 9%) in 2100, with three of these six countries included in the 2021 World Bank-defined low-income group, all located in the GBD super-region of sub-Saharan Africa. The proportion of livebirths occurring in sub-Saharan Africa was forecast to increase to more than half of the world's livebirths in 2100, to 41 center dot 3% (39 center dot 6–43 center dot 1) in 2050 and 54 center dot 3% (47 center dot 1–59 center dot 5) in 2100. The share of livebirths was projected to decline between 2021 and 2100 in most of the six other super-regions—decreasing, for example, in south Asia from 24 center dot 8% (23 center dot 7–25 center dot 8) in 2021 to 16 center dot 7% (14 center dot 3–19 center dot 1) in 2050 and 7 center dot 1% (4 center dot 4–10 center dot 1) in 2100—but was forecast to increase modestly in the north Africa and Middle East and high-income super-regions. Forecast estimates for the alternative combined scenario suggest that meeting SDG targets for education and contraceptive met need, as well as implementing pro-natal policies, would result in global TFRs of 1 center dot 65 (1 center dot 40–1 center dot 92) in 2050 and 1 center dot 62 (1 center dot 35–1 center dot 95) in 2100. The forecasting skill metric values for the IHME model were positive across all age groups, indicating that the model is better than the constant prediction. Interpretation Fertility is declining globally, with rates in more than half of all countries and territories in 2021 below replacement level. Trends since 2000 show considerable heterogeneity in the steepness of declines, and only a small number of countries experienced even a slight fertility rebound after their lowest observed rate, with none reaching replacement level. Additionally, the distribution of livebirths across the globe is shifting, with a greater proportion occurring in the

lowest-income countries. Future fertility rates will continue to decline worldwide and will remain low even under successful implementation of pro-natal policies. These changes will have far-reaching economic and societal consequences due to ageing populations and declining workforces in higher-income countries, combined with an increasing share of livebirths among the already poorest regions of the world. It is no secret that the world is facing the challenge of
transitioning to healthy diets, which link human and planetary
health and the economy. Among the wide variety of diets,
Palaeolithic diet has become so popular in social media. The main
goal of this study is to evaluate the environmental and health
sustainability of the Paleo diet, incorporating the health
dimension to the economic, nutritional, and environmental
indicators. Results were compared with those of the other dietary
patterns in Spain: Mediterranean Diet (MD), Southern European
Atlantic Diet (SEAD) and the Spanish Dietary Guidelines (NAOS). It
was concluded that the Paleo diet is a diet low in carbohydrates
(24.5% of energy intake) and high in protein (29.6% of energy
intake), cholesterol (835 mg.day⁻¹) and polyunsaturated fatty
acids (15.3% of energy intake). The diet quality score was 260, a
result above the recommended. Regarding the health assessment of
the food categories that contribute most to the Paleo diet,
vegetables and fruits were associated with a lower risk of
cardiovascular disease (CVD), type 2 diabetes mellitus (T2D),
colorectal cancer (CRCA), obesity and stroke. The opposite result
was observed for red meat. Fish and seafood, as well as poultry,
were associated with a relative risk higher than one for T2D and
obesity, but not for CVD, CRCA or stroke. Based on the economic
assessment, a higher dietary cost was estimated for Paleo diet
(8.6(sic).person⁻¹.day⁻¹). The environmental metrics in terms
of carbon footprint (CF) and water footprint (WF) were estimated
in 5.44 kg CO₂.person⁻¹.day⁻¹ and 3499 L.person⁻¹.day⁻¹
respectively, a worse environmental profile than that of MD, SEAD
and NAOS. Environmental and health sustainability assessments can
help policy makers set targets for improving dietary guidelines at
national level. They are recognized as a very useful tool to guide
citizens towards the most appropriate diet. (C) 2021 Elsevier B.V.

Colorectal cancer (CRC) is ranked the second most lethal type of tumor globally. Thus, developing novel anti-cancer therapeutics that are less aggressive and more potent is needed. Recently, natural bioactive molecules are gaining interest as complementary and supportive antineoplastic treatments due to their safety, effectiveness, and low cost. *Jania rubens* (*J. rubens*) is a red coral seaweed abundant in the Mediterranean and bears a significant pharmacological essence. Despite its therapeutic potential, the natural biomolecules extracted from this alga are poorly identified. In this study, the proximal analysis revealed high levels of total ash content (66%), 11.3% proteins, 14.5% carbohydrates, and only 4.5% lipids. The elemental identification showed magnesium and calcium were high among its macro minerals, (24 +/- 0.5 mg/g) and (33 +/- 0.5 mg/g), respectively. The Chlorophyll of *J. rubens* was dominated by other

pigments with (0.82 +/- 0.02 mg/g). A 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging assay identified effective antioxidant activity in various *J. rubens* extracts. More importantly, a 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) tetrazolium reduction and wound healing assays indicate that organic extracts from *J. rubens* significantly counteract the proliferation of colon cancer cell lines (HCT-116 and HT-29) and inhibit their migratory and metastatic properties in a dose and time-dependent manner. Overall, this study provides insight into the physicochemical properties of red seaweed, *J. rubens*, and identifies its significant antioxidant, cytotoxic, and anti-migratory potential on two colorectal cell lines, HCT-116 and HT-29. MEDITERRANEAN DIET; COLORECTAL-CANCER; FUNCTIONAL FOOD;
ANTIMUTAGENS; 1,2-DIMETHYLHYDRAZINE; FERMENTATION; MICROBIOTA;
TOXICOLOGY Background: Colorectal cancer is a highly prevalent
disease, requiring effective strategies for prevention and
treatment. The present research aimed to formulate a natural
fiber-rich food product (NFRFP) and to evaluate its safety,
toxicogenetics, and effects on aberrant crypt foci induced by 1,2-
dimethyl-hydrazine in a preclinical model. Methods: A total of 78
male Wistar rats were distributed in six experimental groups:
negative control, positive control (1,2-Dimethylhydrazine-40
mg/Kg), and four groups fed with 10% NFRFP: NFRFP, pre-treatment
protocol, simultaneous treatment, and post-treatment protocol.
Results: The NFRFP was shown to be a good source of fibers and did
not change biometric, biochemical, hematological, and inflammatory
parameters, and did not induce signs of toxicity and
genotoxicity/carcinogenicity. NFRFP exhibited a chemopreventive
effect, in all protocols, with damage reduction (% DR) of 75% in
the comet test. NFRFP reduced the incidence of aberrant crypt
outbreaks by 49.36% in the post-treatment protocol. Conclusions:
The results suggest the applicability of NFRFP in the human diet
due to potential production at an industrial scale and easy
technological application in different products, since it could be
incorporated in food without altering or causing small changes in
final product sensory characteristics. [do Amaral, Luane

J Mousa, M; Al-Jefout, M; Alsafar, H; Becker, CM; Zondervan, KT; Rahmioglu, N Mousa, Mira; Al-Jefout, Moamar; Alsafar, Habiba; Becker, Christian M.; Zondervan, Krina T.; Rahmioglu, Nilufer Impact of Endometriosis in Women of Arab Ancestry on: Health-Related Quality of Life, Work Productivity, and Diagnostic Delay FRONTIERS IN GLOBAL WOMENS HEALTH English Article

quality of life; endometriosis; global health; women's health; Middle East; Arab women; diagnostic delay; work productivity and activity impairment CHRONIC PELVIC PAIN; SURVEY SF-36; PSYCHOSOCIAL FACTORS; ESHRE GUIDELINE; BREAST-CANCER; RATING-SCALE; NUMERIC PAIN; ADOLESCENTS; ASSOCIATION; SYMPTOMS Introduction Endometriosis has a negative effect on health-related quality of life (HRQoL), wellbeing and daily functioning. Endometriosis is an under-researched condition within non-western populations. Cultural representations are needed to understand the relative roles of societal norms, traditional factors, and religious sensitivities on the impact of endometriosis on HRQoL in various populations. In particular, there is a lack of emphasis placed in understanding the association of HRQoL on endometriosis in Arab women. Method In this prospective case-control study, 2,610 Arab ancestry women in the United Arab Emirates were recruited to investigate the impact of endometriosis on HRQoL, diagnostic delay, psychological co-morbidities, work productivity, and physical activity. Participants completed the following standardized, validated questionnaires: Short Form-36 version 2 questionnaire, the World Endometriosis Research Foundation EPHeCt minimum clinical questionnaire version, and Work Productivity and Activity Impairment questionnaire. Translations to the Arabic language, validated using the forward-backward translation method, of the questionnaires were utilized. Results HRQoL scores were significantly impaired in women with endometriosis, as demonstrated in the Physical Composite Scores and Mental Composite Scores in the symptomatic control group ($p = 0.001$; $p = 0.003$, respectively) and the asymptomatic control group ($p < 0.001$; $p < 0.001$, respectively). Susceptibility and severity of multiple pain syndromes and infertility in women with endometriosis was the main indicator of lower HRQoL. Anxiety ($p = 0.007$) and depression ($p = 0.005$) were significantly associated with endometriosis, in comparison to symptomatic controls. The average diagnostic delay was 11.61 years, however single women experience 15.81 years of diagnosis delay, with approximately 18% ($n = 15$) of the single women experiencing more than a 20-year delay in diagnosis. The intensity of physical activity was not associated with endometriosis, when compared to symptomatic ($p = 0.405$) or asymptomatic controls ($p = 0.144$). Conclusion For the first time, we provide evidence from a combined hospital, clinic, and population-based study that Arab women with endometriosis experience significant impacts on HRQoL, substantial diagnostic delay after the onset of symptoms, significant association to psychological disorders (anxiety and depression), and a negative impact on work productivity. Future research must focus on understanding the personal and culturally centered beliefs of Arab women to ensure a positive HRQoL trajectory by improving diagnosis and management strategies. WHO World

Mental Hlth Survey Colla The cross-national epidemiology of social anxiety disorder: Data from the World Mental Health Survey Initiative BMC MEDICINE English Article

Social anxiety disorder; Social phobia; Cross-national epidemiology; World Mental Health Survey Initiative PHOBIA; VERSION; FEARS Background: There is evidence that social anxiety disorder (SAD) is a prevalent and disabling disorder. However, most of the available data on the epidemiology

of this condition originate from high income countries in the West. The World Mental Health (WMH) Survey Initiative provides an opportunity to investigate the prevalence, course, impairment, socio-demographic correlates, comorbidity, and treatment of this condition across a range of high, middle, and low income countries in different geographic regions of the world, and to address the question of whether differences in SAD merely reflect differences in threshold for diagnosis. Methods: Data from 28 community surveys in the WMH Survey Initiative, with 142,405 respondents, were analyzed. We assessed the 30-day, 12-month, and lifetime prevalence of SAD, age of onset, and severity of role impairment associated with SAD, across countries. In addition, we investigated socio-demographic correlates of SAD, comorbidity of SAD with other mental disorders, and treatment of SAD in the combined sample. Cross-tabulations were used to calculate prevalence, impairment, comorbidity, and treatment. Survival analysis was used to estimate age of onset, and logistic regression and survival analyses were used to examine socio-demographic correlates. Results: SAD 30-day, 12-month, and lifetime prevalence estimates are 1.3, 2.4, and 4.0% across all countries. SAD prevalence rates are lowest in low/lower-middle income countries and in the African and Eastern Mediterranean regions, and highest in high income countries and in the Americas and the Western Pacific regions. Age of onset is early across the globe, and persistence is highest in upper-middle income countries, Africa, and the Eastern Mediterranean. There are some differences in domains of severe role impairment by country income level and geographic region, but there are no significant differences across different income level and geographic region in the proportion of respondents with any severe role impairment. Also, across countries SAD is associated with specific socio-demographic features (younger age, female gender, unmarried status, lower education, and lower income) and with similar patterns of comorbidity. Treatment rates for those with any impairment are lowest in low/lower-middle income countries and highest in high income countries. Conclusions: While differences in SAD prevalence across countries are apparent, we found a number of consistent patterns across the globe, including early age of onset, persistence, impairment in multiple domains, as well as characteristic socio-demographic correlates and associated psychiatric comorbidities. In addition, while there are some differences in the patterns of impairment associated with SAD across the globe, key similarities suggest that the threshold for diagnosis is similar regardless of country income levels or geographic location. Taken together, these cross-national data emphasize the international clinical and public health significance of SAD.  Zeljana A Plant Worthy of Further Study-Volatile
 and Non-Volatile Compounds of Portenschlagiella ramosissima
 (Port.) Tutin and Its Biological Activity PHARMACEUTICALS
 English Article

Portenschlagiella ramosissima; volatilome; essential oil;
 hydrosol; gas chromatography-mass spectrometry; headspace
 microextraction; myristicin; antiphytoviral; antiproliferative
 activity CHEMICAL-COMPOSITION; ESSENTIAL OIL; IN-VITRO;

CYTOTOXIC ACTIVITY; APIACEAE New and detailed data are presented on the phytochemical composition of the volatile and non-volatile organic compounds of the Mediterranean endemic species *Portenschlagiella ramosissima* (Port.) Tutin. Both the essential oil and hydrosol were obtained from the air-dried plant by hydrodistillation and analyzed by gas chromatography-mass spectrometry. The volatile compounds from the fresh and air-dried plants and from the hydrosol were isolated for the first time by headspace solid-phase microextraction using two fibres of different polarity. The benzene derivative group was the predominant group in all samples, with myristicin being the most abundant component of all. The non-volatile compounds of the methanol extract were analyzed by ultra-high-performance liquid chromatography-high-resolution mass spectrometry with electrospray ionisation, and three flavonoid glycosides, one anthocyanidin glycoside, and lipid derivatives were detected. Both the chemical composition and biological activities of this plant have been described in a very limited number of publications, making it an interesting source for further study. The antiphytoviral activity of the essential oil and hydrosol showed that both extracts significantly reduced the number of lesions on the leaves of local host plants infected with tobacco mosaic virus. Moderate antiproliferative activity of the methanol extract was detected in three cancer cell lines, cervical cancer cell line, human colon cancer cell line and human osteosarcoma cell line, using the MTS-based cell proliferation assay. Based on the results, we highlight this plant as a new source of bioactive compounds and natural phytotherapeutic agent that deserves further investigation.

Consortium Hlth & Ageing Network C Quantification of the smoking-associated cancer risk with rate advancement periods: meta-analysis of individual participant data from cohorts of the CHANCES consortium BMC MEDICINE English

Article Smoking; Cancer; Incidence; Mortality; Cohort; Meta-analysis CIGARETTE-SMOKING; PROSTATE-CANCER; BREAST-CANCER; EPIDEMIOLOGIC EVIDENCE; MEDITERRANEAN DIET; COLORECTAL-CANCER; PANCREATIC-CANCER; QUITTING SMOKING; TOBACCO; IMPACT Background: Smoking is the most important individual risk factor for many cancer sites but its association with breast and prostate cancer is not entirely clear. Rate advancement periods (RAPs) may enhance communication of smoking related risk to the general population. Thus, we estimated RAPs for the association of smoking exposure (smoking status, time since smoking cessation, smoking intensity, and duration) with total and site-specific (lung, breast, colorectal, prostate, gastric, head and neck, and pancreatic) cancer incidence and mortality. Methods: This is a meta-analysis of 19 population-based prospective cohort studies with individual participant data for 897,021 European and American adults. For each cohort we calculated hazard ratios (HRs) for the association of smoking exposure with cancer outcomes using Cox regression adjusted for a common set of the most important potential confounding variables. RAPs (in years) were calculated as the ratio of the logarithms of the HRs for a given smoking exposure variable and age. Meta-analyses were employed to summarize cohort-specific HRs and RAPs. Results: Overall, 140,205 subjects had a first incident cancer, and 53,164 died from cancer, during an average follow-up of 12 years. Current smoking advanced the overall risk of developing and dying from cancer by eight and ten years, respectively, compared with never smokers. The greatest advancements in cancer risk and mortality were seen for lung cancer and the least for breast cancer. Smoking cessation was statistically significantly associated with delays in the risk of cancer development and mortality compared with continued smoking. Conclusions: This investigation shows that smoking, even among older adults, considerably advances, and cessation delays, the risk of developing and dying from cancer. These findings may be helpful in more effectively communicating the harmful effects of smoking and the beneficial effect of smoking cessation. The CHANCES project (www.chancesfp7.eu) is coordinated by the Hellenic Health Foundation, Greece. The Cohort of Swedish Men (CORM) and the Swedish Mammography Cohort (SMC) were supported by research grants from the Swedish Research Council and the Swedish Cancer Foundation. The ESTHER study was funded by the Baden-Wurttemberg state Ministry of Science, Research and Arts (Stuttgart, Germany), the Federal Ministry of Education and Research (Berlin, Germany), and the Federal Ministry of Family Affairs, Senior Citizens, Women and Youth (Berlin, Germany). The EPIC Greece study was funded by the Hellenic Health Foundation. The EPIC Netherlands study was funded by European Commission (DG SANCO), Dutch Ministry of Public Health, Welfare and Sports (VWS), The National Institute for Public Health and the Environment (RIVM), the Netherlands Cancer Registry (NKR), the

Netherlands Organizaton for Health Research and Development (ZONMW), the World Cancer Research Fund (WCRF) and Statistics Netherlands. The EPIC Spain study was supported by Health Research Fund (FIS) of the Spanish Ministry of Health RTICC 'Red Tematica de Investigacion Cooperativa en Cancer (Grant numbers: Rd06/0070/0091 and Rd12/0036/0018), Regional Governments of Andalucia, Asturias, Basque Country, Murcia (project 6236) and Navarra, Institute de Salud Carlos III, Redes de Investigacion Cooperativa (RD06/0020). The EPIC Sweden study was funded by the Swedish Cancer Society, the Swedish Scientific Council and the Regional Government of Skane. The EPIC Denmark study was funded by the Danish Cancer Society. The HAPIEE study was funded by the Wellcome Trust (064947 and 081081), the US National Institute on Ageing (R01 AG23522), and a grant from Mac Arthur Foundation. MORGAM PRIME was supported by grants from the Institut National de la Sante et de la Recherche Medicale (INSERM), Merck, Sharp & Dohme-Chibret Laboratory and the Department of Health and Social Services and Personal Safety for Northern Ireland. In addition to the FP7 ftmding for CHANCES, the MORGAM project received funding from the European Union FP7 projects ENGAGE (HEALTH-F4-2007-201413) and BiomarCaRE (278913). This supported central coordination, workshops and part of the activities of the MORGAM Data Center at THL in Helsinki, Finland. MORGAM Participating Centers are funded by regional and national governments, research councils, charities, and other local Socities. The National Institutes of Health (NIH)-AARP cohort was funded by the Intramural Program of the National Cancer Institute. The Rotterdam Study (RS) is supported by the Erasmus Medical Center and Erasmus University Rotterdam; the Netherlands Organization for Scientific Research; the Netherlands Organization for Health Research and Development; the Research Institute for Diseases in the Elderly; the Netherlands Genomics Initiative; the Ministry of 'Education Culture, and Science; the Ministry of Health, Welfare, and Sports; the European Commission; and the Municipality of Rotterdam. The SENECA study was funded as a Concerted Action within the EURONUT programme of the EU. The TROMSO Study was funded by the Norwegian Research Council and peformed by the University of Tromso in cooperation the National Health Screening Service. The Vasterbotten Intervention Program (VIP) was supported by grants from the Vasterbotten county Council, the Swedish Council for Working Life and Social Research, and the Swedish Research Council. The study's funders had no influence on the design of the study, analysis and interpretation of the data, writing, review, approval or submission of the manuscript.

Design, Synthesis, Characterization, and Biological
Evaluation of Indole-2-Carboxamide Derivatives as Potent Anti-
Cancer Agents JORDAN JOURNAL OF CHEMISTRY English
Article Synthesis; cancer;

indole-2-carboxamide derivatives; NMR; cell lines; organic
chemistry INDOLE ALKALOIDS; DISCOVERY Cancer disease often
spreads and causes premature death. Chemotherapy using
heterocyclic compounds, like indoles, promises to be an effective
option for cancer treatment. Simple procedures were introduced to
prepare seven 1H-indole-2-carboxamide derivatives.
Characterization was performed using spectroscopic techniques such
as infrared and nuclear magnetic resonance spectroscopy, and
elemental analysis. The prepared compounds were evaluated
biologically against human prostate cancer cell line (PC3), human,
invasive breast ductal carcinoma (MCF-7), and breast cancer cell
line-231 (MDA) alongside normal dermal fibroblasts. All compounds
showed a moderate potency in PC3 having 23 to >50 μ g/mL half
maximal inhibitory concentration. The activity of the compounds
was based on the presence of N-H in the indole system, amide, and
phenyl groups at the specified positions. The synthesized
compounds exhibited no inhibitory activity against the MDA cancer
cell line. [Aljabra, Ghofran; Abu-Qatouseha, Luay; Mansoor, K,

J Raychaudhuri, S; Bajaj, A; Agarwal, C; Pujani, M; Singh, K; Chauhan, V; Gupta, E Raychaudhuri, Sujata; Bajaj, Akanksha; Agarwal, Charu; Pujani, Mukta; Singh, Kanika; Chauhan, Varsha; Gupta, Ekta Immunohistochemistry-Based Molecular Subtyping of Breast Carcinoma in Industrial Population in India, Haryana: A Correlation with Clinicopathological Parameters MIDDLE EAST JOURNAL OF CANCER English Article Breast; Immunohistochemistry; Molecular subtyping; Industrial population CANCER SUBTYPES; PROGESTERONE-RECEPTOR; HORMONE-RECEPTOR; ESTROGEN-RECEPTOR; EXPRESSION; RECURRENCE; SURVIVAL; FEATURES; HER2; AGE Background: Breast carcinoma is the most prevalent malignancy in females globally and also the leading cause of cancer-related mortality. The immunohistochemistry (IHC)-based molecular subtyping has put newer insights into the biological behaviour and clinical management of breast carcinoma. We conducted the present study to correlate the four IHC-based molecular subtypes: Luminal A, Luminal B, Human epidermal growth factor receptor 2 positive, and triple negative breast carcinoma with various clinicopathological parameters amongst the industrial population of Haryana. Method: This cross-sectional study was conducted on 92 cases of invasive breast carcinoma, who underwent modified radical mastectomy over a period of 2.5 years with the prior approval of Institutional Ethical Committee at ESIC Medical College and Hospital, Faridabad. We performed routine histopathological examination along with IHC (Estrogen receptor, Progesterone receptor and Human epidermal growth factor receptor 2) study. The correlation of the four molecular subtypes with various clinicopathological parameters were also studied. We analysed the data using SPSS software. Results: The mean age of the patients in this study was 47 years with a maximum number of cases in the 3rd and 4th decade of their life. The most common

subtype was luminal B (40.9%) with the maximum number of cases presenting in stage II (53.26%) and with grade II (51.1%). Triple-negative breast cancer was found to be associated with brisk mitosis, lymphovascular invasion (66.67%), necrosis (77.78%), and ductal carcinoma in situ (66.67%). These findings were clinically significant. ($P < 0.05$) Conclusion: The early age of presentation of breast carcinoma in the industrial population would warrant the need to focus on various molecular subtypes and

clinicopathological parameters that may have different prognostic implications in this population. J Crawford, B; Steck, SE; Sandler, DP; Merchant, AT; Woo, JMP;
Park, YMM Crawford, Brittany; Steck, Susan E.;

Sandler, Dale P.; Merchant, Anwar T.; Woo, Jennifer M. P.; Park,
Yong-Moon Mark Dietary patterns, socioeconomic

disparities, and risk of type 2 diabetes in the Sister Study

DIABETES RESEARCH AND CLINICAL PRACTICE English

Article

Type 2 diabetes;

Dietary patterns; Socioeconomic status; Disparities CORONARY-
HEART-DISEASE; HEALTHY EATING INDEX; MEDITERRANEAN DIET;

ADHERENCE; QUALITY; QUESTIONNAIRE; MORTALITY; MELLITUS; VALIDITY;
STROKE Aims: We investigated the role of socioeconomic

disparities in the association between diet and risk of type 2
diabetes (T2D). Methods: We used prospective data from 40,243

Sister Study participants aged 35 to 74 years who were enrolled in
2003-2009. Scores for healthy eating indices (alternate

Mediterranean diet, Dietary Approaches to Stop Hypertension,
alternative Healthy Eating Index, and Healthy Eating Index 2015

(HEI-2015)) were calculated using data from a 110-item food
frequency questionnaire completed at enrollment. Incident T2D was

defined based on self-reported physician's diagnosis or use of
anti-diabetic medications. Multivariable-adjusted hazard ratios

(aHRs) and 95% confidence intervals (CIs) were estimated using Cox
proportional hazards models. Results: We observed inverse

associations between all four dietary indices and incident T2D
after multivariable adjustment. These associations were most

pronounced among women with higher educational attainment, higher
income, and lower area deprivation index (ADI) (e.g., for the HEI-

2015: low ADI, aHR_{Q4vsQ1}: 0.44, 95% CI: 0.35, 0.56 vs high ADI,
aHR_{Q4vsQ1}: 0.75, 95% CI: 0.63, 0.90; pinteraction:

0.0007). Conclusions: Weaker associations among women with lower

socioeconomic status and higher neighborhood deprivation suggests
that other factors play a larger role in T2D incidence than diet

quality among individuals with low SES. Human Papillomavirus (HPV) Infection: Molecular Epidemiology, Genotyping, Seroprevalence and Associated Risk Factors among Arab Women in Qatar PLOS ONE English

Article

EXTENDED

MIDDLE-EAST; CANCER; PREVALENCE; ANTIBODIES; BURDEN Human Papillomavirus (HPV) infections are known to cause cervical cancer worldwide, however, limited information is currently available on prevalence, types distribution and risk factors for HPV infection in the Arab countries. We conducted a cross-sectional observational study exclusively of women of Arabic origin residing in Qatar (n = 406) who were selected from the Women's Hospital at Hamad Medical Corporation (HMC) and Health Centers of the Primary Health Care Corporation in Doha, Qatar over the period March 2013 to August 2014. Socio-demographic, behavioral and clinical data were collected. Four hundred and six cervical smears and 292 blood samples were included in the study. HPV typing was done using HPV type-specific primers-based real-time PCR, and Sanger sequencing. HPV IgG and IgM were quantified using ELISA assays. The prevalence of HPV infection amongst Qatari and non-Qatari Arab women were 9.8% and 6.1%, respectively and 7.6% and 16.7% in women with normal and abnormal cytology, respectively. HPV 81 was the most commonly found genotype in women with normal cytology (34.5%), whereas HPV 81, 16 and 59 in women with abnormal cytology (25.0% each). All the HPV DNA positive women were seronegative and HPV-IgG prevalence was higher in Qatari women than in non-Qatari Arab women. None of the studied factors had any significant association with HPV-DNA positivity or HPV-IgG seropositivity. The overall identified HPV DNA prevalence and HPV seroprevalence among Arab women in Qatar were on the low side compared to global levels.

SKIN-CANCER; MALIGNANT-MELANOMA; CUTANEOUS MELANOMA;
AMERICAN-ACADEMY; TRENDS; MORTALITY; EPIDEMIOLOGY; CLINICS; TIME;
AGE Although no study has definitively shown that unfocused
screening of skin cancer is effective, many campaigns have been
organized with the aim of increasing awareness on melanoma risk
factors. The objective of this study was to analyse the results of
the Skin Cancer Screening Day in Italy during the period 2005-
2007, to determine the priorities for melanoma control plans in a
Mediterranean country. A total of 5002 patients were screened by
dermatologists in 31 cities. Individuals who considered themselves
to have many naevi and those with a family history of melanoma
showed a higher number of common and atypical naevi. Ten
melanomas, 20 basal cell carcinomas and two squamous cell
carcinomas were histopathologically confirmed. Our observations
provide the following suggestions for melanoma prevention
strategies: (a) an unfocused campaign is suitable to inform the

public about the importance of self-examination of the skin, but is not useful to identify a larger number of melanomas; and (b) melanoma screening campaigns should focus on a selected population, which meets rigorous risk criteria to maintain higher cost-effectiveness. The financial support to effective melanoma screening programmes could be increased, especially in southern populations where lower levels of self-surveillance and socioeconomic conditions represent risk factors for late identification of melanoma. Diet Quality and Risk of Melanoma in
an Italian Population JOURNAL OF NUTRITION English

Article diet; diet quality;
dietary patterns; melanoma; case-control study; epidemiology

CORONARY-HEART-DISEASE; HEALTHY EATING INDEX; MEDITERRANEAN
DIET; CUTANEOUS MELANOMA; MALIGNANT-MELANOMA; STOP HYPERTENSION;
COLORECTAL-CANCER; VITAMIN-C; PATTERNS; METAANALYSIS

Background: Some results from laboratory and epidemiologic
studies suggest that diet may influence the risk of melanoma, but
convincing evidence for a role of single nutrients or food items
is lacking. Diet quality, which considers the combined effect of
multiple food items, may be superior for examining this relation.
Objective: We sought to assess whether diet quality, evaluated
with the use of 4 different dietary indexes, is associated with
melanoma risk. Methods: In this population-based case-control
study, we analyzed the relation between 4 diet quality indexes,
the Healthy Eating Index 2010 (HEI-2010), Dietary Approaches to
Stop Hypertension (DASH) index, Greek Mediterranean Index (GMI),
and Italian Mediterranean Index (IMI), and melanoma risk in a
northern Italian community, with the use of data from 380 cases
and 719 matched controls who completed a semiquantitative food
frequency questionnaire. Results: In the overall sample, we found
an inverse association between disease risk and the HEI-2010 and
DASH index, but not the Mediterranean indexes, adjusting for
potential confounders (skin phototype, body mass index, energy

intake, sunburn history, skin sun reaction, and education). However, in sex stratified analyses, the association appeared only in women (P-trend: 0.10 and 0.04 for the HEI-2010 and DASH index, respectively). The inverse relations were stronger in women younger than age 50 y than in older women, for whom the GMI and IMI scores also showed an inverse association with disease risk (P-trend: 0.05 and 0.02, respectively). Conclusions: These results suggest that diet quality may play a role in cutaneous melanoma etiology among women. A New Protein Extract Inhibitor from Hypobranchial Purple Gland of Hexaplex trunculus, a Mediterranean Mollusk, Impairs the Motility of Human Glioblastoma U87 and the HeLa Cell Line of Cervical Carcinoma Cells NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL English Article

BREAST-CANCER; RISK The aim of this study is to evaluate the effect of hypobranchial gland protein extracts (HGPEs) of Hexaplex trunculus on the viability, cell adhesion, and migration of human U87 glioblastoma cells and the HeLa cell line obtained from epithelial cervical carcinoma cells. Analysis of the HGPE on polyacrylamide gel (12%) shows a variety of proteins whose molecular weights vary between 12 and 100 kDa. Chromatographic analysis shows 16 peaks obtained at various retention times. Cytotoxic effect was observed after 24hours of incubation at the concentrations 20, 40, and 60g/ml in a dose-dependent manner. Concentrations giving 50% inhibition (IC50) are 22g/ml for U87 and 15g/ml for HeLa cells. Our results show inhibition of U87 and HeLa cancer cell adhesion at concentrations of 10 and 20 mu g/ml, respectively. High-pressure liquid chromatography fractions did not show antiadhesive effect on both cancer cell lines. The presence of HGPEs completely blocked the migration of the two cancer cell lines at 10 mu g/ml. This inhibition is dose-dependent. IC50 is about 2.5g/ml for both cancer cells. The HGPE of Hexaplex trunculus may have the potential to serve as a model for future anticancer drug development with probably a synergistic activity of the proteins of this extract. third global State of the World's Midwifery report (SoWMy 2021)
provides an updated evidence base on the sexual, reproductive,
maternal, newborn and adolescent health (SRMNAH) workforce. For
the first time, SoWMy includes high-income countries (HICs) as
well as low- and middle-income countries. This paper describes the
similarities and differences between regions and income groups,
and discusses the policy implications of these variations. SoWMy
2021 estimates a global shortage of 900,000 midwives, which is
particularly acute in low-income countries (LICs) and in Africa.
The shortage is projected to improve only slightly by 2030 unless
additional investments are made. The evidence suggests that these
investments would yield important returns, including: more
positive birth experiences, improved health outcomes, and
inclusive and equitable economic growth. Most HICs have sufficient
SRMNAH workers to meet the need for essential interventions, and
their education and regulatory environments tend to be strong.
Upper-middle-income countries also tend to have strong policy
environments. LICs and lower-middle-income countries tend to have
a broader scope of practice for midwives, and many also have
midwives in leadership positions within national government. Key
regional variations include: major midwife shortages in Africa and
South-East Asia but more promising signs of growth in South-East
Asia than in Africa; a strong focus in Africa on professional
midwives (rather than associate professionals: the norm in many
South-East Asian countries); heavy reliance on medical doctors
rather than midwives in the Americas and Eastern Mediterranean
regions and parts of the Western Pacific; and a strong educational
and regulatory environment in Europe but a lack of midwife leaders
at national level. SoWMy 2021 provides stakeholders with the
latest data and information to inform their efforts to build back
better and fairer after COVID-19. This paper provides a number of
policy responses to SoWMy 2021 that are tailored to different
contexts, and suggests a variety of issues to consider in these
contexts. These suggestions are supported by the inclusion of all
countries in the report, because it is clear which countries have
strong SRMNAH workforces and enabling environments and can be
viewed as exemplars within regions and income groups. [Nove,

Prevalence and genotype screening of human papillomavirus among women attending a private hospital in Northern Cyprus: an 11-year retrospective study BMC WOMENS HEALTH
English Article

Human papillomavirus; High-risk HPV; Cervical cancer; Genotyping; Real-time PCR; Cyprus RISK; INFECTION; HPV

Background Human papillomavirus (HPV) is the most common sexually transmitted pathogen both in men and women. Accumulating epidemiological evidence supports a strong association between HPV infection and cancer of the cervix, vulva, vagina, anus, and penis. Currently, data on the HPV prevalence and genotyping is lacking in Northern Cyprus, a region in which HPV vaccination is not freely accessible via the national immunization program. The aim of this study was to evaluate the HPV type-specific prevalence in women with and without cytological abnormalities living in Northern Cyprus. Methods A total of 885 women who presented to the Department of Gynecology and Obstetrics Clinic between January 2011 and December 2022 were included in the study. Samples were collected for cytology. Cervical specimens were investigated for the presence of HPV-DNA and genotyping of HPV was performed using real-time polymerase chain reaction (rtPCR). Cytological examination was interpreted according to the Bethesda system. Results Among all patients, overall high-risk HPV DNA prevalence was 44.3%. HPV-16 and HPV-18 positivity was found in 10.4% and 3.7% of women respectively, while other high-risk HPV (OHR-HPV) was the most frequent type of HPV (30.2%). The highest frequency of HPV infection was observed in the 30-55 age group (51.0%), followed by the < 30 age group (45.7%). Co-infection with two or more HPV types was observed in 17.0% of all positive samples, in which the prevalence of HPV-16 + HPV-18 was 2.3%, HPV-16 + OHR-HPV and HPV-18 + OHR-HPV was 12.0% and 5.1%, respectively. Among the screened patients, 37.5% had abnormal and 62.5% had normal cytology results. HR-HPV positivity was 65.7% and 34.0% in patients with abnormal and normal cytology. The highest incidence of HRC-HPV was OHR-HPV types (44.7%) in positive cytology cases. Among women with a cytology result of ASCUS, L-SIL, H-SIL and unspecified dysplasia, 52.1%, 67.6%, 97.5% and 75.6% were respectively infected with HR-HPV. Conclusion The present study provides the latest epidemiological data related to HPV

prevalence and genotype distribution among women living in Northern Cyprus. Considering the unavailability of free vaccination in the community, it is imperative to implement local HPV screening programs and provide guidelines on HPV prevention and measures during early school education. Alteration in the subcellular location of the inhibitor of growth protein p33(ING1b) in estrogen receptor alpha positive breast carcinoma cells TURKISH JOURNAL OF BIOLOGY

English Article

p33(ING1b); estrogen receptor alpha; invasive breast carcinoma TUMOR-SUPPRESSOR P33(ING1B); NUCLEAR EXPRESSION; GENE FAMILY; DNA-DAMAGE; CANCER; TRANSCRIPTION; SENESCENCE; SHIFT ING1 has regulatory roles in the expression of genes associated with proliferation, apoptosis, and senescence. p33(ING1b) is the most widely expressed isoform of the gene. Downregulation of its nuclear expression is involved in differentiation and pathogenesis in invasive breast carcinoma. Yet the mechanism(s) by which p33 nuclear targeting is regulated remains unknown. In this study, we analyzed human invasive breast carcinoma tissue samples by immunostaining with p33 and correlating p33 location with the presence of ERa. Our findings show the expression of p33 protein in ER alpha-positive tumor samples was in the nucleus alone, while the expression was mainly in the cytoplasm in ERa-negative tumor samples. Examination of the localization of p33 in the nucleus and/or cytoplasm in several different cell lines demonstrated 17 beta-estradiol (E2) treatment causes dramatic compartmental shift in p33 protein from the cytoplasm to the nucleus in ER alpha-positive MDA-66 cells. No significant differences in ER alpha-negative MDA-MB-231 cells in the same conditions were observed. We show for the first time nuclear localization of p33 is regulated by estradiol induction in ER alpha-positive breast cancer cells.

These results suggest compartmental shift in p33 by ER signaling may be an important molecular event in the differentiation and pathogenesis of invasive breast cancer. Physical activity of subjects aged 50-64 years involved in the European Prospective Investigation into Cancer and Nutrition (EPIC) PUBLIC HEALTH NUTRITION English

Article EPIC study; physical activity; activity patterns; recreational activity; home activity Europe BREAST-CANCER; PROSTATE-CANCER; RISK Objective: To describe physical activity of participants in the European Prospective Investigation into Cancer and Nutrition (EPIC). Design: A cross-sectional analysis of baseline data of a European prospective cohort study. Subjects: This analysis was restricted to participants in the age group 50-64 years, which was represented in all EPIC centres. It involved 236 386 participants from 25 centres in nine countries. In each EPIC centre, physical activity was assessed by standardised and validated questions. Frequency distribution of type of professional activity and participation in non-professional activities, and age-adjusted means, medians and percentiles of time dedicated to non-professional activities are presented for men and women from each centre. Results: Professional activity was most frequently classified as sedentary or standing in all centres. There was a wide variation regarding participation in different types of non-

professional activities and time dedicated to these activities across EPIC centres. Over 80% of all EPIC participants engaged in walking, while less than 50% of the subjects participated in sport. Total time dedicated to recreational activities was highest among the Dutch participants and lowest among men from Malmo (Sweden) and women from Naples (Italy). In all centres, total time dedicated to recreational activity in the summer was higher than in the winter. Women from southern Europe spent the most time on housekeeping. Conclusions: There is a considerable variation of physical activity across EPIC centres. This variation was especially evident for recreational activities in both men and women.

Schistosoma mansoni eggs induce Wnt/ β -catenin
signaling and activate the protooncogene c-Jun in human and
hamster colon SCIENTIFIC REPORTS English

Article

COLORECTAL-

CANCER; HEPATIC-FIBROSIS; CYCLIN D1; INFECTION; HOMEOSTASIS;
EXPRESSION; PROGNOSIS; HELMINTHS; COLITIS Schistosomiasis
(bilharzia) is a neglected tropical disease caused by parasitic
flatworms of the genus *Schistosoma*, with considerable morbidity in
parts of the Middle East, South America, Southeast Asia, in sub-
Saharan Africa, and particularly also in Europe. The WHO describes
an increasing global health burden with more than 290 million
people threatened by the disease and a potential to spread into
regions with temperate climates like Corsica, France. The aim of
our study was to investigate the influence of *S. mansoni* infection
on colorectal carcinogenic signaling pathways in vivo and in
vitro. *S. mansoni* infection, soluble egg antigens (SEA) and the
Interleukin-4-inducing principle from *S. mansoni* eggs induce
Wnt/ β -catenin signaling and the protooncogene c-Jun as well as
downstream factor Cyclin D1 and markers for DNA-damage, such as
Parp1 and gamma H2a.x in enterocytes. The presence of these
characteristic hallmarks of colorectal carcinogenesis was
confirmed in colon biopsies from *S. mansoni*-infected patients
demonstrating the clinical relevance of our findings. For the
first time it was shown that *S. mansoni* SEA may be involved in the
induction of colorectal carcinoma-associated signaling pathways.

NCD Risk Factor Collaboration Worldwide trends in hypertension prevalence and progress in treatment and control from 1990 to 2019: a pooled analysis of 1201 population-representative studies with 104 million participants LANCET English Article

BLOOD-PRESSURE; SYSTEMATIC

ANALYSIS; INCOME COUNTRIES; MIDDLE-INCOME; ADULTS; PREVENTION; GUIDELINES; MANAGEMENT; ADHERENCE; DIAGNOSIS Background Hypertension can be detected at the primary health-care level and low-cost treatments can effectively control hypertension. We aimed to measure the prevalence of hypertension and progress in its detection, treatment, and control from 1990 to 2019 for 200 countries and territories. Methods We used data from 1990 to 2019 on people aged 30-79 years from population-representative studies with measurement of blood pressure and data on blood pressure treatment. We defined hypertension as having systolic blood pressure 140 mm Hg or greater, diastolic blood pressure 90 mm Hg or greater, or taking medication for hypertension. We applied a

Bayesian hierarchical model to estimate the prevalence of hypertension and the proportion of people with hypertension who had a previous diagnosis (detection), who were taking medication for hypertension (treatment), and whose hypertension was controlled to below 140/90 mm Hg (control). The model allowed for trends over time to be non-linear and to vary by age. Findings The number of people aged 30-79 years with hypertension doubled from 1990 to 2019, from 331 (95% credible interval 306-359) million women and 317 (292-344) million men in 1990 to 626 (584-668) million women and 652 (604-698) million men in 2019, despite stable global age-standardised prevalence. In 2019, age-standardised hypertension prevalence was lowest in Canada and Peru for both men and women; in Taiwan, South Korea, Japan, and some countries in western Europe including Switzerland, Spain, and the UK for women; and in several low-income and middle-income countries such as Eritrea, Bangladesh, Ethiopia, and Solomon Islands for men. Hypertension prevalence surpassed 50% for women in two countries and men in nine countries, in central and eastern Europe, central Asia, Oceania, and Latin America. Globally, 59% (55-62) of women and 49% (46-52) of men with hypertension reported a previous diagnosis of hypertension in 2019, and 47% (43-51) of women and 38% (35-41) of men were treated. Control rates among people with hypertension in 2019 were 23% (20-27) for women and 18% (16-21) for men. In 2019, treatment and control rates were highest in South Korea, Canada, and Iceland (treatment >70%; control >50%), followed by the USA, Costa Rica, Germany, Portugal, and Taiwan. Treatment rates were less than 25% for women and less than 20% for men in Nepal, Indonesia, and some countries in sub-Saharan Africa and Oceania. Control rates were below 10% for women and men in these countries and for men in some countries in north Africa, central and south Asia, and eastern Europe. Treatment and control rates have improved in most countries since 1990, but we found little change in most countries in sub-Saharan Africa and Oceania. Improvements were largest in high-income countries, central Europe, and some upper-middle-income and recently high-income countries including Costa Rica, Taiwan, Kazakhstan, South Africa, Brazil, Chile, Turkey, and Iran. Interpretation Improvements in the detection, treatment, and control of hypertension have varied substantially across countries, with some middle-income countries now outperforming most high-income nations. The dual approach of reducing hypertension prevalence through primary prevention and enhancing its treatment and control is achievable not only in high-income countries but also in low-income and middle-income settings. Agardh (Ulvophyceae, Caulerpales) is an algae of tropical origin that was accidentally introduced into the Mediterranean in 1984. *Caulerpenyne* (Cau) is the major metabolite present in *Caulerpa taxifolia*. This metabolite has previously been shown to be cytotoxic against cell lines in culture as in KB cells and fibroblasts from hamsters. Cau along with 6 other drugs representative of the major classes of anticancer products was tested against 8 cancer cell lines of human origin. Cau demonstrated growth-inhibitory effects in all cases with some variability between cell lines; this inter-cell variability was, however, less marked than that observed with the anticancer drug tested. Cells of colorectal cancer origin were the most sensitive

to the presence of Cau with IC50 values of 6.1 and 7.7 μ M. Increasing the duration of contact between Cau and the cells from 75 min to 29.5 hr did not improve the cytotoxic efficacy of this compound. When Cau was pre-incubated in the culture medium for from 7 to 83 min before being exposed to CAL 27 cells (head and neck cancer origin), there was a constant loss of cytostatic action of Cau as a function of Cau pre-incubation time. As the bovine serum albumin concentration increased in the culture medium, the concentration-response curves showed a constant shift towards the right, indicating a loss of cytostatic activity of Cau. In the presence of Cau, cells in culture clearly exhibited an early and marked shift into S phase followed by a blockade into the premitotic G2 M phase. Possible targets for CAU remain to be identified. Cau needs to be tested on tumor bearing animals to confirm this promising antiproliferative activity. NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL

English Article

COLORECTAL-CANCER; 15-HYDROXYPROSTAGLANDIN DEHYDROGENASE; MEDITERRANEAN DIET; E SYNTHASE; FISH-OIL; INTERVENTION; PREVENTION; MICE; CYCLOOXYGENASE-1; EICOSANOIDS Prostaglandin E-2 (PGE(2)) in the colon is a pro-inflammatory mediator that is associated with increased risk of colon cancer. In this study, expression of genes in the PGE(2) pathway were quantified in colon biopsies from a trial of a Mediterranean versus a Healthy Eating diet in 113 individuals at high risk for colon cancer. Colon biopsies were obtained before and after 6months of intervention. Quantitative, real-time PCR was used to measure mRNA expression of prostaglandin H synthases (PTGS1 and 2), prostaglandin E synthases (PTGES1 and 3), prostaglandin dehydrogenase (HPGD), and PGE(2) receptors (PTGER2, PTGER4). The most highly expressed genes were HPGD and PTGS1. In multivariate linear regression models of baseline data, both colon saturated fatty acid concentrations and PTGS1 expression were significant, positive predictors of colon PGE(2) concentrations after controlling for nonsteroidal anti-inflammatory drug use, gender, age, and smoking status. The effects of dietary intervention on gene expression were minimal

with small increases in expression noted for PTGES3 in both arms and in PTGER4 in the Mediterranean arm. These results indicate that short-term dietary change had little effect on enzymes in the prostaglandin pathway in the colon and other factors, such as differences in fatty acid metabolism, might be more influential.

GASTROENTEROLOGY English Article

Colon Cancer; Colitis-associated Cancer; Tumor Suppressor; Mouse Model FAMILIAL MEDITERRANEAN FEVER; BOWEL-DISEASE; ULCERATIVE-COLITIS; IFN-GAMMA; ATTENUATES COLITIS; BARRIER FUNCTION; CROHNS-DISEASE; STEM-CELLS; COLON; GENE

BACKGROUND & AIMS: Inflammatory bowel diseases (IBD) increase risk for colorectal cancer. Mutations in the Mediterranean fever gene (MEFV or pyrin) are associated with hereditary autoinflammatory disease and severe IBD. Expression of MEFV, a sensor protein that initiates assembly of the inflammasome complex, is increased in colon biopsies from patients with IBD. We investigated the role of pyrin in intestinal homeostasis in mice. METHODS: Mefv(-/-) mice and C57/BL6 mice (controls) were given azoxymethane followed by multiple rounds of dextran sodium sulfate (DSS) to induce colitis and tumorigenesis. In some experiments, Mefv(-/-) mice were given injections of recombinant interleukin 18 (rIL18) or saline (control) during DSS administration. Colon tissues were collected at different time points during colitis development and analyzed by histology, immunohistochemistry, immunoblots, or ELISAs (to measure cytokines). Spleen and mesenteric lymph node were collected, processed, and analyzed by flow cytometry. Colon epithelial permeability was measured in mice with colitis by gavage of fluorescent dextran and quantification of serum levels. RESULTS: MEFV was expressed in colons of control mice and expression increased during chronic and acute inflammation; high levels were detected in colon tumor and adjacent non-tumor tissues. Mefv(-/-) mice developed more severe colitis than control mice, with a greater extent of epithelial hyperplasia and a larger tumor burden. Levels of inflammatory cytokines (IL6) and chemokines were significantly higher in colons of Mefv-/- mice than control mice following colitis induction, whereas the level IL18, which depends on the inflammasome for maturation and release, was significantly lower in colons of Mefv-/- mice. Mefv-/- mice had increased epithelial permeability following administration of DSS than control mice, and loss of the tight junction proteins occludin and claudin-2 from intercellular junctions. STAT3 was activated (phosphorylated) in inflamed colon tissues from Mefv-/-, which also had increased expression of stem cell markers (OLFM4, BMI1, and MSI1) compared with colons from control mice. Administration of rIL18 to Mefv-/- mice reduced epithelial permeability, intestinal inflammation, the severity of colitis, and colon tumorigenesis. CONCLUSIONS: In studies with DSS-induced colitis, we found that pyrin (MEFV) is required for inflammasome activation and IL18 maturation, which promote intestinal barrier integrity and prevent colon inflammation and tumorigenesis. Strategies to increase activity of MEFV or IL18 might be developed for the treatment of IBD and prevention of colitis-associated tumorigenesis.  Sideritis Perfoliata (Subsp. Perfoliata) Nutritive Value and Its Potential Medicinal Properties ANTIOXIDANTS
 English Article Sideritis perfoliata; wrinkles; Cutibacterium acnes; antimycobacterial; melanin inhibition; antioxidant capacity ESSENTIAL OIL COMPOSITION; B16 MELANOMA-CELLS; ANTIOXIDANT ACTIVITIES; CHEMICAL-COMPOSITION; ANTIMICROBIAL ACTIVITIES; BIOLOGICAL-ACTIVITIES; TYROSINASE; IDENTIFICATION; ANTIBACTERIAL; INHIBITORS Sideritis perfoliata L. subsp. perfoliata is an endemic species of the Eastern Mediterranean region with several uses in traditional medicine. The present study aims to explore the unknown properties of S. perfoliata investigating the nutritional content as well as the antioxidant, anticancer, antituberculosis, antiwrinkle, anti-acne, hyper/hypo-pigmentation and antibacterial activities. Mineral content, nutritional value, the composition and antioxidant properties of the essential oil, the antityrosinase, the antibacterial activity and anti-elastase potential of the extract, were evaluated. The antiproliferative activity of S. perfoliata against cervical cancer (HeLa), human melanoma (UCT-Mel-1), human hepatocellular carcinoma (HepG2) and human epidermoid carcinoma (A431) was investigated. Cytotoxic effects on normal human keratinocyte (HaCat) and kidney epithelial (Vero) cell lines were also determined. Sideritis perfoliata exhibited high nutritional value of proteins and minerals (K, P, Mg, Fe, Zn, Cu). The most abundant components of the essential oil were found

to be alpha-pinene, beta-phelladrene, valeranone, beta-pinene and sabinene. The ethanolic extract of *S. perfoliata* displayed moderate antioxidant potential and antibacterial activity against *Prevotella intermedia*. Noteworthy elastase and moderate anticancer potential against the human liver cancer cell line (HepG2) was observed with IC50 values of 57.18 $\pm$ 3.22 μ g/mL and 64.27 $\pm$ 2.04 μ g/mL respectively. The noteworthy in vitro activity of *S. perfoliata* could be due to the presence of flavonoids and phenols in the leaves, having high nutritional value. *Sideritis perfoliata* could potentially be useful to reduce the appearance of wrinkles and for the treatment of liver cancer. The moderate antibacterial, antioxidant and elastase activity of the plant can be linked to the traditional use of *S. perfoliata* for the treatment of wounds and inflammation.

 Vuko, Elma; Dunkic, Valerija; Maravic, Ana; Ruscic, Mirko; Nazlic, Marija; Radan, Mila; Ljubenkovic, Ivica; Soldo, Barbara; Fredotovic, Zeljana Not Only a Weed Plant-Biological Activities of Essential Oil and Hydrosol of *Dittrichia viscosa* (L.) Greuter PLANTS-BASEL English Article
Dittrichia viscosa; essential oil; hydrosol; GSH; antimicrobial; antiproliferative; antiphytoviral activity INULA-VISCOSA; ANTIPHYTOVIRAL ACTIVITY; PROTOCATECHUIC ACID; ANTIBACTERIAL ACTIVITY; CHEMICAL-COMPOSITION; PHENOLIC-COMPOUNDS; CANCER-CELLS; HUMAN BREAST; IN-VITRO; APOPTOSIS With the increasing interest in obtaining biologically active compounds from natural sources, *Dittrichia viscosa* (L.) Greuter (Asteraceae) came into our focus as a readily available and aromatic wild shrub widely distributed in the Mediterranean region. This work provides a phytochemical profile of *D. viscosa* in terms of parallel chemical composition in the lipophilic fraction (essential oil) and the water fraction (hydrosol). GC-MS analysis identified 1,8-cineole, caryophyllene oxide, alpha-terpenyl acetate, and alpha-muurolol as the major components of the essential oil, while in the hydrosol p-menth-1-en-9-ol, 1,8-cineole, linalool, cis-sabinene hydrate, and alpha-muurolol were the major volatile components. 3,4-Dihydroxybenzoic acid was found to be the predominant compound in the hydrosol composition by HPLC analysis. The antimicrobial potential of both extracts was evaluated against thirteen opportunistic pathogens associated with common skin and wound infections and emerging food spoilage microorganisms. The antimicrobial activity of the essential oil suggests that the volatiles of *D. viscosa* could be used as novel antimicrobial agents. The antiproliferative results of *D. viscosa* volatiles are also new findings, which showed promising activity against three cancer cell lines: HeLa (cervical cancer cell line), HCT116 (human colon cancer cell line), and U2OS (human osteosarcoma cell line). The decrease in GSH level observed in hydrosol-treated HeLa cells suggests oxidative stress as a possible mechanism of the antiproliferative effect of hydrosol on tumor cells. The presented results are also the first report of significant antiphytoviral activity of hydrosol against tobacco mosaic virus (TMV) infection. Based on the results, *D. viscosa* might have the potential to be used in crop protection, as a natural disinfectant and natural anticancer agent.  The Polyphenolic Composition of Extracts Derived from Different Greek Extra Virgin Olive Oils Is Correlated with Their Antioxidant Potency OXIDATIVE MEDICINE AND CELLULAR LONGEVITY
 English Article
 Olive oil possesses a predominant role in the diet of countries around the Mediterranean basin, whereas it is a known constituent of several sectors of human culture. The polyphenolic composition of olive oil seems to be a key factor in its beneficial biological properties. Based on the above, the aim of this study was to correlate the polyphenolic composition of five extracts derived from a Greek olive oil variety with their antioxidant potency and antimutagenic activities in vitro with chemical-based techniques and cell culture-based assays. According to the results obtained, the polyphenol samples with higher concentration of hydroxytyrosol (HT) were more potent in antioxidant and antimutagenic activity in vitro, as indicated by their ability to scavenge ABTS(center dot+)radical and to protect the strand of plasmid DNA from free radical-induced breaking compared to the corresponding samples with higher levels of tyrosol (T) and its derivatives. However, this observation was not evident in the cell culture model (i.e., the HeLa cervical cancer cell line) to which the tested extracts were administered. Specifically, the T-rich extracts more effectively increased endogenous GSH levels measured by flow cytometry than did the HT-rich compounds. Also, olive oil compounds contributed variously to the expression of genes implicated in the cell antioxidant machinery, as indicated by quantitative PCR. Therefore, the relationship between structure and function in redox regulation is complex and merits the combination of tests. Given that factors like the production and storage regimen of the plants are major determinants of the composition of the generated extracts, we propose that specific conditions should be adopted in order to achieve their maximum biological activity. These results followed by others in the same direction could provide a solid basis for the production of functional foods enriched in olive oil extracts with potential antioxidant action in vivo. J Smith, JS; Robinson, NJ Smith, JS; Robinson, NJ Age-specific prevalence of infection with herpes simplex virus types 2 and 1: A global review JOURNAL OF INFECTIOUS DISEASES English Article; Proceedings Paper Symposium on Extending the Boundaries of Herpesvirus Infections - Recognizing the Role of Valacyclovir NOV, 2000 MALTA SEXUALLY-TRANSMITTED-DISEASES; HUMAN-IMMUNODEFICIENCY-VIRUS; HUMAN-PAPILLOMAVIRUS TYPE-16; LOW-INCOME NEIGHBORHOODS; GENITAL-ULCER-DISEASE; FEMALE SEX WORKERS; RISK-FACTORS; PREGNANT-WOMEN; HIV-INFECTION; CERVICAL-CANCER

Information on age- and sex-specific prevalence of herpes simplex virus (HSV) types 2 and 1 infections is essential to optimize genital herpes control strategies, which increase in importance because accumulating data indicate that HSV-2 infection may increase acquisition and transmission of human immunodeficiency virus. This review summarizes data from peer-reviewed publications of type-specific HSV seroepidemiologic surveys. HSV-2 prevalence is, in general, highest in Africa and the Americas, lower in western and southern Europe than in northern Europe and North America, and lowest in Asia. HSV-2 and -1 prevalence, overall and by age, varies markedly by country, region within country, and population subgroup. Age-specific HSV-2 prevalence is usually higher in women than men and in populations with higher risk sexual behavior. HSV-2 prevalence has increased in the United States but national data from other countries are unavailable. HSV-1 infection is acquired during childhood and adolescence and is markedly more widespread than HSV-2 infection. Further studies are needed in many geographic areas. Int Agcy

Recurrent gross mutations of the PTEN tumor
suppressor gene in breast cancers with deficient DSB repair

NATURE GENETICS English Article

CELL-LINES; PROSTATE-CANCER; BRCA1;
INSTABILITY; PHENOTYPE; CARCINOMA; PATTERNS; SUBTYPES; MICE

Basal-like breast cancer (BBC) is a subtype of breast cancer
with poor prognosis(1 - 3). Inherited mutations of BRCA1, a cancer
susceptibility gene involved in double-strand DNA break (DSB)
repair, lead to breast cancers that are nearly always of the BBC
subtype(3 - 5); however, the precise molecular lesions and
oncogenic consequences of BRCA1 dysfunction are poorly understood.
Here we show that heterozygous inactivation of the tumor
suppressor gene Pten leads to the formation of basal-like mammary
tumors in mice, and that loss of PTEN expression is significantly
associated with the BBC subtype in human sporadic and BRCA1-
associated hereditary breast cancers. In addition, we identify
frequent gross PTEN mutations, involving intragenic chromosome
breaks, inversions, deletions and micro copy number aberrations,
specifically in BRCA1-deficient tumors. These data provide an
example of a specific and recurrent oncogenic consequence of
BRCA1-dependent dysfunction in DNA repair and provide insight into
the pathogenesis of BBC with therapeutic implications. These
findings also argue that obtaining an accurate census of genes
mutated in cancer will require a systematic examination for gross
gene rearrangements, particularly in tumors with deficient DSB
repair. [Saal, Lao H.] Columbia Univ, Coll Phys & Surg, New

J Gajate, C; An, F; Mollinedo, F Gajate, C; An, F; Mollinedo, F Rapid and selective apoptosis in human leukemic cells induced by aplidine through a fas/CD95-and mitochondrial-mediated mechanism CLINICAL CANCER RESEARCH

English Article

ANTIPROLIFERATIVE AGENT DIDEMNIN; ETHER PHOSPHOLIPID ET-18-OCH3; CYTOCHROME-C RELEASE; TERMINAL KINASE JNK; HUMAN HEPATOCYTES; PROTEIN-KINASE; CLINICAL-TRIAL; CANCER-CELLS; TUMOR-CELLS; INDUCTION Aplidine is a promising antitumor agent derived from the Mediterranean tunicate *Aplidium albicans*. We have found that Aplidine at nM concentrations (10-100 nM) induced apoptosis

in human leukemic cell lines and primary leukemic cell cultures from leukemic patients. Inhibition of the Fas (CD95)/Fas ligand (CD95L) signaling pathway with an antagonistic anti-Fas antibody partially inhibited Aplidine-induced apoptosis. L929 cells were resistant to Aplidine action but underwent apoptosis after transfection with human Fas cDNA. Aplidine induced a rapid and sustained c-Jun NH2-terminal kinase activation, and pretreatment with curcumin or SP600125 inhibited Aplidine-induced c-Jun NH2-terminal kinase activation and apoptosis. However, inhibition of extracellular signal-regulated kinase and p38 kinase signaling pathways did not affect Aplidine-induced apoptosis. Aplidine induced caspase-3 activation, and caspase inhibition prevented Aplidine-induced apoptosis. Aplidine failed to induce apoptosis in MCF-7 breast cancer cells, defective in caspase-3, additionally implicating caspase-3 in its proapoptotic action. Aplidine also triggered an early release of cytochrome c from mitochondria, and overexpression of bcl-2 by gene transfer abrogated mitochondrial cytochrome c release and apoptosis. Aplidine rapidly induced cleavage of Bid, a mediator that connects the Fas/CD95 cell death receptor to the mitochondrial apoptosis pathway. Primary cultures of normal human cells, including hepatocytes and resting peripheral blood lymphocytes, were spared or weakly affected after Aplidine treatment. Nevertheless, mitogen (phytohemagglutinin/interleukin-2)-activated T lymphocytes resulted sensitively to the apoptotic action of Aplidine. Thus, Aplidine is an extremely potent and rapid apoptotic inducer on leukemic cells that triggers Fas/CD95- and mitochondrial-mediated apoptotic signaling routes, and shows a rather selective apoptotic action on cancer cells and activated T cells. Mental and neurological health research priorities setting
 in developing countries SOCIAL PSYCHIATRY AND PSYCHIATRIC
 EPIDEMIOLOGY English Article

Health research; Developing countries; The combined matrix approach LOW-INCOME A multi-region consultation process designed to generate locally produced regional and global research priorities on mental and neurological health in low- and middle-income countries. Between 2003 and 2005, priority setting exercises on MNH research, using the systematic combined approach matrix (CAM) were held in the six regions of the developing world. One regional meeting per region was convened, and a global meeting was organized before and after the regional exercises. During regional meetings, regional agendas were created listing both research priorities and local problems in MNH. During global meetings, a global research agenda was established and four crucial areas of research priorities were identified: awareness and advocacy, enhancement of research capacity, training for service delivery, and development of evidence based policy. The combined matrix approach enabled the development of regional and global MNH research agendas, derived from bottom up consultations within and between low- and middle-income countries. Collaboration between regions with similar priorities was instituted. Such research agendas are designed to assist policy-makers and donors in the allocation of scarce resources, but they require regular review to reflect changing needs.  ACID; ARTEMISIA-ANNUA; GROWING WILD; L.; CONSTITUENTS; CAPACITY

Thymus longicaulis C. Presl. (Lamiaceae) is a small aromatic
 perennial herb typical of the Illyric-Mediterranean flora,
 traditionally used as remedy for cold, flu, cough, nephritis and
 abdominal pain. In order to carry out a thorough chemical and
 biological screening of the plant and to explore phenophases
 influence on its polyphenol content, samples of the plant were
 collected at different phases during its life cycle (July/October
 2012 and January/April 2013). Each sample, previously extracted
 using a hydroalcoholic solution, was phytochemically analyzed for
 its metabolic constitution applying LC-DAD-ESI-MS/MS techniques.
 Although identified metabolites were differently concentrated at
 the various collection times, T. longicaulis leaf extracts were
 mainly constituted by low molecular weight phenols, and
 flavonoids. Rosmarinic acid was found as the main metabolite in
 Oct12 sample. Chemopreventive efficacy of the investigated
 extracts, by means of their anti-inflammatory, cytotoxic and
 antioxidant activities, was assessed. To this purpose, each
 extract underwent an extensive screening towards five human cell
 lines: CCRF-CEM (leukemia); U251 (glioblastoma); MDA-MB-231
 (breast cancer); HCT-116 (colon cancer) and MRC-5 (lung
 fibroblasts) through XTT (2,3bis(2-methoxy-4-nitro-5-sulphophenyl)-
 5-[(phenylamino)carbonyl]-2H tetrazolium hydroxide) test. The
 ability of the extracts to counteract cyclooxygenase-2 (COX-2)
 expression was also evaluated by COX-2 expression assay in human
 THP-1 monocyte-derived macrophages. COX-2 inhibition could
 represent a valuable anticancer strategy as it is associated with
 carcinogenesis and over-expressed in a variety of human
 malignancies. Oct12 extract, which was particularly rich in
 rosmarinic acid and methylapigenin, exhibited a strong antioxidant
 and anti-inflammatory effectiveness. (C) 2014 Elsevier Ltd. All

diversity of disease-associated loci in Turkish population
JOURNAL OF HUMAN GENETICS English Article

BREAST-CANCER; FREQUENCY;
SELECTION; GENOME; RARE; POLYMORPHISMS; TUBERCULOSIS; VARIANTS;
EUROPE; MTHFR Many consortia and international projects have investigated the human genetic variation of a large number of ethno-geographic groups. However, populations with peculiar genetic features, such as the Turkish population, are still absent in publically available datasets. To explore the genetic predisposition to health-related traits of the Turkish population, we analyzed 34 genes associated with different health-related traits (for example, lipid metabolism, cardio-vascular diseases, hormone metabolism, cellular detoxification, aging and energy metabolism). We observed relevant differences between the Turkish population and populations with non-European ancestries (that is, Africa and East Asia) in some of the investigated genes (that is, AGT, APOE, CYP1B1, GNB3, IL10, IL6, LIPC and PON1). As most complex traits are highly polygenic, we developed polygenic scores associated with different health-related traits to explore the genetic diversity of the Turkish population with respect to other human groups. This approach showed significant differences between the Turkish population and populations with non-European ancestries, as well as between Turkish and Northern European individuals. This last finding is in agreement with the genetic structure of European and Middle East populations, and may also agree with epidemiological evidences about the health disparities of Turkish communities in Northern European countries. Fadhlouli-Zid, Karima; Martinez-Cruz, Begona; Khodjet-el-khil, Houssein; Mendizabal, Isabel; Benammar-Elgaaied, Amel; Comas, David Genetic Structure of Tunisian Ethnic Groups Revealed by Paternal Lineages AMERICAN JOURNAL OF PHYSICAL ANTHROPOLOGY English Article

Tunisia; Berbers; Andalusians; binary markers; SNP; STR; Y-chromosome haplogroups; Y-chromosome phylogeography; human population genetics HUMAN Y-CHROMOSOME; HIGH-RESOLUTION ANALYSIS; NORTH-AFRICA; IBERIAN PENINSULA; STR HAPLOTYPES; NORTHWESTERN AFRICA; MEDITERRANEAN AREA; HUMAN-POPULATIONS; SOUTHERN TUNISIA; MIGRATORY EVENTS Tunisia has experienced a variety of human migrations that have modeled the myriad cultural groups inhabiting the area. Both Arabic and Berber-speaking populations live in Tunisia. Berbers are commonly considered as in situ descendants of peoples who settled roughly in Palaeolithic times, and posterior demographic events such as the arrival of the Neolithic, the Arab migrations, and the expulsion of the "Moors" from Spain, had a strong cultural influence. Nonetheless, the genetic structure and the population relationships of the ethnic groups living in Tunisia have been poorly assessed. In order to gain insight into the paternal genetic landscape and population structure, more than 40 Y-chromosome single nucleotide polymorphisms and 17 short tandem repeats were analyzed in five Tunisian ethnic groups (three Berber-speaking isolates, one Andalusian, and one Cosmopolitan Arab). The most common lineage was the North African haplogroup E-M81 (71%), being fixed in two Berber samples (Chenini-Douiret and Jradou), suggesting isolation and genetic drift. Differential levels of paternal gene flow from the Near East were detected in

the Tunisian samples (J-M267 lineage over 30%); however, no major sub-Saharan African or European influence was found. This result contrasts with the high amount of sub-Saharan and Eurasian maternal lineages previously described in Tunisia. Overall, our results reveal a certain genetic inter-population diversity, especially among Berber groups, and sexual asymmetry, paternal lineages being mostly of autochthonous origin. In addition, Andalusians, who are supposed to be migrants from southern Spain, do not exhibit any substantial contribution of European lineages, suggesting a North African origin for this ethnic group. *Am J Phys Anthropol* 146:271-280, 2011. The effect of HLA-DP gene polymorphisms in Plasmodium
Vivax-induced malaria susceptibility NUCLEOSIDES NUCLEOTIDES &
NUCLEIC ACIDS English Article
Plasmodium vivax; HLA polymorphisms; malaria
GENOME-WIDE ASSOCIATION; CHRONIC HEPATITIS-B; CLASS-II;
MOLECULAR ANALYSIS; DENDRITIC CELLS; VIRUS INFECTION; CERVICAL-
CANCER; RISK; VARIANTS; CLEARANCE Plasmodium vivax is the second
most common Plasmodium parasite causing clinically serious
symptoms and death from malaria. It is an important cause of
morbidity and mortality, especially in Asia, the Middle East, and
South America. Human leukocyte antigen molecules are responsible
for presenting foreign antigens to T cells. Polymorphisms in HLA
genes affect antigen presentation. HLA alleles involved in the
presentation of P. vivax antigens affect the antibody response.
The present study aimed to reveal the relationship of rs3077 and
rs9277535 polymorphisms in HLA-DP genes with malaria caused by P.
vivax for the first time in the worldwide. In the present
research, rs3077 and rs9277535 polymorphisms were investigated in
a case-control study of 124 patients with P. vivax-induced malaria
and 211 healthy persons by using a real-time polymerase chain
reaction (RT-PCR). The results showed that the G alleles of rs3077
and rs9277535 polymorphisms were detected as protective alleles,
while the A alleles of both polymorphisms increase the risk of
susceptibility to malaria disease. The results of the present
study showed that both polymorphisms have a major effect on the
susceptibility to malaria caused by P. vivax. We recommend that
this study should be conducted in a different population with a
larger sample size to confirm our results. [Akgollu, Ersin] Agri

Chemoprevention by Pomegranate: Laboratory and Clinical Evidence
NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL
English Article; Proceedings Paper 1st International
Congress on Nutrition and Cancer MAY 19-23, 2008 Antalya, TURKEY
HUMAN EPIDERMAL-KERATINOCYTES; GRANATUM
FRUIT EXTRACTS; HUMAN BREAST-CANCER; PROSTATE-CANCER; PUNICA-

GRANATUM; ANTIOXIDANT ACTIVITIES; ELLAGIC ACID; IN-VITRO; SEED OIL; KAPPA-B Pomegranate fruit from the tree Punica granatum has been dubbed as the "nature's power fruit." Dating back to Biblical times, the tree itself is attributed to possess extraordinary medicinal properties. The geographical distribution of the tree, being native to the Middle East and some Asian countries, is generally attributed to a lack of interest in its medicinal properties by many western scientists. However, the unique biochemical composition of the pomegranate fruit being rich in antioxidant tannins and flavonoids has recently drawn attention of many investigators to study its exceptional healing qualities. Recent research has shown that pomegranate extracts selectively inhibit the growth of breast, prostate, colon and lung cancer cells in culture. In preclinical animal studies, oral consumption of pomegranate extract inhibited growth of lung, skin, colon and prostate tumors. An initial phase II clinical trial of pomegranate juice in patients with prostate cancer reported significant prolongation of prostate specific antigen doubling time. This review focuses on recent investigations into the effects of pomegranate fruit on cancer. Statistical analysis of human microarray data shows that dietary intervention with n-3 fatty acids, flavonoids and resveratrol enriches for immune response and disease pathways

BRITISH JOURNAL OF NUTRITION English Article Flavonoids; Functional foods; Genome-wide association studies; n-3 Fatty acids; Resveratrol CELL-CYCLE ARREST; JUICE POWDER CONCENTRATE; GENE-EXPRESSION PROFILES; DOUBLE-BLIND; ENCAPSULATED FRUIT; MEDITERRANEAN DIET; HUMAN HEALTH; IN-VITRO; SUPPLEMENTATION; NUTRITION n-3 Fatty acids, flavonoids and resveratrol are well publicised for their beneficial effects on human health and wellbeing. Identifying

common, underlying biological mechanisms targeted by these functional foods would therefore be informative for the public health sector for advising on nutritional health and disease, food and drug product development and consumer interest. The aim of this study was to explore the potential effects of gene expression changes associated with n-3 fatty acids EPA and DHA, flavonoids and resveratrol on modifying biological systems and disease pathways. To test this, publicly available human microarray data for significant gene expression changes associated with dietary intervention with EPA/DHA, flavonoids and resveratrol was subjected to pathway analysis and significance testing for overlap with signals from genome-wide association studies (GWAS) for common non-communicable diseases and biological functions. There was an enrichment of genes implicated in immune responses and disease pathways which was common to all of the treatment conditions tested. Analysis of biological functions and disease pathways indicated anti-tumorigenic properties for EPA/DHA. In line with this, significance testing of the intersection of genes associated with these functional foods and GWAS hits for common biological functions (ageing and cognition) and non-communicable diseases (breast cancer, CVD, diabetes, neurodegeneration and psychiatric disorders) identified significant overlap between the EPA/DHA and breast cancer gene sets. Dietary intervention with EPA/DHA, flavonoids and resveratrol can target important biological and disease pathways suggesting a potentially important role for these bioactive compounds in the prevention and treatment of dietary-related diseases.  FPOS by using a questionnaire covering (i) characteristics of the
 society; (ii) characteristics of the national health care system;
 (iii) level of implementation of psycho-oncology; and (iv) main
 problems of psycho-oncology in the country. ResultsTwenty-six
 (90%) FPOS returned the questionnaires. One-third reported to have
 links with and support from their government, while almost all had
 links with other scientific societies. The FPOS varied in their
 composition of members' professions. Psychosocial care provision
 was covered by state-funded health services in a minority of
 countries. Disparities between countries arose from different
 causes and were problematic in some parts of the world (eg, Africa
 and SE Asia). Elsewhere (eg, Southern Europe and Eastern Europe),
 austerity policies were reportedly responsible for resource
 shortages with negative consequences on psychosocial cancer care.
 Half of FPOS rated themselves to be integrated into mainstream
 provision of care, although lack of funding was the most common
 complain. ConclusionsThe development and implementation of psycho-
 oncology is fragmented and undeveloped, particularly in some parts
 of the world. More effort is needed at national level by strong
 coalitions with oncology societies, better national research
 initiatives, cancer plans, and patient advocacy, as well as by
 stronger partnership with international organizations (eg, World
 Health Organization and Union for International Cancer Control).

Y.; Mohamed, Tarik A.; Hegazy, Mohamed-Elamir F.; Tadros, Soad H.;
Fathallah, Noha Chemical composition and antifungal
activity of *Teucrium Leucocladum* Boiss. essential oils growing in
Egypt using two different techniques FUTURE JOURNAL OF
PHARMACEUTICAL SCIENCES English Article
Essential oil; GC/MS; *Candida*
albicans; Cytotoxic activity; Molecular docking N-
MYRISTOYLTRANSFERASE; ANTIMICROBIAL ACTIVITY; ALPHA-BISABOLOL;
CANCER Background *Teucrium Leucocladum* Boiss. (TL) (family
Lamiaceae), indigenous to Sinai, Egypt, and Mediterranean region,
is considered a rich source of essential oils (EOs). This study
aimed to extract the aerial parts essential oils utilizing hydro-
distillation (HD) and microwave-assisted extraction (MAE), and
analyze the volatile constituents by Gas Chromatography-Mass
Spectrometry (GC/MS). The antifungal and cytotoxic potentials
against *Candida albicans* (*C. albicans*) and non-small cell lung
adenocarcinoma A549, triple-negative breast cancer MDA-MB-231 cell
lines, respectively, were likewise estimated. Subsequently, the
three main compounds were docked into the crystal structure of
Candida albicans N-myristoyltransferase (NMT) with myristoyl-CoA
and peptidic inhibitor (PDB 1IYK), and predictions of human
absorption, distribution, metabolism, and excretion (ADME) were
performed to assess the drug-likeness of the compounds. Results
The chemical profile consisted of monoterpene hydrocarbons,
oxygenated monoterpenes, sesquiterpene hydrocarbons, and
oxygenated sesquiterpenes. The MAE oil sample (TLM) yield was
found to be double that of the HD oil sample (TLH). TLM afforded
an inhibitory diameter (13 mm) comparable to the ketoconazole (20
mm), TLM 100 mg/mL showed the strongest antifungal potential
against *C. albicans*. The cytotoxic assay revealed moderate
activity against A549 and MDA-MB-231. In silico studies using
molecular docking were processed on the major components in which
nerolidol had the best-fitting energy to inhibit *C. albicans* (-
7.21 kcal/mol), while ADME results established a promising first
step for the potential drug bioavailability. Conclusion In this
research, essential oil acquired from the aerial parts proved to
contain monoterpenes and sesquiterpenes, which are classes of
compounds known for their versatile usage in medicine. In vivo
studies on *Teucrium Leucocladum* Boiss. active metabolites against
clinical strains of fungi need to be further studied, as do the
effects of combining the active compounds with antifungal agents
to combat antimicrobial resistance. [Salah, Eman Mohamed;

Bayrac, Abdullah Tahir; Akca, Oya Ercan; Eyidogan, Fusun Inci; Oktem, Huseyin Avni Target-specific delivery of doxorubicin to human glioblastoma cell line via ssDNA aptamer JOURNAL OF BIOSCIENCES English Article

A-172; aptamer; doxorubicin; glioblastoma; GMT-3; XTT DRUG-DELIVERY; CANCER-CELLS; NANOPARTICLES; CHEMOTHERAPY; MULTIFORME; THERAPY; NANOCARRIERS; PLATFORM; PEPTIDE; SYSTEMS Targeted drug delivery approaches have been implementing significant therapeutic gain for cancer treatment since last decades. Aptamers are one of the mostly used and highly selective targeting agents for cancer cells. Herein, we address a nano-sized targeted drug delivery approach adorned with A-172 glioblastoma cell-line-specific single stranded DNA (ssDNA) aptamer in which the chemotherapeutic agent Doxorubicin (DOX) had been conjugated. DNA aptamer, GMT-3, was previously selected for specific recognition of glioblastoma and represented many advantageous characteristics for drug targeting purposes. Flow cytometry analysis proved the binding efficiency of the specific aptamer to tumour cell lines. Cell-type-specific toxicity of GMT-3:DOX complex was showed by XTT assay and terminated cytotoxic effects were screened for both target cell and a control breast cancer cell line. The result of this contribution demonstrated the potential utility of GMT-3 aptamer-mediated therapeutic drug transportation in the treatment of gliomas specifically. It was concluded that aptamer-mediated drug delivery can be applied successfully for clinical use. [Bayrac, Abdullah Tahir]

J Kravitz, ES; Carroll, RJ Kravitz, Eli
S.; Carroll, Raymond J. Re-evaluating composite
scores: Adaptive Lasso variable selection for non-linear models
STAT English Article
adaptive lasso; composite scores; least squares
approximation; non-linear regression; nutritional epidemiology
MEDITERRANEAN DIET; RISK In nutrition, epidemiology, and
other public health fields, composite scores are a common tool
used to assess a health behaviour. These composite scores compare
an individual's health behaviour to an idealized standard and
provide a number, often between 0 and 100, to indicate their
compliance to a health behaviour. Crucially, this measure of
health behaviour is applied across populations (gender, smoking
status, etc.) and health outcomes (colon cancer, breast cancer,
etc.) to create a single interpretable score. One such composite
score is the 2005 Healthy Eating Index that breaks diet into 12
components and evaluates nutritional intake by adherence to these
components. We provide a general method that can be used to
reassess the importance of these 12 components using flexible non-
linear models, across populations and diseases, based on an
asymptotic least squares approximation. We establish oracle
properties of this variable selection technique in our context,
which is different from the usual one population and one disease
context. Although our methods are motivated by the Healthy Eating
Index, they are broad enough to be applied to any composite score
and a broad range of non-linear models. [Kravitz, Eli S.; Carroll,

Reprograms Cancer Cells Toward a More Mesenchymal Niche ADVANCED
BIOSYSTEMS English Article

bioreactors; circulating tumor cells; epithelial to
mesenchymal transition; fluidics; programming; shear force

ADAPTIVE-RESPONSE GENE; TUMOR-CELLS; SHEAR-FLOW; TGF-BETA;
IN-VIVO; ADHESION; MIGRATION; INVASION; MATRIX; CD44 Cancer is
a complex and heterogeneous disease, and cancer cells dynamically
interact with the mechanical microenvironment such as hydrostatic
pressure, fluid shear, and interstitial flow. These factors play
an essential role in cell fate and circulating tumor cell
heterogeneity, and can influence the cellular phenotype. In this
study, a peristaltic continuous flow reactor is designed and
applied to HCT-116 colorectal carcinoma cells to mimic the fluid
dynamics of circulation. With this intervention, a CD44/CD24-cell
subpopulation emerges, and 100 genes are significantly regulated.
The expression of cells at 4 h in the flow reactor is very similar
to TGF-ss treatment, which is an inducer of epithelial-mesenchymal
transition. ATF3 and SERPINE1 are significantly upregulated in
these groups, suggesting that the mesenchymal transition is
induced through this signaling pathway. This flow reactor model is
satisfactory on its own to reprogram colorectal cancer cells
toward a more mesenchymal niche mimicking circulation of the
blood. [Calamak, Semih; Ermis, Menekse; Demirci, Utkan]

incidence of Human Papillomaviruses and Epstein-Barr Virus Is Associated With High to Intermediate Tumor Grade in Human Head and Neck Cancer in Syria FRONTIERS IN ONCOLOGY English

Article head and neck

cancers; human papillomaviruses; Epstein-Barr virus; tumor grade; Syrian population EPITHELIAL-MESENCHYMAL TRANSITION; RISK HUMAN PAPILLOMAVIRUSES; NASOPHARYNGEAL CARCINOMA; BREAST-CANCER; HPV-DNA; EXPRESSION; EBV; LATENT; WOMEN; SENSITIVITY High-risk human papillomaviruses (high-risk HPVs) have been recently reported to be co-present with Epstein-Barr virus (EBV) in different types of human cancers including head and neck (HN), where they can cooperate in the initiation and/or progression of this cancer. Accordingly, we herein explored the prevalence of high-risk HPVs and EBV in 80 HN cancer tissues from the Syrian population using polymerase chain reaction, immunohistochemistry, and tissue microarray methodologies. We report that high-risk HPVs and EBV are present in 35/80 (43.7%) and 41/80 (51.2%) of our samples, respectively, and the most frequent HPV types are 33, 16, 18, 45, 52, 58, 35, 51, and 31, in this order. More significantly, our data reveal that 25/80 (31.2%) of cancer cases are positive for high-risk HPVs as well as EBV, and their co-presence is associated with high/intermediate-grade squamous cell carcinomas. These data confirm the co-presence of high-risk HPVs and EBV in HN cancers in the Syrian population of the Middle East and demonstrate that their co-incidence is linked to a more aggressive cancer phenotype. Thus, future studies are required to confirm these data and elucidate the exact role of high-risk and EBV cooperation in human HN carcinogenesis. J Muyan, M; G  p  r, G; Yasar, P; Ayaz, G; User, SD; Kazan, HH; Huang, YF Muyan, Mesut; Gupur, Gizem; Yasar, Pelin; Ayaz, Gamze; User, Sirma Damla; Kazan, Hasan Huseyin; Huang, Yanfang Modulation of Estrogen Response Element-Driven Gene Expressions and Cellular Proliferation with Polar Directions by Designer Transcription Regulators PLOS ONE English Article

HUMAN-BREAST-CANCER; ZINC-FINGER PROTEINS; RECEPTOR-ALPHA; ER-ALPHA; ACTIVATION FUNCTIONS; REPRESSION; ESTRADIOL; BINDING; DOMAIN; CELLS Estrogen receptor α (ER α), as a ligand-dependent transcription factor, mediates 17 β -estradiol (E2) effects. ER α is a modular protein containing a DNA binding domain (DBD) and transcription activation domains (AD) located at the amino- and carboxyl-termini. The interaction of the E2-activated ER α dimer with estrogen response elements (EREs) of genes constitutes the initial step in the ERE-dependent signaling pathway necessary for alterations of cellular features. We previously constructed monomeric transcription activators, or monotransactivators, assembled from an engineered ERE-binding module (EBM) using the ER α -DBD and constitutively active ADs from other transcription factors. Monotransactivators modulated cell proliferation by activating and repressing ERE-driven gene expressions that simulate responses observed with E2-ER α . We reasoned here that integration of potent heterologous repression domains (RDs) into EBM could generate monotransrepressors that alter ERE-bearing gene expressions and cellular proliferation in directions opposite to those observed with E2-ER α or monotransactivators. Consistent with this, monotransrepressors suppressed reporter gene expressions that emulate the ERE-dependent signaling pathway. Moreover, a model monotransrepressor regulated DNA synthesis, cell cycle progression and proliferation of recombinant adenovirus infected ER-negative cells through decreasing as well as increasing gene expressions with polar directions compared with E2-ER α or monotransactivator. Our results indicate that an 'activator' or a 'repressor' possesses both transcription activating/enhancing and repressing/decreasing abilities within a chromatin context. Offering a protein engineering platform to alter signal pathway-specific gene expressions and cell growth, our approach could also be used for the development of tools for epigenetic modifications and for clinical interventions wherein multigenic de-regulations are an

issue. Evaluation of oxidative stress and antioxidative action of green tea catechins in patients treated with tamoxifen: a randomized open-label, crossover study MEDITERRANEAN JOURNAL OF NUTRITION AND METABOLISM English Article

Oxidative stress; D-Roms test; BAP test; Green tea catechins; Tamoxifen; Breast cancer The relation between oxidative stress and tamoxifen is not completely clear, since some studies attribute a possible antioxidant action, while others describe several pro-oxidative effects. The aim of this study was to evaluate oxidative stress in patients treated with tamoxifen and the effect of administration of green tea catechins on this parameter. Tests aimed at evaluating the derivatives of reactive oxygen metabolites (d-Roms test) and the antioxidant reserve (BAP test) were adopted to estimate oxidative stress. Subjects treated with tamoxifen received Categ [Sofar] (green tea extract with 200 mg of catechins, 2 tablets twice a day for 3 weeks), according to a crossover design. High or very high antioxidant stress levels were found in all the 46 patients treated with tamoxifen, while in a control group of 18 patients treated with aromatase inhibitors or who had no longer been treated with tamoxifen for 1 year or more, high or very high oxidative stress levels were found in 66.7% of cases ($p < 0.0001$). The antioxidant reserve was low in 52% of patients treated with tamoxifen versus 40% of the patients in the control group, but the difference was not statistically significant ($p = n. s.$). The levels of oxidative stress and antioxidant reserve did not change significantly in a subgroup where the patients took Categ for 3

weeks followed by 3 weeks washout (group A), while there was a statistical significant reduction in the levels of oxidative stress ($p < 0.05$) and an increase in the antioxidant reserve ($p < 0.01$) in the subgroup where 3 weeks of no treatment were followed by 3 weeks of treatment with Categ (group B). In conclusion, our study confirms a pro-oxidant effect of tamoxifen. The supplementation with green tea catechins gave discordant results. A high number of variables might intervene in the delicate oxidative-reductive equilibrium of human beings and, despite progress achieved in the last few years, there are several aspects concerning the oxidative-reductive equilibrium that still have to be explained. J Busby, C; Hamdan, M; Ariabi, E Busby,
Chris; Hamdan, Malak; Ariabi, Entesar Cancer, Infant
Mortality and Birth Sex-Ratio in Fallujah, Iraq 2005-2009

INTERNATIONAL JOURNAL OF ENVIRONMENTAL RESEARCH AND PUBLIC
HEALTH English Article

Fallujah; Iraq; cancer; leukemia; depleted uranium;
gulf war SURVIVORS There have been anecdotal reports of
increases in birth defects and cancer in Fallujah, Iraq blamed on
the use of novel weapons (possibly including depleted uranium) in
heavy fighting which occurred in that town between US led forces
and local elements in 2004. In Jan/Feb 2010 the authors organised
a team of researchers who visited 711 houses in Fallujah, Iraq and
obtained responses to a questionnaire in Arabic on cancer, birth
defects and infant mortality. The total population in the
resulting sample was 4,843 persons with and overall response rate
was better than 60%. Relative Risks for cancer were age-
standardised and compared to rates in the Middle East Cancer
Registry (MECC, Garbiah Egypt) for 1999 and rates in Jordan 1996-
2001. Between Jan 2005 and the survey end date there were 62 cases
of cancer malignancy reported (RR = 4.22; CI: 2.8, 6.6; $p < 0.00000001$) including 16 cases of childhood cancer 0-14 (RR =
12.6; CI: 4.9, 32; $p < 0.00000001$). Highest risks were found in
all-leukaemia in the age groups 0-34 (20 cases RR = 38.5; CI:
19.2, 77; $p < 0.00000001$), all lymphoma 0-34 (8 cases, RR = 9.24;
CI: 4.12, 20.8; $p < 0.00000001$), female breast cancer 0-44 (12
cases RR = 9.7; CI: 3.6, 25.6; $p < 0.00000001$) and brain tumours
all ages (4 cases, RR = 7.4; CI: 2.4, 23.1; $P < 0.004$). Infant
mortality was based on the mean birth rate over the 4 year period

2006–2009 with 1/6th added for cases reported in January and February 2010. There were 34 deaths in the age group 0–1 in this period giving a rate of 80 deaths per 1,000 births. This may be compared with a rate of 19.8 in Egypt (RR = 4.2 $p < 0.00001$) 17 in Jordan in 2008 and 9.7 in Kuwait in 2008. The mean birth sex-ratio in the recent 5-year cohort was anomalous. Normally the sex ratio in human populations is a constant with 1,050 boys born to 1,000 girls. This is disturbed if there is a genetic damage stress. The ratio of boys to 1,000 girls in the 0–4, 5–9, 10–14 and 15–19 age cohorts in the Fallujah sample were 860, 1,182, 1,108 and 1,010 respectively suggesting genetic damage to the 0–4 group ($p < 0.01$). Whilst the results seem to qualitatively support the existence of serious mutation-related health effects in Fallujah, owing to the structural problems associated with surveys of this kind, care should be exercised in interpreting the findings quantitatively. Palestinian Patients with Cancer at King Hussein Cancer
Center FRONTIERS IN ONCOLOGY English Article

Cancer care facilities; Gaza
Strip; Oncology service; Palestinians; West Bank BREAST-CANCER;
HEALTH-CARE; CHALLENGES; BURDEN BackgroundThe Palestinian
Ministry of Health (MoH) routinely refers Palestinian patients
with cancer to King Hussein Cancer Center (KHCC), the largest
cancer center in the Middle East. AimsWe aimed to describe the
characteristics of Palestinian patients with cancer. MethodsWe
performed a retrospective chart review of all Palestinian patients
with cancer who were treated at KHCC during 2018 and 2019, of
which demographic and clinical characteristics were presented.
ResultsWe initially started with 521 cases, out of which 41 (7.9%)
cases were excluded due to misdiagnosis as malignant on pathology
review. We included 480 patients with a confirmed diagnosed of
cancer. Most patients were adults (88.8%) with a mean age of 50.0

+/- 15.0 years ranging from 19 to 87 years. The most common cancer sites in adult men, who comprised 46.9% of the cohort were the hematolymphoid system (23.5%), followed by the digestive system (17.5%), and lung and pleura (11.5%). In women (53.1%), the most common cancer sites were the breast (46.0%), followed by the digestive system (15.0%), and the hematolymphoid system (10.2%). Children and adolescents accounted for 11.3% of the total cases, among which the hematolymphoid system was the most common cancer site (50%), followed by the brain (14.8%). About 36.0% of all patients presented with advanced-stage disease (i.e., distant metastasis). Conclusion The most common cancer sites in our cohort are generally similar to data from the Palestinian territories. Many patients presented with advanced-stage disease, which signals the need for awareness campaigns and screening programs. Benign tumors are misdiagnosed in many patients as cancer. The limited resources and facilities including human resources remain important challenges to the proper and timely diagnosis and management of cancer among Palestinians living in the Palestinian Territories.

Population distribution and ancestry of the cancer
protective MDM2 SNP285 (rs117039649) ONCOTARGET

English	Article	MDM2;
SNP285; SNP309; polymorphism; promoter SINGLE NUCLEOTIDE POLYMORPHISM; ACCELERATES TUMOR-FORMATION; BREAST-CANCER; PROMOTER POLYMORPHISM; EMBRYONIC LETHALITY; MDM2-DEFICIENT MICE; OVARIAN-CANCER; SNP309; RISK; SUSCEPTIBILITY	The MDM2 promoter SNP285C is located on the SNP309G allele. While SNP309G enhances Sp1 transcription factor binding and MDM2 transcription, SNP285C antagonizes Sp1 binding and reduces the risk of breast-, ovary-and endometrial cancer. Assessing SNP285 and 309 genotypes across 25 different ethnic populations (>10.000 individuals), the incidence of SNP285C was 6-8% across European populations except for Finns (1.2%) and Saami (0.3%). The incidence decreased towards the Middle-East and Eastern Russia, and SNP285C was absent among Han Chinese, Mongolians and African Americans. Interhaplotype variation analyses estimated SNP285C to have originated about 14,700 years ago (95% CI: 8,300 - 33,300). Both this estimate and the geographical distribution suggest SNP285C to have arisen after the separation between Caucasians and modern day East Asians (17,000 - 40,000 years ago). We observed a strong inverse correlation ($r = -0.805$; $p < 0.001$) between the percentage of SNP309G alleles harboring SNP285C and the MAF for SNP309G itself across different populations suggesting selection and environmental adaptation with respect to MDM2 expression in recent human evolution. In conclusion, we found SNP285C to be a pan-Caucasian variant. Ethnic variation regarding distribution of SNP285C needs to be taken into account when assessing the impact of MDM2 SNPs on cancer risk.

Modan, B Population attributes affecting the
prevalence of BRCA mutation carriers in epithelial ovarian cancer
cases in Israel GYNECOLOGIC ONCOLOGY English
Article ovarian cancer; BRCA
carriers; Israeli population BREAST-CANCER; JEWISH WOMEN; 185DEL
MUTATION; ASHKENAZI JEWS; HIGH-FREQUENCY; FAMILIES; RISK

Objective. The objective was to evaluate the prevalence of
BRCA1/2 mutations in selected categories of ovarian cancer
patients in Israel. Methods. Blood samples and specimens of
ovarian tumors were obtained in the course of a national case
control study of women with ovarian cancer in Israel. Eight
hundred ninety-six patients with epithelial ovarian cancer, 40
cases with nonepithelial ovarian cancer, and 68 with primary
peritoneal cancer were tested for the BRCA mutations. Analysis of
the three common BRCA mutations in Israel (185delAG, 5382insC in
BRCA1, and 6174delT in BRCA2) was done using a multiplex
polymerase chain reaction assay. A multivariate logistic
regression model was used to assess the association of mutation
carrier status and other factors (age, origin, family history, and
clinical variables). Results. Of the 779 invasive epithelial
ovarian cancer cases, 29.4% were mutation carriers. The prevalence
of the mutations was higher among women below age 60 and in more
advanced cases. The prevalence was low in mucinous tumors. There
was almost a twofold excess of mutations among women with positive
family history (45.7%), but still 26.5% of the family history
negative cases were carriers. As expected, we found a higher rate
of mutation carriers among the Ashkenazi group (34.2%) and 55%

among Ashkenazi women with positive family history. No subjects born in North Africa were mutation positive. Conclusion. BRCA mutations are strongly associated with ovarian cancer and they are present in variable rates in distinct age, ethnic, and histopathologic categories. (C) 2003 Elsevier Science (USA). J Asik, E; Akpınar, Y; Güray, T; İscan, M; Demircigil, GÇ; Volkan, M Asik, Elif; Akpınar, Yeliz; Guray, Tulin; İscan, Mesude; Demircigil, Gonca Cakmak; Volkan, Murvet Cellular uptake, genotoxicity and cytotoxicity of cobalt ferrite magnetic nanoparticles in human breast cells TOXICOLOGY RESEARCH English Article

IRON-OXIDE NANOPARTICLES; BIOMEDICAL APPLICATIONS; GOLD NANOPARTICLES; HIGHLY EFFICIENT; CANCER-CELLS; TOXICITY; SYSTEMS; DESIGN; AGENT; FATE Magnetic nanoparticles (MNPs) have been increasingly used for many years as MRI agents and for gene delivery and hyperthermia therapy, although there have been conflicting results on their safety. In this study, cobalt ferrite magnetic nanoparticles (CoFe-MNPs) were prepared by the co-precipitation method and their surfaces were modified with silica by the sol-gel method. The particle and hydrodynamic sizes, morphology and crystal structure of the bare and silica-coated CoFe-MNPs were evaluated by transmission electron microscopy (TEM), dynamic light scattering (DLS), X-ray diffraction spectroscopy (XRD) and Fourier transform infrared spectroscopy (FTIR). The size of the bare CoFe-MNPs was in the range 8-20 nm and they were homogeneously coated with 3-4 nm silica shells. The bare and silica-coated CoFe-MNPs were agglomerated at physiological pH. However, the sizes of the agglomerates were below 200 nm both in water and complete medium.

The cytotoxic and genotoxic potentials of the bare and silica-coated CoFe-MNPs were evaluated in a metastatic breast cancer cell line, MDA-MB-231, as well as a noncancerous mammary epithelial cell line, MCF-10A, by using XTT cytotoxicity, single-cell gel electrophoresis (comet), and cytokinesis-blocked (CB) micronucleus (CBMN) assays. Characterization studies with TEM, inductively coupled plasma optical emission spectroscopy (ICP-OES) and Prussian blue staining indicated that the CoFe-MNPs were internalized into the cells by energy-dependent endocytosis. The highest amount of uptake was observed in the cancer cells and the uptake of the silica-coated CoFe-MNPs was higher than that of the bare ones in both cell lines. The bare CoFe-MNPs showed higher levels of both cytotoxicity and genotoxicity than the silica-coated CoFe-MNPs. Moreover, the cancer cells seemed to be more susceptible to the CoFe-MNPs' toxicity compared to the noncancerous cells. There was a concentration and time-dependent increase in DNA damage and the micronucleus (MN) frequency, which was statistically significant starting with the lowest concentration of bare CoFe-MNPs ($p < 0.05$), while no significance was observed below the concentration of 250 $\mu\text{g mL}^{-1}$ for the silica-coated MNPs. Also, the extent of both DNA damage and MN frequency was much higher in the cancer cells compared to the noncancerous cells. According to our results, the silica coating ameliorated both the cytotoxicity and genotoxicity as well the internalization of the CoFe-MNPs. Circulating cell-free DNA (ccfDNA) is a liquid biopsy biomaterial attracting significant attention for the implementation of precision medicine diagnostics. Deeper knowledge related to its structure and biology would enable the development of such applications. In this study, we employed Raman spectroscopy to unravel the biomolecular profile of human ccfDNA in health and disease. We established reference Raman spectra of ccfDNA samples from healthy males and females with different conditions, including cancer and diabetes, extracting information about their chemical composition. Comparative observations showed a distinct spectral pattern in ccfDNA from breast cancer patients taking neoadjuvant therapy. Raman analysis of ccfDNA from healthy, prediabetic, and diabetic males uncovered some differences in their biomolecular fingerprints. We also studied ccfDNA released from human benign and cancer cell lines and compared it to their respective gDNA, confirming it mirrors its cellular origin. Overall, we explored for the first time Raman spectroscopy in the study of ccfDNA and provided spectra of samples from different sources. Our findings introduce Raman spectroscopy as a new approach to implementing liquid biopsy diagnostics worthy of further elaboration. Effects of the

Ser326Cys Polymorphism in the DNA Repair OGG1 Gene on Cancer, Cardiovascular, and All-Cause Mortality in the PREDIMED Study: Modulation by Diet JOURNAL OF THE ACADEMY OF NUTRITION AND DIETETICS English Article

Cancer; Cardiovascular; Mortality; Nutrigenetics; Vegetables BASE-EXCISION-REPAIR; SQUAMOUS-CELL CARCINOMA; OXIDATIVELY DAMAGED DNA; MITOCHONDRIAL-DNA; MEDITERRANEAN DIET; RISK-FACTORS; LUNG-CANCER; PATHWAY GENES; KNOCKOUT MICE; BREAST-CANCER Background Oxidatively induced DNA damage, an important factor in cancer etiology, is repaired by oxyguanine glycosylase 1 (OGG1). The lower repair capacity genotype (homozygote Cys326Cys) in the OGG1-rs1052133 (Ser326Cys) polymorphism has been associated with cancer risk. However, no information is available in relation to cancer mortality, other causes of death, and modulation by diet. Objective Our aim was to evaluate the association of the OGG1-rs1052133 with total, cancer, and cardiovascular disease (CVD) mortality and to analyze its modulation by the Mediterranean diet, focusing especially on total vegetable intake as one of the main characteristics of this diet. Design Secondary analysis in the PREDIMED (Prevencion con Dieta Mediterranea) trial is a randomized, controlled trial conducted in Spain from 2003 to 2010. Participants/setting Study participants (n = 7,170) were at high risk for CVD and were aged 55 to 80 years. Intervention Participants were randomly allocated to two groups with a Mediterranean diet intervention or a control diet. Vegetable intake was measured at baseline. Main outcome measures Main outcomes were all-cause, cancer, and CVD mortality after a median follow-up of 4.8 years. Statistical analyses Multivariable-adjusted Cox regression models were fitted. Results Three hundred

eighteen deaths were detected (cancer, $n = 127$; CVD, $n = 81$; and other, $n = 110$). Cys326Cys individuals (prevalence 4.2%) presented higher total mortality rates than Ser326-carriers ($P = 0.009$). The multivariable-adjusted hazard ratio for Cys326Cys vs Ser326-carriers was 1.69 (95% CI 1.09 to 2.62; $P = 0.018$). This association was greater for CVD mortality ($P = 0.001$). No relationship was detected for cancer mortality in the whole population (hazard ratio 1.07; 95% CI 0.47 to 2.45; $P = 0.867$), but a significant age interaction ($P = 0.048$) was observed, as Cys326Cys was associated with cancer mortality in participants <66.5 years ($P = 0.029$). Recessive effects limited our ability to investigate Cys326Cys x diet interactions for cancer mortality. No statistically significant interactions for total or CVD mortality were found for the Mediterranean diet intervention. However, significant protective interactions for CVD mortality were found for vegetable intake (hazard ratio interaction per standard deviation 0.42; 95% CI 0.18 to 0.98; $P = 0.046$).

Conclusions In this population, the Cys326Cys-OGG1 genotype was associated with all-cause mortality, mainly CVD instead of cancer mortality. Additional studies are needed to provide further evidence on its dietary modulation.

Sen, Ananda; Ren, Jianwei; Ruffin, Mack T.; Turgeon, Danielle K.; Brenner, Dean E.; Sidahmed, Elkhansa; Rapai, Mary E.; Cornellier, Maria L.; Djuric, Zora Relationships between Serum and Colon Concentrations of Carotenoids and Fatty Acids in Randomized Dietary Intervention Trial CANCER PREVENTION RESEARCH English Article

POLYP PREVENTION TRIAL; COLORECTAL-CANCER RISK; MEDITERRANEAN DIET; BETA-CAROTENE; PLASMA CAROTENOIDS; ALPHA-TOCOPHEROL; EPITHELIAL-CELLS; HIGH-FRUIT; HIGH-FIBER; VITAMIN-A Little is known about the effect of preventive diets on colonic nutrient concentrations. This study randomized 120 persons at increased risk of colon cancer to a Mediterranean versus a Healthy Eating diet for six months. The former targeted increases in whole grains, fruits, vegetables, monounsaturated, and n3 fats. The Healthy Eating diet was based on Healthy People 2010 recommendations. At baseline, dietary fat and carotenoid intakes were poorly associated (Spearman $\rho < 0.4$) with serum and colon concentrations. Strong associations were observed between serum and colon measurements of beta-cryptoxanthin ($\rho = 0.58$; $P < 0.001$), alpha-carotene ($\rho = 0.48$; $P < 0.001$), and beta-carotene ($\rho = 0.45$; $P < 0.001$). After six months, the Healthy Eating intervention increased serum lutein, beta-, and alpha-carotene significantly ($P < 0.05$). In the Mediterranean arm, the significant increases were in serum lutein, beta-cryptoxanthin, beta-carotene, monounsaturated, and n3 fats. A significant group-by-time interaction ($P = 0.03$) was obtained for monounsaturated fats. Colonic increases in carotenoids and n3 fats were significant only in Healthy Eating arm, whereas the group-by-time interaction was significant for beta-carotene ($P = 0.02$) and alpha-carotene ($P = 0.03$). Changes in colon concentrations were

not significantly associated with reported dietary changes. Changes in colon and serum concentrations were strongly associated for beta-cryptoxanthin ($\rho = 0.56$; $P < 0.001$) and alpha-carotene ($\rho = 0.40$; $P < 0.001$). The associations between colonic and serum concentrations suggest the potential use of using serum concentration as a target in dietary interventions aimed at reducing colon cancer risk. Gerardo; Netti, Paolo A.; Maurea, Nicola Nano-Encapsulation of Coenzyme Q10 in Secondary and Tertiary Nano-Emulsions for Enhanced Cardioprotection and Hepatoprotection in Human Cardiomyocytes and Hepatocytes During Exposure to Anthracyclines and Trastuzumab INTERNATIONAL JOURNAL OF NANOMEDICINE English Article

cardio-oncology; nano-medicine; Coenzyme Q(10); doxorubicin; trastuzumab; inflammation FACTOR-KAPPA-B; BREAST-CANCER; HEART-FAILURE; CARDIOVASCULAR COMPLICATIONS; ADJUVANT TRASTUZUMAB; FATTY-ACIDS; CARDIOTOXICITY; THERAPY; DOXORUBICIN; DIAGNOSIS Introduction: CoenzymeQ(10) (CoQ(10)) is a well-known antioxidant and anti-inflammatory agent with cardioprotective properties. However, clinical trials based on its oral administration have failed to provide significant effect on cardiac functionality. The main limitation of CoQ(10) is based on its very low oral bioavailability and instability that limit dramatically its effects as a cardioprotective agent. Herein, we loaded CoQ(10) in high bioavailable nano-emulsions (NEs) coated with chitosan or chitosan and hyaluronic acid in order to improve its performance. Methods: We tested cardioprotective and hepatoprotective effects of CoQ(10)-loaded nanocarriers against Doxorubicin and Trastuzumab toxicities in cardiomyocytes and liver cells through analysis of cell viability, lipid peroxidation, expression of leukotrienes, p65/NF-kB and pro-inflammatory cytokines involved in anticancer-induced cardio and hepatotoxicity. Results: Nano-carriers showed high stability and loading ability and increased cell viability both in hepatocytes and cardiomyocytes during anticancer treatments. We observed that these effects are mediated by the inhibition of lipid peroxidation and reduction of the inflammation. CoQ(10)-loaded nano-emulsions showed also strong anti-inflammatory effects reducing leukotriene B4 and p65/NF-kappa B expression and Interleukin 1 beta and 6 production during anticancer treatments. Discussion: Anthracyclines and Human epidermal growth factor receptor (HER2) inhibitors have shown significant anticancer effects in clinical practice but their use is characterized by cardiotoxicity and hepatotoxicity. Nano-carriers loaded with CoQ(10) showed cardio and hepatoprotective properties mediated by reduction of oxidative damages and pro-inflammatory mediators. These results set the stage for preclinical studies of cardio and hepatoprotection in HER2+ breast cancer-bearing mice treated with Doxorubicin and Trastuzumab. patterns and acculturation in cancer risk and mortality among
postmenopausal Hispanic women: results from the Women's Health
Initiative (WHI) JOURNAL OF PUBLIC HEALTH-HEIDELBERG

English Article Dietary
pattern; Acculturation; Cancer; Hispanic women; Mexican diet

BASE-LINE CHARACTERISTICS; INFLAMMATORY INDEX; COLORECTAL-
CANCER; BREAST-CANCER; MEDITERRANEAN DIET; QUALITY INDEXES;
UNITED-STATES; EATING INDEX; ASSOCIATION; METAANALYSIS Aim To
investigate the association between dietary patterns and total and
obesity-related cancer risk as well as to examine if acculturation
modifies this relationship. Subjects and methods Dietary intake of
postmenopausal Hispanic women (N = 5,482) enrolled in the Women's
Health Initiative was estimated from a Food Frequency
Questionnaire and used to calculate dietary pattern scores:
Healthy Eating Index-2015 (HEI-2015), Mexican Diet (MexD) score,
alternate Mediterranean Diet Score (aMED), and the energy adjusted
Dietary Inflammatory Index (E-DII (TM)). Associations were
evaluated using Cox proportional hazard regression models. Results
Six hundred thirty-one cancers and 396 obesity-related cancers
were diagnosed over a mean follow-up of 12 years. Across dietary
scores, there were no significant associations with cancer risk or
mortality. Trend analysis suggested a potentially lower risk for
total cancer mortality related to the highest MexD score (HR 0.68,
95% CI 0.45-1.04, P-trend = 0.03) and lower risk for obesity-
related cancer mortality related to the highest score category for
MexD (HR 0.65, 95% CI 0.37-1.16, P-trend = 0.02) and aMED (HR 0.87,
95% CI 0.45-1.67, P-trend = 0.04). Further analysis suggested less
acculturated women with higher MexD scores had a 56% lower risk
for any cancer (HR 0.44, 95% CI 0.22-0.88, P-trend = 0.03) and 83%
lower risk for cancer mortality (HR 0.17, 95% CI 0.04-0.76, P-trend
= 0.01) compared to more acculturated Hispanic women. Conclusions
Dietary patterns were not associated with cancer risk and
mortality in postmenopausal Hispanic women. Less acculturated,
Spanish-preferred speakers who report consuming a more traditional
Mexican diet may experience a lower risk of cancer and cancer
mortality. [Lopez-Pentecost, Melissa] Univ Arizona, Coll Med,

Everolimus (RAD001) sensitizes prostate cancer cells to
docetaxel by down-regulation of HIF-1 α and sphingosine kinase 1
ONCOTARGET English Article

MAMMALIAN TARGET; BREAST-CANCER; UP-
REGULATION; DOUBLE-BLIND; MTOR; INHIBITION; EXPRESSION; RAPAMYCIN;
PHOSPHORYLATION; CHEMOTHERAPY Resistance to docetaxel is a key
problem in current prostate cancer management. Sphingosine kinase
1 (SK1) and phosphoinositide 3-kinase (PI3K)/Akt/mammalian target
of rapamycin (mTOR) pathways have been implicated in prostate
cancer chemoresistance. Here we investigated whether their
combined targeting may re-sensitize prostate cancer cells to
docetaxel. In hormone-insensitive PC-3 and DU145 prostate cancer
cells the mTOR inhibitor everolimus (RAD001) alone did not lead to
significant cell death, however, it strongly sensitized cells to
low levels (5 nM) of docetaxel. We show that mTOR inhibition has
led to a decrease in hypoxia-inducible factor-1 alpha (HIF-1
alpha) protein levels and SK1 mRNA. HIF-1 alpha accumulation
induced by CoCl2 has led to a partial chemoresistance to
RAD001/docetaxel combination. SK1 overexpression has completely
protected prostate cancer cells from RAD001/docetaxel effects.
Using gene knockdown and CoCl2 treatment we showed that SK1 mRNA
expression is downstream of HIF-1 alpha. In a human xenograft
model in nude mice single RAD001 and docetaxel therapies induced
23% and 15% reduction in prostate tumor volume, respectively,
while their combination led to a 58% reduction. RAD001 alone or in
combination with docetaxel has suppressed intratumoral mTOR and
SK1 signaling, however as evidenced by tumor size, it required
docetaxel for clinical efficacy. Combination therapy was well
tolerated and had similar levels of toxicity to docetaxel alone.
Overall, our data demonstrate a new mechanism of docetaxel
sensitization in prostate cancer. This provides a mechanistic
basis for further clinical application of RAD001/docetaxel
combination in prostate cancer therapy. [Alshaker, Heba; Wang, Qi;

Cancer incidence in the East Azerbaijan province of Iran in 2015-2016: results of a population-based cancer

registry BMC PUBLIC HEALTH English Article

Cancer; Registry; Population-based; Iran; Incidence HUMAN PAPILLOMA-VIRUS; EMERGING RISK-FACTOR; ESOPHAGEAL CANCER; GASTRIC-CANCER; COLORECTAL-CANCER; OPIUM USE; MORTALITY; EPIDEMIOLOGY; METAANALYSIS; GOLESTAN

Background Few countries in the Middle East have a population-based cancer registry, despite a clear need for accurate cancer statistics in this region. We therefore established a registry in the East Azerbaijan province, the sixth largest province in northwestern Iran. Methods We actively collected data from 20 counties, 62 cities, and 44 districts for the period between 20(th) March 2015 and 19(th) March 2016 (one Iranian solar year). The CanReg5 software was then used to estimate age-standardized incidence rates (ASRs) per 100,000 for all cancers and different cancer types. Results Data for 11,536 patients were identified, but we only analyzed data for 6655 cases after removing duplicates and non-residents. The ASR for all cancers, except non-melanoma skin cancer, was 167.1 per 100,000 males and 125.7 per 100,000 females. The most common cancers in men were stomach (ASR 29.7), colorectal (ASR 18.2), bladder (ASR 17.6), prostate (ASR 17.3), and lung (ASR 15.4) cancers; in women, they were breast (ASR 31.1), colorectal (ASR 13.7), stomach (13.3), thyroid (ASR 7.8), and esophageal (ASR 7.1) cancers. Both the death certificate rate (19.5%) and the microscopic verification rate (65%) indicated that the data for the cancer registry were of reasonable quality. Conclusion The results of the East Azerbaijan Population-based Cancer Registry show a high incidence of cancer in this province, especially gastrointestinal cancers. Synthesis, antiproliferative, antibacterial activity of acridone derivatives: Experimental and theoretical calculations JOURNAL OF MOLECULAR STRUCTURE

English Article Acridine derivatives; Ultraviolet-visible; Quantum chemical calculations; Docking; Antimicrobial activity OVARIAN-CANCER; MOLECULAR DOCKING; BIOLOGICAL-ACTIVITIES; GROWTH A new ethyl 5-(2-(9-oxoacridin-10(9H)-yl)acetamido) thiophene-2-carboxylate (EATPC) and ethyl 2-(2-(9oxoacridin-10(9H)-yl)acetamido)thiazole-5-carboxylate (EATZC) acridone derivatives were successfully synthesized and described using NMR, UV-Vis and FTIR spectroscopy approaches. The theoretical calculations were computed using Gaussian 09 W software employing DFT/TD-DFT/B3LYP methods with a basis set of 6-311+G (d,p). The calculated and observed spectroscopy results are compared and discussed, demonstrating the reliability of the developed structure of compounds. The natural bond orbital, molecular electrostatic potential, physicochemical descriptors and HOMO-LUMO energies were all calculated and thoroughly discussed in the present study. EATPC and EATZC were tested for antiproliferative capabilities against human breast cancer (MCF-7) cell lines by employing the MTT assay. Furthermore,

molecular docking analyses were performed to determine the compound's most active binding sites to the target protein. The molecules EATPC and EATZC are docked with the 4E28 protein, yielding free binding energy energies of -7.8 and -7.9 kcal/mol. This study is unique in that it is the first in-depth report on the comprehensive biological and theoretical evaluation of these title compounds. D-Limonene in citrus fruit with anticarcinogenic action

ERNAHRUNGS-UMSCHAU

German Article

D-Limonene; citrus fruit;

anticarcinogenic action

PERILLYL ALCOHOL; INHIBITION;

MONOTERPENE; METABOLITES; CANCER D-limonene, a monoterpene, is a main component of the volatile oils of citrus-fruit peels. At temperatures not exceeding 50 degreesC limonene, if protected against light, is not susceptible to oxidation. High levels of limonene are contained in fresh Mediterranean-style lemonade (prepared from whole lemons) (up to 1 g/l) and in commercial citrus juices (up to 85 mg/l). Limonene is completely absorbed and extensively metabolized. About 24 h after intake, 70 % of the limonene ingested are renally excreted. As soon as 4 h after intake, only traces of limonene and its major metabolites perillilic acid, dihydroperillilic acid and limonene-1,2-diol, as well as traces of the methyl esters of these acids and of limonene-8,9-diol and iso-perillilic acid are still present in the plasma. Maximum concentrations of limonene and its metabolites have been found in fatty, mammary and liver tissue. In the tumor tissue of patients with breast cancer, limonene levels were six times as high as those in the plasma. Major urinary metabolites are glycine and glucuronyl conjugates of the perillilic acid isomers, dihydroperillilic acid, limonene-6-ol (carveol), perillylalcohol and traces of limonene-8,9-diol (uroterpenol). In vivo, limonene has preventive and therapeutic effects on chemically induced tumors of different rat and mouse tissues. At the same time isoprenylation of cell growth associated 21-26 kDa proteins and of the corresponding protein prenyltransferases are inhibited. This also applies to the 3-hydroxy-3-methyl glutaryl CoA reductase resulting in a decrease of farnesyl and geranylgeranyl pyrophosphate pools.

Besides, the carcinogen-metabolizing liver enzymes glutathione-S transferase and uridin diphosphoglucuronosyl transferase are activated. In- vitro experiments in human cancer cells have shown that the limonene metabolites perillyl alcohol, perillic acid and limonene-1,2-diol, and not limonene itself, are most effective in inhibiting 21-26 kDa protein isoprenylation. In preclinical studies in patients with advanced cancer the maximum tolerable oral dose applied for several month was 13.8 g limonene per day. In some cases tumor growth was inhibited.

VACCINE; PHASE-I; RECOMBINANT VECTOR; SPIKE PROTEIN; MERS-COV;
THERAPEUTIC VACCINATION The Brighton Collaboration Benefit-
Risk Assessment of Vaccines by Technology (BRAVATO) was formed to
evaluate the safety and other key features of new platform
technology vaccines. This manuscript provides an overview of
Modified Vaccinia virus Ankara (MVA)-vectored vaccines and reviews
molecular and biological key features of this platform. In
particular, this review aims to provide fundamental information
about the promising candidate vaccine MVA-MERS-S which has been
evaluated successfully in different preclinical animal models and
has undergone clinical testing including a phase Ib study
involving more than 170 participants. Infectious diseases continue
to be a major cause of human death worldwide. In this context,
emerging zoonotic infectious diseases pose a particular challenge
for public health systems. In the last two decades, three
different respiratory coronaviruses, including the Middle East
respiratory syndrome Coronavirus (MERS-CoV) have emerged. For many
years, safe and efficacious vaccines have been a major tool to
combat infectious diseases. Here, we report on a promising
candidate vaccine (MVA-MERS-S) against MERS-CoV based on MVA. Upon
application, MVA-MERS-S has been well tolerated and immunogenic,
inducing both, cellular and humoral immune responses in different
animal models and humans. We demonstrate that the MVA vector
platform, with the example of MVA-MERS-S, is a viable and
effective tool for producing safe, immunogenic, and efficient
vaccines against emerging infectious diseases. [Link, Ellen

Inulin coated plasmonic gold nanoparticles as a
tumor-selective tool for cancer therapy JOURNAL OF MATERIALS
CHEMISTRY B English Article
DELIVERY-SYSTEMS; PHASE-TRANSFER; DOXORUBICIN;
SPIONS; CELLS; DRUG Polymer coated gold nanospheres are
proposed as a tumor selective carrier for the anticancer drug
doxorubicin. Thiolated polyethyleneglycol (PEG-SH) and an inulin-
amino derivative based copolymer (INU-EDA) were used as
stabilizing and coating materials for 40 nm gold nanospheres. The
resulting polymer coated gold nanospheres (Au@PEG-INU) showed
excellent physicochemical stability and potential stealth like
behavior. The system was loaded with doxorubicin (Au@PEG-INU/Doxo)
and its cytotoxicity profile was evaluated on human cervical
cancer cells (HeLa) and lung cancer cells (A549), as compared to
Au@PEG-INU and doxorubicin alone. Cytotoxicity assays showed that
the system is able to drastically reduce cell viability upon
incubation for 3 days. This result was supported by the ability of
Au@PEG-INU/Doxo to be internalized by cancer cells and to release
doxorubicin, as assessed by fluorescence microscopy. Finally, a
cancer/non cancer cell co-culture model was used to display the
advantageous therapeutic effects of the proposed system with
respect to doxorubicin alone, thereby demonstrating the ability of
Au@PEG-INU/Doxo to preferentially accumulate in tumor cells due to
their enhanced metabolism, and to selectively kill target cells.

AUSTRALIAN JOURNAL OF DAIRY TECHNOLOGY English

Article; Proceedings Paper 7th Dairy Science World Series Conference (DSWS) JUL 24-25, 2006 Sydney, AUSTRALIA

CORONARY-HEART-DISEASE; DAIRY-PRODUCTS;

MEDITERRANEAN DIET; BLOOD-PRESSURE; GLUCOSE-TOLERANCE; FERMENTED MILK; BREAST-CANCER; FATTY-ACIDS; RISK; CONSUMPTION There is increasing evidence to support the contribution that cheese can make to an optimal healthy diet. Recent epidemiological studies have shown that communities living on a 'Mediterranean diet' have a significantly lower risk of death from cardiovascular disease and cancers. A significant component of that diet is of dairy origin, mainly as cheeses and/or yogurts. Components in dairy products that could be delivering health benefits include components of cheese fats: omega 3 fatty acids and conjugated linoleic acid (CLA). Significantly increased amounts of omega 3 long chain fatty acids (omega 3 LCFAs) in Greek eggs and dairy products over similar American products have been observed. We

review here some of the evidence regarding the potential contribution of w3 fatty acids and CLA in dairy fat to disease prevention. The current work used pre-intervention data collected from 9576 children-parents pairs, to develop a novel family obesity variable and to examine its associations with family sociodemographic and lifestyle characteristics. Family obesity, defined as the presence of obesity in at least two family members, had a prevalence of 6.6%. Countries under austerity measures (Greece and Spain) displayed higher prevalence (7.6%), compared to low-income (Bulgaria and Hungary: 7%) and high-income countries (Belgium and Finland: 4.5%). Family obesity odds were significantly lower when mothers (OR: 0.42 [95% CI: 0.32, 0.55]) or fathers (0.72 [95% CI: 0.57, 0.92]) had higher education, mothers were fully (0.67 [95% CI: 0.56, 0.81]) or partially employed (0.60 [95% CI: 0.45, 0.81]), families consumed breakfast more often (0.94 [95% CI: 0.91 0.96]), more portions of vegetables (0.90 [95% CI: 0.86, 0.95]), fruits (0.96 [95% CI: 0.92, 0.99]) and wholegrain cereals (0.72 [95% CI: 0.62, 0.83]), and for more physically active families (0.96 [95% CI: 0.93, 0.98]). Family obesity odds increased when mothers were older (1.50 [95% CI: 1.18, 1.91]), with the consumption of savoury snacks (1.11 [95% CI: 1.05, 1.17]), and increased screen time (1.05 [95% CI: 1.01,

1.09])). Clinicians should familiarise themselves with the risk factors for family obesity and choose interventions that target the whole family. Future research should explore the causal basis of the reported associations to facilitate devising tailored family-based interventions for obesity prevention.  FEATURES; LOADED LIPOSOMES; CELLULAR UPTAKE; GENE DELIVERY;
 GEMCITABINE; CANCER; POLYASPARTYLHYDRAZIDE; BIODISTRIBUTION The
 biopharmaceutical properties of supramolecular vesicular
 aggregates (SVAs) were characterized with regard to their
 physicochemical features and compared with cationic liposomes
 (CLs). Neutral and cationic SVAs were synthesized using two
 different copolymers of poly(aspartyl hydrazide) by thin-layer
 evaporation and extrusion techniques. Both copolymers were self-
 assembled in pre-formulated liposomes and formed neutral and
 cationic SVAs. Gemcitabine hydrochloride (GEM) was used as an
 anticancer drug and loaded by a pH gradient remote loading
 procedure, which significantly increased drug loading inside the
 SVAs. The resulting average size of the SVAs was 100nm. The
 anticancer activity of GEM-loaded neutral and cationic SVAs was
 tested in human alveolar basal epithelial (A549) and colorectal
 cancer (CaCo-2) cells. GEM-loaded cationic SVAs increased the
 anticancer activity in A549 and CaCo-2 cells relative to free
 drug, neutral SVAs, and CLs. In vivo biodistribution in Wistar rats
 showed that cationic SVAs accumulate at higher concentrations in
 lung tissue than neutral SVAs and CLs. Cationic SVAs may therefore
 serve as an innovative future therapy for pulmonary carcinoma.

An interethnic
variability and a functional prediction of DNA repair gene
polymorphisms: the example of XRCC3 (p.Thr241>Met) and XPD
(p.Lys751>Gln) in a healthy Tunisian population MOLECULAR
BIOLOGY REPORTS English Article

DNA repair; Polymorphism; Genotyping; Ethnic
variability; Functional prediction; Tunisian population BREAST-
CANCER RISK; LUNG-CANCER; HOMOLOGOUS RECOMBINATION; COLORECTAL-
CANCER; ADDUCTS; RAD51; CELLS; METAANALYSIS; ASSOCIATION;
INSTABILITY Genetic polymorphisms in DNA repair genes might
influence the repair activities of the enzymes predisposing
individuals to cancer risk. Owing to the presence of these genetic
variants, interethnic differences in DNA repair capacity have been
observed in various populations. The present study was undertaken
to determine the allele and genotype frequencies of two common
non-synonymous SNPs, XRCC3 p.Thr241 > Met (C > T, rs861539) and
XPD p.Lys751 > Gln (T > G, rs13181) in a healthy Tunisian
population and to compare them with HapMap
(<http://www.hapmap.org/>) populations. Also, we predicted their
eventual functional effect based on bioinformatics tools. The
genotypes of 154 healthy and unrelated individuals were determined
by PCR-RFLP procedure. Our findings showed a close relatedness
with Caucasians from European ancestry which might be explained by
the strategic geographic location of Tunisia in the Mediterranean,
thus allowing exchanges with Europeans countries. The in silico
predictions showed that p.Thr241 > Met substitution in XRCC3
protein was predicted as possibly damaging, indicating that it is
likely to have functional consequences as well. To the best of our
knowledge, this is the first study in this regard in Tunisia. So,
these data could provide baseline database and help us to explore
the relationship of XRCC3 and XPD polymorphisms with both cancer

risk and DNA repair variability in our population. M. M. A. Stage II cancer diagnosis using printed

antenna implemented on hemispherical model for human breast
JOURNAL OF INSTRUMENTATION English Article

Antennas; Microwave Antennas
TUMOR DETECTION; TISSUES; ARRAY; BODY In this paper
electromagnetic properties of a female human breast are used for
cancer diagnosis. Deviation of the malignant cells' properties
from those of healthy cells' directly affect the performance of an
antenna placed on the breast. Return loss, gain and directivity of
an antenna designed on an FR4 substrate were used as parameters
for studying the effects of normal and cancerous tissue. A
hemispherical shaped breast model is presented covering the
breast, skin, fat and part of the connected lymph nodes. Tumors in
breast and lymph nodes with different sizes and numbers were used
to illustrate the second stage of cancer diagnosis. The antenna
was designed and fabricated, and return loss measurements were
taken using a network analyzer. Separate measurements were taken
in free space and when placed on a healthy human breast. The
return loss was simulated using CST Microwave Studio for antenna
implemented on normal breast models and it is in good agreement
with those of the measured results. The presented work has shown
to be a preliminary model way for breast cancer diagnosis thereby
reducing the need for invasive surgical operations. [Ali, N.;

diet; dietary patterns; gene expression; tissue; colon; nutrigenomics BLOOD MONONUCLEAR-CELLS; FATTY-ACIDS; MEDITERRANEAN DIET; OXIDATIVE STRESS; CANCER; RISK; ASSOCIATIONS; INFLAMMATION; NUTRITION; ADHERENCE (1) Introduction: The global rise of gastrointestinal diseases, including colorectal cancer and inflammatory bowel diseases, highlights the need to understand their causes. Diet is a common risk factor and a crucial regulator of gene expression, with alterations observed in both conditions. This study aims to elucidate the specific biological mechanisms through which diet influences the risk of bowel diseases. (2) Methods: We analyzed data from 436 participants from the BarcUVa-Seq population-based cross-sectional study utilizing gene expression profiles (RNA-Seq) from frozen colonic mucosal biopsies and dietary information from a semi-quantitative food frequency questionnaire. Dietary variables were evaluated based on two dietary patterns and as individual variables. Differential expression gene (DEG) analysis was performed for each dietary factor using edgeR. Protein-protein interaction (PPI) analysis was conducted with STRINGdb v11 for food groups with more than 10 statistically significant DEGs, followed by Reactome-based enrichment analysis for the resulting networks. (3) Results: Our findings reveal that food intake, specifically the consumption of blue fish, alcohol, and potatoes, significantly influences gene expression in the colon of individuals without tumor pathology, particularly in pathways related to DNA repair, immune system function, and protein glycosylation. (4) Discussion: These results demonstrate how these dietary components may influence human metabolic processes and affect the risk of bowel diseases.  M. Chemical Composition, Antitumor Potential, and
 Impact on Redox Homeostasis of the Essential Oils of Orlaya
 grandiflora from Two Climate LocalitiesMOLECULES

English Article Orlaya
 grandiflora; essential oils; chemical composition; cancer cell
 lines; antitumor potential; redox homeostasis; cell migration

OXIDATIVE STRESS; REACTIVE OXYGEN; GROWING WILD; NITRIC-
 OXIDE; APIACEAE; GROWTH; SYSTEM; CELLS It is well known that
 abiotic components can affect biosynthetic pathways in the
 production of certain volatile compounds. The aim of this study
 was to compare the chemical composition of essential oils obtained
 from Orlaya grandiflora (L.) Hoffm. collected from two localities
 in Serbia (continental climate, OG1) and Montenegro (Mediterranean
 climate, OG2) and to assess their antitumor potential on the human
 colon cancer HCT-116 and breast cancer MDA-MB-231 cell lines. EOs
 obtained by hydrodistillation were analyzed using GC-MS and GC-FID
 methods. The results indicate considerable differences in the

chemical compositions of the two samples. Although in both samples the main class of volatiles observed was sesquiterpenes (47.5% for OG1 and 70.1% for OG2), the OG1 sample was characterized by a high amount of monoterpene hydrocarbons (29.3%), and sesquiterpene germacrene D (29.5%) as the most abundant compound. On the other hand, the OG2 sample contained a high quantity of oxygenated sesquiterpenes (20.6%), and beta-elemene (22.7%) was the major constituent. The possible antitumor mechanisms of these EOs in the HCT-116 and MDA-MB-231 cell lines were examined by means of cell viability, apoptosis, redox potential, and migratory capacity. The antiviability potential appeared to be dose dependent, since the results showed that both EOs decreased the viability of the tested cells. Stronger antitumor effects were shown in MDA-MB-231 cells after short-term treatment, especially at the highest applied concentration, where the percentage of viability was reduced by over 40%. All tested concentrations of EOs exhibited proapoptotic activity and elevated activity of caspase-3 in a dose- and time-dependent manner. The results also showed decreased concentrations of superoxide anion radical in the treated cells, which indicates their significant antioxidative role. Long-term treatments showed mild recovery effects on cell viability in both cell lines, probably caused by the balancing of redox homeostasis. Elevated levels of nitrites indicate high levels of nitric oxide (NO) production and suggest its higher bioavailability due to the antioxidative environment. The tested EOs also induced a drop in migratory capacity, especially after short-time treatments. Taken together, these results suggest considerable antitumor activity of both EOs, which could have potential therapeutic applications.

MEDITERRANEAN DIET; COLORECTAL-CANCER; PROSTATE-CANCER; MESSENGER-RNA; IN-VITRO; EXPRESSION; MMP-2; METASTASIS; CARCINOMA; GROWTH The consumption of extra virgin olive oil (EVOO), a common dietary habit of the Mediterranean people, seems to be related to a lower incidence of certain types of cancer including bladder neoplasm. Metastases are the major cause of bladder cancer-related deaths and targeting cell motility has been proposed as a therapeutic strategy to prevent cancer spread. This study aimed to investigate the potential antimetastatic effect of total phenols extracted from EVOO against the human transitional bladder carcinoma cell line T24. We also aimed at verifying that EVOO extract exerts cytotoxic effect on tumor cells without affecting normal urothelial fibroblasts. Our results show that EVOO extract can significantly inhibit the proliferation and motility of T24 bladder cells in a dose-dependent manner. In the same experimental conditions fibroblast proliferation and motility were not significantly modified. Furthermore the enzymatic activity of MMP-2 was inhibited at nontoxic EVOO extract doses only in T24 cells. The qRT-PCR revealed a decrease of the MMP-2 expression and a simultaneous increase of the tissue inhibitors of metalloproteinases expression. Our results may support the epidemiological evidences that link olive oil consumption to health benefits and may represent a starting point for the development of new anticancer strategies. Heat shock protein 60 levels in tissue and circulating
exosomes in human large bowel cancer before and after ablative
surgery CANCER English Article

heat shock protein 60 (Hsp60); colon
adenocarcinoma; exosomes; plasma cell membrane; natural killer
cells; macrophages; theranostics HEAT-SHOCK PROTEINS; COLORECTAL-
CANCER; HSP60; APOPTOSIS; RELEASE; CELLS; CHAPERONOPATHIES;
IDENTIFICATION; CHAPERONES; EXPRESSION BACKGROUNDHeat shock
protein 60 (Hsp60) is a chaperonin involved in tumorigenesis, but
its participation in tumor development and progression is not well
understood and its value as a tumor biomarker has not been fully
elucidated. In the current study, the authors presented evidence
supporting the theory that Hsp60 has potential as a biomarker as
well as a therapeutic target in patients with large bowel cancer.
METHODSThe authors studied a population of 97 subjects, including
patients and controls. Immunomorphology, Western blot analysis,
and quantitative real-time polymerase chain reaction were
performed on tissue specimens. Exosomes were isolated from blood
and characterized by electron microscopy, biochemical tests, and
Western blot analysis. RESULTSHsp60 was found to be increased in
cancerous tissue, in which it was localized in the tumor cell
plasma membrane, and in the interstitium associated with cells of
the immune system, in which it was associated with exosomes
liberated by tumor cells and, as such, circulated in the blood. An
interesting finding was that these parameters returned to normal
shortly after tumor removal. CONCLUSIONSThe data from the current
study suggested that Hsp60 is a good candidate for theranostics
applied to patients with large bowel carcinoma and encourage
similar research among patients with other tumors in which Hsp60
has been implicated. Cancer 2015;121:3230-3239. (c) 2015 American
Cancer Society. Heat shock protein 60 is a chaperonin involved in
tumorigenesis but its participation in tumor development and
progression is not well understood and its value as a tumor
biomarker has not been fully elucidated. In the current study, the
authors present evidence supporting the theory that heat shock

protein 60 has potential as a biomarker as well as a therapeutic target in patients with colon cancer. Performed under the umbrella agreement between the Euro-Mediterranean Institute of Science and Technology and the Institute of Marine and Environmental Technology signed in March 2012 (IMET contribution number 15-156). Supported by the Euro-Mediterranean Institute of Science and Technology (to Drs. Cappello and Macario) and funds from the University of Palermo (to Drs. Capello, Bucchieri, David, Sciume, and Zummo) and the European Union COST Action BM1202 (to Mrs Caruso Bavisotto). Part of this work was performed using instruments provided by the Euro-Mediterranean Institute of Science and Technology, and funded by the Italian National Operational Programme for Research and

Competitiveness 2007-2013 grant (project code: PONA3_00210;
European Regional Development Fund). 39 139 145 1

AKR1B10 confers resistance to radiotherapy via FFA/TLR4/NF-
κB axis in nasopharyngeal carcinoma INTERNATIONAL JOURNAL OF
BIOLOGICAL SCIENCES English Article

nasopharyngeal carcinoma; AKR1B10;
radiotherapy resistance; FFA/TLR4/NF-kappa B axis NF-KAPPA-B;
BREAST-CANCER; ALPHA; ACTIVATION; PHOSPHORYLATION; CELLS;
RADIORESISTANCE; REDUCTASE; PROTEIN; EXPRESSION Nasopharyngeal
carcinoma (NPC) is one kind of human head and neck cancers with
high incidence in Southern China, Southeast Asia and North Africa.
In spite of great innovations in radiation and chemotherapy
treatments, the 5-year survival rate is not satisfactory. One of
the main reasons is resistance to radiotherapy which leads to
therapy failure and recurrence of NPC. The mechanism underlying
remains to be fully elucidated. Aldo-keto reductase B10 (AKR1B10)
plays a role in the formation and development of carcinomas.
However, its role in resistance to radiotherapy of NPC is not
clear. In this research, the relationships between AKR1B10
expression and the treatment effect of NPC patients, NPC cell
survival, cell apoptosis, and DNA damage repair, as well as the
effect and mechanism of AKR1B10 expression on NPC radioresistance
were explored. A total of 58 paraffin tissues of NPC patients
received radiotherapy were collected including 30 patients with
radiosensitivity and 28 patients with radioresistance. The
relationships between AKR1B10 expression and the treatment effect
as well as clinical characteristics were analyzed by immuno-
histochemical experiments, and the roles of AKR1B10 in cell
survival, apoptosis and DNA damage repair were detected using the
AKR1B10 overexpressed cell models. Furthermore the mechanism of
AKR1B10 in NPC radioresistance was explored. Finally, the
radioresistance effect of AKR1B10 expression was evaluated by the
tumor xenograft model of nude mice and the method of radiotherapy.
The results showed AKR1B10 expression level was correlated with
radiotherapy resistance, and AKR1B10 overexpression promoted
proliferation of NPC cells, reduced apoptosis and decreased
cellular DNA damage after radiotherapy. The probable molecular
mechanism is that AKR1B10 expression activated FFA/TLR4/NF-kappa B
axis in NPC cells. This was validated by using the TLR4 inhibitor
TAK242 to treat NPC cells with AKR1B10 expression, which reduced
the phosphorylation of NF-kappa B. This study suggests that
AKR1B10 can induce radiotherapy resistance and promote cell
survival via FFA/TLR4/NF-kappa B axis in NPC, which may provide a
novel target to fight against radiotherapy resistance of NPC.

J La Vecchia, C; Tavani, A La Vecchia, C;
Tavani, A Fruit and vegetables, and human cancer
EUROPEAN JOURNAL OF CANCER PREVENTION English
Article; Proceedings Paper Joint International Symposium on
Micronutrients and Human Cancer Risks-Prospects for Prevention
MAY 21-24, 1997 AARHUS, DENMARK diet; fruit;
neoplasms; risk factors; vegetables ATTRIBUTABLE RISKS;
COLORECTAL-CANCER; UNITED-STATES; NORTHERN; DIET; EPIDEMIOLOGY;
CONSUMPTION; MORTALITY; DIVERSITY; BREAST A large body of
evidence indicates that high intakes of fruit and vegetables are
associated with a reduced risk of cancer at several sites. The
association is generally most marked for epithelial cancers,
apparently stronger for those of the digestive and respiratory
tracts, and somewhat weaker for hormone-related cancers. The
relationship between frequency of consumption of vegetables and
fruit and cancer risk was analysed using data from a series of
case-control studies conducted in northern Italy since 1983. The
relative risks (RRs) for most common neoplasms ranged from 0.2 to
0.5 for the highest compared with the lowest tertile of vegetable
intake. Protective effects were highest for epithelial neoplasms,
but were also observed for hormone-related neoplasms. Fruit was
related to reduced RRs for cancers of the oral cavity and pharynx,
oesophagus, stomach, larynx, as well as of the urinary tract.
There was a specific and consistent pattern of protection by
tomatoes, a typical Mediterranean food, with RRs between 0.4 and
0.7, most notably for gastrointestinal neoplasms. No significant
association was observed between fruit and vegetable consumption
and non-epithelial lymphoid neoplasms. For digestive tract cancer,
population attributable risks for low intake of fresh vegetables
and fruit ranged from 15 to 40% of all cases in this Mediterranean
population. Combined with tobacco and alcohol, the population
attributable risks exceeded 85% for men and 55% for women for
upper digestive and respiratory tract neoplasms. Thus, from a
public health viewpoint, epidemiological evidence indicates that a
substantial reduction in epithelial cancer risk can be obtained by
increasing fruit and vegetable consumption. (C) 1998 Rapid Science

Chemical Composition and Biological Activity of *Salvia officinalis* L. Essential Oil PLANTS-BASEL English
Article breast cancer cell

lines; cell viability; human dermal fibroblast; lung cell lines;
MTS assay; *Salvia officinalis* L.; SEM ANTICANCER ACTIVITY;
GLANDULAR HAIRS; DIVERSITY; APOPTOSIS; TRICHOMES; PLANTS; YIELDS

In our study, we investigated the chemical composition and cytotoxic activity of essential oils isolated from Dalmatian sage (*Salvia officinalis* L.) collected along the Adriatic coast of Croatia. Scanning electron microscopy (SEM) was used to examine the morphology of the stem and leaf surfaces. Essential oil excretory glands were detected on both the leaves and stem surfaces. The essential oils were isolated by hydrodistillation, and their chemical composition was determined by gas chromatography and mass spectrometry (GC-MS). Sage essential oils were mixtures of terpene compounds, among which the most common were: alpha- and beta-thujone, camphor, and 1,8-cineol. Cytotoxic activity was tested using MTS assay on multiple cell lines: normal and immortalized fibroblasts (HF77FA and HDF-Tert), immortalized lung line (BEAS-2B), and breast adenocarcinoma (MDA-MB-231). The growth of treated cells was determined relative to control conditions without treatment. The immortalized lung line was the least resistant to the activity of the essential oils, whereas immortalized fibroblasts were the most resistant. Statistical analysis has connected the cytotoxic effect and chemical composition of the studied essential oils. To the best of our knowledge, this work is the first testing of the cytotoxic activity of *S. officinalis* EO's on the BEAS-2B, HF77FA, and HDF-Tert cell lines. The presented data on essential oil chemical composition and cytotoxic effect on 4 types of human cells supports pharmacotherapeutic potential this plant is known to have. J Pitts, SBJ; Keyserling, TC; Johnston, LF; Evenson, KR; McGuirt, JT; Gizlice, Z; Whitt, OR; Ammerman, AS
Pitts, Stephanie B. Jilcott; Keyserling, Thomas C.; Johnston, Larry F.; Evenson, Kelly R.; McGuirt, Jared T.; Gizlice, Ziya; Whitt, Olivia R.; Ammerman, Alice S. Examining the Association between Intervention-Related Changes in Diet, Physical Activity, and Weight as Moderated by the Food and Physical Activity Environments among Rural, Southern Adults

JOURNAL OF THE ACADEMY OF NUTRITION AND DIETETICS
English Article Diet;
Physical activity; Food environment; Built environment; Lifestyle intervention CARDIOVASCULAR-DISEASE RISK; LOW-INCOME WOMEN; NORTH-CAROLINA; LIFE-STYLE; NEIGHBORHOOD ENVIRONMENT; RANDOMIZED-TRIAL; FARMERS MARKETS; OBESITY; WALKING; VALIDATION

Background Few studies have been conducted in rural areas assessing the influence of community-level environmental factors on residents' success improving lifestyle behaviors. Objective Our aim was to examine whether 6-month changes in diet, physical activity, and weight. were moderated by the food and physical activity environment in a rural adult population receiving an intervention designed to improve diet and physical activity. Design We examined associations between self-reported and objectively measured changes in diet, physical activity, and weight, and perceived and objectively measured food and physical activity environments. Participants were followed for 6 months. Participants/setting Participants were enrolled in the Heart Healthy Lenoir Project, a lifestyle intervention study conducted in Lenoir County, located in rural southeastern North Carolina. Sample sizes ranged from 132 to 249, depending on the availability of the data. Intervention Participants received four counseling sessions that focused on healthy eating (adapted Mediterranean diet pattern) and increasing physical activity. Potential moderating factors Density of and distance to food and physical activity venues, modified food environment index, Walk Score, crime, and perceived nutrition and physical activity neighborhood barriers were the potential mediating factors. Outcome measures Diet quality, physical activity, and weight loss were the outcomes measured. Statistical analyses Statistical analyses included correlation and linear regression and controlling for potential confounders (baseline values of the dependent variables, age, race, education, and sex). Results In adjusted analysis, there was an inverse association between weight change and the food environment, suggesting that participants who lived in a less-healthy food environment lost more weight during the 6-month intervention period ($P=0.01$). Also, there was a positive association between self-reported physical activity and distance

to private gyms ($P=0.04$) and an inverse association between private gym density and pedometer-measured steps ($P=0.03$), indicating that those who lived farther from gyms and in areas with lower density of gyms had greater increases in physical activity and steps, respectively. Contrary to our hypotheses, results indicated that those living in less favorable food and physical activity environments had greater improvements in diet, physical activity, and weight, compared to those living in more favorable environments. Additional research should be undertaken to address these paradoxical findings and, if confirmed, to better understand them. [Pitts, Stephanie B. Associations of Evolutionary-Concordance Diet and Lifestyle Pattern Scores with Incident, Sporadic Colorectal Adenoma in a Pooled Case-Control Study NUTRITION AND CANCER-AN INTERNATIONAL JOURNAL English Article

RESEARCH FUND/AMERICAN INSTITUTE; CANCER PREVENTION RECOMMENDATIONS; MEDITERRANEAN DIET; COLON-CANCER; REDUCED RISK; OXIDATIVE BALANCE; PHYSICAL-ACTIVITY; ADHERENCE; INDEX; GUIDELINES Differences in diet and lifestyle relative to those of our Paleolithic-era ancestors may explain current high incidences of chronic diseases, including colorectal cancer (CRC), in Westernized countries. Previously reported evolutionary-concordance diet and lifestyle pattern scores, reflecting closeness of diet and lifestyle patterns to those of Paleolithic-era humans, were associated with lower CRC incidence. Separate and joint associations of the scores with colorectal adenoma among men and women are unknown. To address this, we pooled data from three case-control studies of incident, sporadic colorectal adenomas (n = 771 cases, 1,990 controls), used participants' responses to food frequency and lifestyle questionnaires to calculate evolutionary-concordance diet and lifestyle pattern scores, and estimated the scores' associations with adenomas using multivariable unconditional logistic regression. The multivariable-adjusted odds ratios comparing those in the highest relative to the lowest diet and lifestyle score quintiles were 0.84 (95% confidence interval [CI] 0.62, 1.12; P-trend:0.03) and 0.41 (95% CI 0.29, 0.59; P-trend:<0.0001), respectively. The inverse associations were stronger for high-risk adenomas, and among those with both high relative to those with both low diet and lifestyle scores. These results suggest that more evolutionary-concordant diet and lifestyle patterns, separately and jointly, may be associated with lower risk for incident, sporadic colorectal adenoma. Supplemental data for this article is available online at

cytochrome P4502D6 gene in the Moroccan population EGYPTIAN
JOURNAL OF MEDICAL HUMAN GENETICS English Article

Polymorphism; Moroccan
population; PCA DRUG-METABOLIZING-ENZYMES; BREAST-CANCER
PATIENTS; CYP2D6 GENE; MOLECULAR DIVERSITY; HIGH-FREQUENCY;
ALLELE; PHARMACOGENETICS; TAMOXIFEN; CYP2C19; GENOTYPES
Background The CYP2D6 gene encodes a crucial enzyme involved
in the metabolic pathways of many commonly used drugs. It is a
highly polymorphic gene inducing an interethnic and
interindividual variability in disease susceptibility and
treatment response. The aim of this study is to evaluate the
frequency of the three CYP2D6 most investigated alleles (CYP2D6*3,
CYP2D6*4, and CYP2D6*10 alleles) in Morocco compared to other
populations. This study enrolled 321 healthy Moroccan subjects.
CYP2D6 genotypes and allele frequencies were assessed using a
restriction fragment length polymorphism-polymerase chain reaction
genotyping method. The Principal Component Analysis (PCA) and
dendrogram were conducted to evaluate genetic proximity between
Moroccans and other populations depending on CYP2D6 allele
frequencies. Results According to the current study, the results
observed the homozygous wild type of the three studied SNPs were
predominant among the Moroccan population, while 1.4% of Moroccans
carried the CYP2D6*4 allele responsible for a Poor Metabolizer
phenotype and associated with low enzyme activity which may induce
a treatment failure. The PCA and cluster dendrogram tools revealed
genetic proximity between Moroccans and Mediterranean, European
and African populations, versus a distancing from Asian
populations. Conclusion The distribution of CYP2D6 polymorphisms
within Morocco follows the patterns generally found among the
Mediterranean, European and African populations. Furthermore,
these results will help to lay a basis for clinical studies, aimed
to introduce and optimize a personalized therapy in the Moroccan
population. [El Akil, Soumaya; Elouilamine, Ezohra; Ighid,

 CARCINOMA; CHEMOKINE RECEPTOR CCR4; TOLL-LIKE RECEPTOR-3;
 CIGARETTE-SMOKING; BREAST-CANCER; MALIGNANT-TRANSFORMATION;
 TOBACCO SMOKING; POOR-PROGNOSIS; IFN-GAMMA Water-pipe smoking
 (WPS) is becoming the most popular form of tobacco use among the
 youth, especially in the Middle East, replacing cigarettes rapidly
 and becoming a major risk of tobacco addiction worldwide. Smoke
 from WPS contains similar toxins as those present in cigarette
 smoke and is linked directly with different types of cancers
 including lung and head and neck (HN) carcinomas. However, the
 underlying molecular pathways and/or target genes responsible for
 the carcinogenic process are still unknown. In this study, human
 normal oral epithelial (HNOE) cells, NanoString PanCancer Pathways
 panel of 770 gene transcripts and quantitative real-time
 polymerase chain reaction (qRT-PCR) analysis were applied to
 discover differentially expressed genes (DEG) modulated by WPS. In
 silico analysis was performed to analyze the impact of these genes
 in HN cancer patient's biology and outcome. We found that WPS can
 induce the epithelial-mesenchymal transition (EMT: hallmark of
 cancer progression) of HNOE cells. More significantly, our
 analysis of NanoString revealed 23 genes deregulated under the
 effect of WPS, responsible for the modulation of cell cycle,
 proliferation, migration/invasion, apoptosis, signal transduction,
 and inflammatory response. Further analysis was performed using
 qRT-PCR of HNOE WPS-exposed and unexposed cells supported the
 reliability of our NanoString data. Moreover, we demonstrate those
 DEG to be upregulated in cancer compared with normal tissue. Using
 the Kaplan-Meier analysis, we observed a significant association
 between WPS-deregulated genes and relapse-free survival/overall
 survival in HN cancer patients. Our findings imply that WPS can
 modulate EMT as well as a set of genes that are directly involved
 in human HN carcinogenesis, thereby affecting HN cancer patients'

survival. The Greeks in the West: genetic signatures of the Hellenic colonisation in southern Italy and Sicily EUROPEAN JOURNAL OF HUMAN GENETICS English Article

Y-CHROMOSOME; POPULATION; ADMIXTURE; LINEAGES; MUTATIONS; DIVERSITY; MODELS; PAIR; TIME; WAVE Greek colonisation of South Italy and Sicily (Magna Graecia) was a defining event in European cultural history, although the demographic processes and genetic impacts involved have not been systematically investigated. Here, we combine high-resolution surveys of the variability at the uni-parentally inherited Y chromosome and mitochondrial DNA in selected samples of putative source and recipient populations with forward-in-time simulations of alternative demographic models to detect signatures of that impact. Using a subset of haplotypes chosen to represent historical sources, we recover a clear signature of Greek ancestry in East Sicily compatible with the settlement from Euboea during

the Archaic Period (eighth to fifth century BCE). We inferred moderate sex-bias in the numbers of individuals involved in the colonisation: a few thousand breeding men and a few hundred breeding women were the estimated number of migrants. Last, we demonstrate that studies aimed at quantifying Hellenic genetic flow by the proportion of specific lineages surviving in present-day populations may be misleading. olive oil; inflammatory bowel disease; intestinal inflammation; animal experimentation; mouse model

LONG-TERM INTAKE; BOWEL-DISEASE; CYTOKINE PRODUCTION; MEDITERRANEAN DIET; COLORECTAL-CANCER; POLYPHENOLS; RISK; COLITIS; CELLS; CARCINOGENESIS Inflammatory bowel disease (IBD) is a multifactorial intestinal disorder characterized by chronic intestinal inflammation. The etiology of IBD is still unclear, although genetic, environmental and host factors have been associated to the disease. Extra-virgin olive oil (EVO) is a central component of the Mediterranean diet and it decreases chronic inflammation by interfering with arachidonic acid and NF-kappa B signaling pathways. Specifically, the different components of EVO are able to confer advantages in terms of health in their site of action. For instance, oleic acid displays a protective effect in liver dysfunction and gut inflammation, whereas phenolic compounds protect colon cells against oxidative damage and improve the symptoms of chronic inflammation in IBD. Given the biological properties of EVO, we investigated whether its administration is

able to confer protection in a mouse model of dextrane sodium sulfate (DSS)-induced colitis. Four EVO cultivars from the Apulian Region of Italy, namely Ogliarola (Cima di Bitonto), Coratina, Peranzana and Cima di Mola, respectively, were used. Administration of EVO resulted in reduced body weight loss in our colitis model. Furthermore, mice treated with Ogliarola, Coratina and Cima di Mola EVO displayed a reduction of rectal bleeding and IL-1 beta, TGF beta, IL-6 gene expression levels. Furthermore, Ogliarola, Coratina and Peranzana EVO administration ameliorated intestinal permeability and histopathological features of inflammation. Our data further validate the well-known positive effects of EVO supplementation in promoting human health and suggest the bona fide contribution of EVO in preventing onset and reducing progression of intestinal inflammation.  Dietary inflammatory index and telomere length in subjects with a high cardiovascular disease risk from the PREDIMED-NAVARRA study: cross-sectional and longitudinal analyses over 5 y
 AMERICAN JOURNAL OF CLINICAL NUTRITION English Article aging; diet; inflammation; telomeres; cardiovascular disease FOOD-FREQUENCY QUESTIONNAIRE; MEDITERRANEAN DIET; COLORECTAL-CANCER; POPULATION; ASSOCIATION; PATTERNS; STRESS; FISH Background: Dietary factors can affect telomere length (TL), a biomarker of aging, through oxidation and inflammation-related mechanisms. A Dietary Inflammatory Index (DIE) could help to understand the effect of the inflammatory potential of the diet on telomere shortening. Objective: This study aimed to determine the association of the DIE with TL and to examine whether diet-associated inflammation could modify the telomere attrition rate after a 5-y follow-up of a Mediterranean dietary intervention. Design: This was a prospective study of 520 participants at high cardiovascular disease risk (mean +/- SD age: 67.0 +/- 6.0 y, 45% males) from the PREDIMED-NAVARRA (PREvencion con Meta MEDiterranea-NAVARRA) trial. Leukocyte TL was measured by quantitative real-time polymerase chain reaction at baseline and after 5y of follow-up. The DII was calculated from self-reported data by using a validated 137-item food-frequency questionnaire. Results: Longer telomeres at baseline were found in participants who had a more anti-inflammatory diet (lowest DII score) (P-trend = 0.012). Longitudinal analyses further showed that a greater anti-inflammatory potential of the diet (i.e., a decrease in the DII) could significantly slow down the rate of telomere shortening. Moreover, the multivariable-adjusted OR for short telomeres (z score <= 20th percentile) was 1.80 (95% CI: 1.03, 3.17) in a comparison between the highest (proinflammatory) and the lowest (anti-inflammatory) DII tertiles. Similarly, a greater DII (greatest proinflammatory values) after a 5-y follow-up was associated with almost a 2-fold higher risk of accelerated telomere attrition compared with the highest decrease in DII (greatest anti-inflammatory values) during this period (P-trend = 0.025). Conclusions: This study showed both cross-sectional and longitudinal associations between the inflammatory potential of the diet and telomere shortening in subjects with a high cardiovascular disease risk. Our findings are consistent with, but

do not show, a beneficial effect of adherence to an anti-inflammatory diet on aging and health by slowing down telomere shortening. These results suggest that diet might play a key role as a determinant of TL through proinflammatory or anti-inflammatory mechanisms. Antiproliferative Activity of Antioxidants-Rich Extracts from *Olea europaea* L. Leaves and Oil Against Six Cancerous Human Cell Lines INTERNATIONAL JOURNAL OF FRUIT SCIENCE

English Article *Olea europaea*; cell lines; colon cancer; lung cancer; anti-proliferation; gene expression; oil extract; chemical analysis
 MEDITERRANEAN DIET; BH3-ONLY PROTEINS; BH3 MIMETICS; OLIVE OIL; PLANT; ANTICANCER; APOPTOSIS; OLEUROPEIN; THERAPY; DISEASE

The present work aims to study the cytotoxic effect of the methanolic extract of leaves and oil of three olive cultivars: Manzanillo, Picual and Koroniki. Against six cancer cell lines, namely MCF-7 and MDA (breast cancer), HepG2 (liver cancer), PC3 (prostate cancer), Caco-2 (colon cancer), and A549 (lung cancer) using the MTT method. The results obtained showed that Manzanillo leaf methanolic extract (LMME) and Manzanillo oil (OMME) gave the highest cytotoxicity with the lowest IC50 against Caco2 and A549 cell lines. To explain this result, the mechanism of action was studied at the chemical, cellular and molecular levels. The chemical composition analysis of LMME and OMME was performed by GC-MAS. Furthermore, phytochemical analysis was performed. In addition to cell cycle analysis and apoptosis induction, the gene expression of three apoptotic genes was measured. The total phenolic contents (TPC) and total flavonoid contents (TFC) of (LMME) were greater than that of (OMME). Both LMME and OMME had arrested cell cycle at G1 phase for each of Caco2 and A549 cells. LMME and OMME induce up regulation of Casp3 and BAX genes and down regulation of Bcl-2 gene. These results indicated that, LMME and OMME had anti-proliferation effect against Caco2 and A549 cells through induction of apoptosis pathway. Further detailed studies are needed to examine the effect of each fraction of whole extract. [Alharbi, Reem M.; Gomah, Nanis H.; Ragab, Wafik S. Comparing Indices of Diet Quality With Chronic
Disease Mortality Risk in Postmenopausal Women in the Women's
Health Initiative Observational Study: Evidence to Inform National
Dietary Guidance AMERICAN JOURNAL OF EPIDEMIOLOGY
English Article diet;
diet quality indices; mortality risk; postmenopausal women;
prospective cohort study BREAST-CANCER; MEDITERRANEAN DIET;
PHYSICAL-ACTIVITY; EATING INDEX; CARDIOVASCULAR-DISEASE; PROCESSED
MEAT; ALL-CAUSE; BIOMARKERS; PATTERNS; SURVIVAL Poor diet
quality is thought to be a leading risk factor for years of life
lost. We examined how scores on 4 commonly used diet quality
indices-the Healthy Eating Index 2010 (HEI), the Alternative
Healthy Eating Index 2010 (AHEI), the Alternate Mediterranean Diet
(aMED), and the Dietary Approaches to Stop Hypertension (DASH)-are
related to the risks of death from all causes, cardiovascular
disease (CVD), and cancer among postmenopausal women. Our
prospective cohort study included 63,805 participants in the
Women's Health Initiative Observational Study (from 1993-2010) who
completed a food frequency questionnaire at enrollment. Cox
proportional hazards models were fit using person-years as the
underlying time metric. We estimated multivariate hazard ratios
and 95% confidence intervals for death associated with increasing
quintiles of diet quality index scores. During 12.9 years of
follow-up, 5,692 deaths occurred, including 1,483 from CVD and
2,384 from cancer. Across indices and after adjustment for
multiple covariates, having better diet quality (as assessed by
HEI, AHEI, aMED, and DASH scores) was associated with
statistically significant 18%-26% lower all-cause and CVD
mortality risk. Higher HEI, aMED, and DASH (but not AHEI) scores
were associated with a statistically significant 20%-23% lower
risk of cancer death. These results suggest that postmenopausal
women consuming a diet in line with a priori diet quality indices
have a lower risk of death from chronic disease. [George,

Thymosin β 4 targeting impairs tumorigenic activity of colon cancer stem cells FASEB JOURNAL English

Article actin cytoskeleton; cell cycle; tumor growth; target therapy INTEGRIN-LINKED KINASE; THERAPEUTIC TARGET; EXPRESSION; OVEREXPRESSION; METASTASIS; GENE; SURVIVAL; BETA(4); CYTOSKELETON; CARCINOMA

Thymosin beta 4 (T beta 4) is an actin-binding peptide overexpressed in several tumors, including colon carcinomas. The aim of this study was to investigate the role of T beta 4 in promoting the tumorigenic properties of colorectal cancer stem cells (CR-CSCs), which are responsible for tumor initiation and growth. We first found that CR-CSCs from different patients have higher T beta 4 levels than normal epithelial cells. Then, we used a lentiviral strategy to down-regulate T beta 4 expression in CR-

CSCs and analyzed the effects of such modulation on proliferation, survival, and tumorigenic activity of CR-CSCs. Empty vector-transduced CR-CSCs were used as a control. Targeting of the T beta 4 produced CR-CSCs with a lower capacity to grow and migrate in culture and, interestingly, reduced tumor size and aggressiveness of CR-CSC-based xenografts in mice. Moreover, such loss in tumorigenic activity was accompanied by a significant increase of phosphatase and tensin homologue (PTEN) and a concomitant reduction of the integrin-linked kinase (ILK) expression, which resulted in a decreased activation of protein kinase B (Akt). Accordingly, exogenous expression of an active form of Akt rescued all the protumoral features lost after T beta 4 targeting in CR-CSCs. In conclusion, T beta 4 may have important implications for therapeutic intervention for treatment of human colon carcinoma.-

Juglans regia L. Walnut Extract Against Oxidative DNA Damage
PLANT FOODS FOR HUMAN NUTRITION English
Article Juglans regia L.;
Keratinocytes; Oxidative stress; DNA damage COLORECTAL-CANCER;
TREE NUTS; ANTIOXIDANT; CONSUMPTION; NUTRITION; RADICALS; DISEASE;
ASSAY; RISK; MICE Walnuts (Juglans regia L.) are relevant
components of the Mediterranean diet providing important
macronutrients, micronutrients and other bioactive constituents
including unsaturated fatty acids, proteins, fiber, vitamins,
minerals, phytosterols and polyphenols. Although the walnut
beneficial effects in human health are widely recognized by a lot
of epidemiologic studies very little is known regarding its effect
on damaged DNA. The aim of the present study was to investigate
the effect of Juglans regia L. ethanolic extract from kernel on
the induction of DNA strand breaks by thiol/Fe³⁺/O₂ mixed
function oxidase, tert-butyl hydroperoxide or UVC radiations in
acellular and cellular models. Plasmid DNA cleavage and fast Halo
assay were used to monitor oxidative damage to DNA. Both
approaches showed protection of oxidatively injured DNA. These
results agree with a lot of scientific proofs which recommend
walnut as dietary adjunct in health promotion and prevention as
well as in treatment of lifestyle-related oxidative diseases.

Cancer; Molecular chaperones; Heat shock proteins; Extracellular vesicles; Liquid biopsy CELL-DERIVED EXOSOMES; MOLECULAR CHAPERONES; BREAST-CANCER; MULTIVESICULAR BODIES; MEDIATED ENDOCYTOSIS; ACTIVATED PLATELETS; PROSTATE-CANCER; VESICLES; MEMBRANE; RELEASE In cancer, human cells lose the ability to properly control the series of events that occur constantly during cell growth and division, including protein expression, stability, and dynamics. Heat shock proteins (Hsps) are key molecules in these events, constitutively expressed at high levels and could furthermore be induced by the response to cancer-induced stress. In tumor cells, Hsps have been shown to be implicated in the regulation of apoptosis, immune responses, angiogenesis and metastasis; in some cases, they can be overexpressed and dys-regulated, representing important cancer hallmarks. In the past few years, it has been demonstrated that Hsps can be released by tumor cells through several secreting pathways, including the extracellular vesicles (EVs), thus modulating the tumor microenvironment as well as long-distance intercellular communication and metastati-zation. In this review, we discuss the role of extracellular Hsps in cancer, with a particular interest in Hsps in EVs. We would also like to highlight the importance of fully understanding of the role of extracellular Hsps released by EVs and encourage further research in this field the use of Hsps as early cancer biomarkers and therapeutic targets. Concomitant supplementation of lycopene and
eicosapentaenoic acid inhibits the proliferation of human colon
cancer cells JOURNAL OF NUTRITIONAL BIOCHEMISTRY
English Article Lycopene;
Eicosapentaenoic acid; Akt; mTOR; Proliferation; Colon cancer
cells POLYUNSATURATED FATTY-ACIDS; BREAST-CANCER; PPAR-GAMMA;
TRANSCRIPTIONAL REGULATION; CARCINOMA-CELLS; BETA-CAROTENE; N-3;
PATHWAY; GROWTH; APOPTOSIS Several studies indicated that people
who live in the Mediterranean region have very low rates of
chronic diseases such as cardiovascular disease and cancer. It is
well known that Mediterranean-style diet is rich in vegetables,
tomato, fruit, fish and olive oil. These important dietary
components may contribute to lower risk of cancer. Lycopene, a
major component in tomato, exhibited potential anticarcinogenic
activity Previous studies showed that consumption of fish
containing eicosapentaenoic acid (EPA) correlated with reduced
risk of cancer. However, the combined effects of lycopene and EPA
on the proliferation of human colon cancer have not been studied
well yet. Thus, we investigated the anticancer properties and
therapeutic potential of lycopene and EPA in human colon cancer
HT-29 cells. In this study, we determined the combined effects of
lycopene and EPA on the proliferation of human colon cancer HT-29
cells. We demonstrated that low concentration of lycopene and EPA
could synergistically inhibit the proliferation of colon cancer
cells. The inhibitory mechanism was associated with suppression of
phosphatidylinositol 3-kinase/Akt signaling pathway. Furthermore,
treatment of lycopene and EPA also synergistically blocked the
activation of downstream mTOR molecule. Immunocytochemical
staining results revealed that lycopene and EPA could also up-
regulate the expression of apoptotic proteins such as Bax and Fas
ligand to suppress cell survival. In conclusion, our novel
findings suggest that lycopene and EPA synergistically inhibited
the growth of human colon cancer HT-29 cells even at low
concentration. The inhibitory effects of lycopene and EPA on cell
proliferation of human colon cancer HT-29 cells were, in part,
associated with the down-regulation of the PI-3K/Akt/mTOR
signaling pathway. (C) 2009 Elsevier Inc. All rights reserved.

Comparative Study of Healthy Dietary Patterns for Incident and
Fatal Digestive System Cancer AMERICAN JOURNAL OF
GASTROENTEROLOGY English Article

dietary pattern; digestive system cancer;
gastrointestinal cancer; superior diet; prospective cohort
DIABETES-PREVENTION DIET; CAUSE-SPECIFIC MORTALITY; CHRONIC
LIVER-DISEASE; HIGH-QUALITY DIETS; PANCREATIC-CANCER;
HEPATOCELLULAR-CARCINOMA; COLORECTAL-CANCER; REDUCED RISK; WEIGHT-
GAIN; INDEX INTRODUCTION: We examined multiple dietary patterns in
relation to total digestive system cancer (DSC) incidence and
death. METHODS: A total of 213,038 health professionals from the
Health Professionals Follow-up Study (1986-2016), the Nurses'
Health Study (1986-2018), and the Nurses' Health Study II (1991-
2017) with no cancer diagnosis at baseline were analyzed. DSC
incidence and death were estimated using time-varying Cox
proportional hazards regression models. RESULTS: During up to 32
years of follow-up, 5,724 DSC cases accrued. Adherence to 8
healthy diet patterns was associated with a 7%-13% lower risk of
DSC, particularly for digestive tract cancers. An inverse
association with gastrointestinal tract cancer was also shown for
all pattern scores except Alternate Mediterranean Diet and the
healthful Plant-based Diet Index, with hazard ratios between 0.84
and 0.89. Inverse associations were shown for the reversed
empirical dietary index for hyperinsulinemia (hazard ratio for
90th vs 10th percentile 0.64, 95% confidence interval [CI] 0.47-
0.87) and the empirical dietary index associated with lower
inflammation (rEDIP) (0.53, 95% CI 0.39-0.72) for stomach cancer,
and for the rEDIP (0.58, 95% CI 0.37-0.92) for small intestine
cancer. Among accessory cancers, the Alternate Healthy Eating
Index-2010, alternate Mediterranean diet, and diabetes risk
reduction diet were associated with a 43%-51% lower risk of liver
cancer. The reversed empirical dietary index for hyperinsulinemia,
rEDIP, and the Alternate Healthy Eating Index-2010 were inversely
associated with the risk of fatal DSC. DISCUSSION: Adherence to
healthy diets was associated with a lower risk of incident and
fatal DSC, although the magnitude of the association varied
slightly among the patterns. [Kim, Jihye] Kyung Hee Univ, Coll Life

The Attitudes of Parents Working in the Health
Sector About Their Children to be Vaccinated for Human Papilloma
Virus MEDITERRANEAN JOURNAL OF INFECTION MICROBES AND
ANTIMICROBIALS English Article

Human papilloma virus; vaccination; healthcare
workers ADOLESCENTS Introduction: Human papilloma virus (HPV)
is the most common viral infection of the urogenital system in men
and women. Despite the high protection rate of HPV vaccine,
vaccination rates in our country remain below the optimal level.
The aim of this study is to determine the attitudes of parents
working in the health sector towards having their children
vaccinated against HPV. Materials and Methods: The universe of the
research was formed by all employees of Istanbul Kosuyolu High
Specialization Training and Research Hospital. The questionnaire
consisting of 21 questions was applied to a total of 151 people by
face to face method. Results: One hundred and fifty one employees
working in Kosuyolu High Specialization Training and Research
Hospital were included in the study. Of the employees, 68.9% of
whom were women, 18 (11.9%) stated that they had HPV vaccine. Only
two employees responded positively to the question of whether
their children had HPV vaccine; 27 of them (17.9%) were found to
be thinking of having their children vaccinated against HPV in the
future. When employees were asked why they did not want ttheir
children to be vaccinated against HPV, most (33.8%) stated that
the vaccine was expensive, while 17.2% thought that the vaccine
was not protective. Conclusion: Diseases caused by HPV, especially
cervical cancer, can be prevented by vaccination. It is thought
that this disease can be prevented by vaccination as well as
sexual health education and the use of condoms. However, there may
be a negative attitude towards vaccination among healthcare
professionals. In terms of public health, it is thought that
increasing education on this issue will positively affect both
employees and the public. [Ates, Sebahat] Maltepe Univ, Sch

 and activity pattern in a panel of tumour cell lines propose
 linalyl acetate as a protein kinase/NF- κ B inhibitor GENE
 THERAPY AND MOLECULAR BIOLOGY English Article
 Linalyl acetate; NF-kappa B;
 Connectivity Map HISTONE DEACETYLASE INHIBITORS; EAST
 MEDITERRANEAN SAGE; MULTIPLE-MYELOMA CELLS; NECROSIS-FACTOR-ALPHA;
 P38 MAP KINASE; IN-VITRO; DRUG-RESISTANCE; ANTIINFLAMMATORY
 ACTIVITY; CARDIAC-GLYCOSIDES; SALVIA-LIBANOTICA The essential
 oil of Lebanese sage, *Salvia libanotica*, was reported to have
 anti-tumour activity; however, the mechanism of action has not
 been identified yet. In this study, 14- cancer cell lines
 including drug-sensitive and resistant lung, leukaemia, and colon,
 as well as primary human tumours of chronic lymphocytic leukaemia
 (CLL) and primary normal mononuclear cells (PBMcs) were used to
 characterize the anti-tumour activity and mechanism of action of
 linalyl acetate, a component of the Lebanese sage essential oil.
 Drug activity and gene expression data sets were utilized to
 identify drugs with similar activity patterns and genes involved
 in drug sensitivity/resistance. In addition, the Connectivity Map,
 a gene expression signature-based screening approach, assisted in
 predicting further the molecular action of linalyl acetate. Small
 cell lung carcinoma and colorectal cancer cell lines were the most
 sensitive to the drug and greater tumour selectivity was observed
 against chronic lymphocytic leukaemia cells compared to normal
 mononuclear cells. Only limited effect of some of the classical
 mechanisms of multi-drug resistance on the activity of Linalyl
 acetate was noted which makes it potentially interesting for drug-
 resistant patients. There was high similarity between the
 activity-pattern/gene expression profile of linalyl acetate and
 that of protein kinase/NF-kappa B inhibitors. Validating this,
 linalyl acetate was found to strongly inhibit Janus kinase, JAK3,
 and p38 alpha kinases in a cell-free assay as well as the NF-kappa
 B translocation in a dose-dependent manner. Taken together, our
 results show that the NF-kappa B inhibitor, linalyl acetate, may
 represent a new therapeutic compound in the management of
 inflammation and cancer. [Hassan, Saadia Bashir; Lindhagen,

J Park, SY; Kang, M; Shvetsov, YB; Setiawan, VW; Boushey, CJ; Haiman, CA; Wilkens, LR; Le Marchand, L Park, Song-Yi; Kang, Minji; Shvetsov, Yurii B.; Setiawan, Veronica Wendy; Boushey, Carol J.; Haiman, Christopher A.; Wilkens, Lynne R.; Le Marchand, Loic Diet quality and all-cause and cancer-specific mortality in cancer survivors and non-cancer individuals: the Multiethnic Cohort Study EUROPEAN JOURNAL OF NUTRITION English Article

Cancer survivors; Cohort; Diet quality; Mortality; Multiethnic population STOP HYPERTENSION SCORE; HEALTHY EATING INDEX; BREAST-CANCER; MEDITERRANEAN DIET; PHYSICAL-ACTIVITY; RISK; METAANALYSIS; PATTERNS; NUTRITION; OUTCOMES Purpose We examined post-diagnostic diet quality in relation to all-cause and cancer-specific mortality among adults diagnosed with invasive cancer between cohort entry (45-75 years) and their 10-year follow-up, in comparison with those without invasive cancer during that period, in the Multiethnic Cohort. Methods Data were from 70,045 African Americans, Native Hawaiians, Japanese Americans, Latinos, and Whites (6370 with cancer, 63,675 without cancer). Diet quality was measured by the Healthy Eating Index (HEI)-2015, the Alternative HEI-2010 (AHEI-2010), the alternate Mediterranean Diet (aMED), and the Dietary Approaches to Stop Hypertension (DASH) scores, using a food frequency questionnaire. Multivariable Cox models estimated the association of the dietary indexes at 10-year follow-up and changes since baseline with subsequent mortality. Results Post-diagnostic scores from all four indexes were associated with lower mortality: for the highest vs. lowest quartiles, hazard ratio (HR) for all-cause mortality was 0.74 (95% CI 0.67-0.82) for HEI-2015, 0.82 (0.74-0.92) for AHEI-2010, 0.74 (0.66-0.84) for aMED, and 0.82 (0.74-0.91) for DASH. The corresponding HRs for cancer mortality were 0.84 (0.71-1.00), 0.85 (0.71-1.00), 0.71 (0.59-0.85), and 0.84 (0.71-1.00). Compared to stable scores over 10 years (< 0.5 SD change), HR for all-cause mortality was 0.87 (0.79-0.97) for ≥ 1 SD increase in HEI-2015 and was 1.22 to 1.29 for ≥ 1 SD decrease in scores across the four indexes. These HRs were similar to those for participants without cancer. Conclusion Post-diagnostic high-quality diet was related to lower all-cause and cancer mortality among adult cancer survivors, with risk reduction comparable to that among participants without cancer.

Article bladder cancer; diet quality; multiethnic population; cohort study COLORECTAL-CANCER; ADHERENCE; INDEXES; HAWAII; FIBER This study analyzed the overall quality of the diet using predefined indices, including the Healthy Eating Index-2015 (HEI-2015), the Alternative Healthy Eating Index-2010 (AHEI-2010), the alternate Mediterranean Diet (aMED) score, the Dietary Approaches to Stop Hypertension (DASH) score, and the Dietary Inflammatory Index (DII (R)), to explore their association with the risk of bladder cancer in the Multiethnic Cohort Study. Data were taken from 186,979 African American, Japanese American, Latino, Native Hawaiian, and non-Hispanic White participants aged 45-75 years, with 1152 incident cases of invasive bladder cancer during a mean follow-up period of 19.2 +/- 6.6 years. Cox models were used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) with comprehensive adjustment for smoking. Comparing the highest vs. lowest diet quality score quintile, HRs (95% CIs) in men was 1.08 (0.86-1.36) for HEI-2015, 1.05 (0.84-1.30) for AHEI-2010, 1.01 (0.80-1.27) for aMED, 1.13 (0.90-1.41) for DASH, and 0.96 (0.76-1.21) for DII (R), whereas the corresponding HRs for women were 0.75 (0.53-1.07), 0.64 (0.45-0.92), 0.60 (0.40-0.88), 0.66 (0.46-0.95), and 0.63 (0.43-0.90) with all p values for trend <0.05. The inverse association found in women did not vary by smoking status or race and ethnicity. Our findings suggest that adopting high-quality diets may reduce the risk of invasive bladder cancer among women in a multiethnic population. ACTHIV-IST Action Against HIV Ista Prevalence and mortality of cancer among people living with HIV and AIDS patients: a large cohort study in Turkey EASTERN MEDITERRANEAN HEALTH JOURNAL English Article

human immunodeficiency virus; AIDS; cancer; prevalence; mortality ACTIVE ANTIRETROVIRAL THERAPY; INFECTED PATIENTS; HIV/AIDS PATIENTS; IMMUNODEFICIENCY; RISK; MALIGNANCIES; ISTANBUL; CARE; MANAGEMENT; DISEASE Background: Cancer is responsible for elevated human immunodeficiency virus (HIV)-related mortality but there are insufficient data about cancer in HIV-positive patients in Turkey. Aims: We aimed to investigate the prevalence and mortality of cancer among people living with HIV and AIDS patients in Istanbul, Turkey. Methods: Between January 1998 and December 2016, people living with HIV and AIDS patients were enrolled in this study by the ACTHIV-IST Study Group, which consists of 5 centres to follow-up HIV-positive patients in Istanbul. The cancer diagnoses included AIDS-defining cancers (ADCs) and non AIDS-defining cancers (NADCs). Results: Among 1872 patients, 37 (1.9%) were diagnosed with concurrent cancer. Eleven patients were diagnosed during follow-up; the prevalence of cancer among people living with HP/and AIDS patients was 2.6%. Among 48 cancer patients, 35 patients had ADCs, and 32 of them were diagnosed at their first hospital admission. There were 1007 late presenters and 39 of them had cancer (29 were ADCs). The most prevalent NADCs were gastrointestinal, genitourinary, and pulmonary cancers. NADCs were mostly diagnosed during follow-up of patients. The mortality of this group was significantly higher

than that of patients with ADCs (53.9% vs 22.9%). Conclusions: These results indicate the importance of cancer screening at diagnosis and during follow-up of HIV infection. A detailed physical examination contributes to diagnosis of the most prevalent ADCs (Kaposi's sarcoma and non-Hodgkin's lymphoma), especially in late presenters. For NADCs, individual risk factors should be considered. J Ugrakli, S; Ozdemir, M; Gulseren, YD; Findik, S Ugrakli, Selin; Ozdemir, Mehmet; Gulseren, Yasemin Derya; Findik, Siddika Prevalence and Genotype Distribution of High-risk Human Papilloma Virus Types Compared with Cervical CytologyMEDITERRANEAN JOURNAL OF INFECTION MICROBES AND ANTIMICROBIALS English Article HPV; screening; vaccine; cancer CANCER; WOMEN; INFECTION Introduction: Human papilloma virus (HPV) is a well-known causative pathogen of cervical cancer. The distribution of HPV prevalence and genotypes differ between regions. This study aimed to detect the prevalence of high-risk HPV (hrHPV) and genotype distribution among patients with cervical cytology. Materials and Methods: A total of 1,571 women aged 17-91 years who presented to the department of Gynecology and Obstetrics Outpatient Clinic of our hospital, between January 1, 2017, and

July 30, 2019, were included. Samples were collected for cytology and transported to the Medical Microbiology Laboratory for HPV deoxyribonucleic acid (DNA) test. Cervical specimens were investigated for the presence of hrHPV and genotyping of HPV using a commercial kit (Nuclear Laser Medicine S.r.l., Milano, Italy) by real-time polymerase chain reaction. Simultaneously, cytological examination was performed using conventional (Papanicolaou) method and interpreted according to the Bethesda system. Data were analyzed using the Statistical Package for the Social Sciences (SPSS) version 22.0 (SPSS Inc., Chicago, IL, USA). Results: Of the 1,571 women with a mean age of 39.98 (+/- 10.17) years, HPV DNA was negative in 972 (61.9%) patients, while 599 (38.1%) patients were positive for hrHPV. No significant difference was found between age groups in terms of HPV positivity (p=0.18). The most common hrHPV types detected were HPV16 (28.5%), HPV68 (18.7%), HPV51 (15.5%), HPV39 (15.4%), and HPV31 (13.4%), in descending order. Single HPV infections were found in 61.4% (368/599), while infections with multiple HPV genotypes were detected in 38.6% (231/599) of all cases. Conclusion: This study indicated that HPV infection is more prevalent than expected among women living in the central part of Turkey. Additionally, the high prevalence of non-vaccinable genotypes should be considered a regional difference, and the use of this knowledge for guidance in the selection and development prophylactic vaccines may lead to successful broader prevention. Characterization of the Healthy Human Thyroid Tissue and Two Pathological Case Studies PLOS ONE English

Article FLOW DOPPLER

SONOGRAPHY; BLOOD-FLOW; CORRELATION SPECTROSCOPY; FEMALE BREAST; SCATTERING; BENIGN; DIFFERENTIATION; FLUORESCENCE; MANAGEMENT; DIAGNOSIS The in vivo optical and hemodynamic properties of the healthy (n = 22) and pathological (n = 2) human thyroid tissue were measured non-invasively using a custom time-resolved

spectroscopy (TRS) and diffuse correlation spectroscopy (DCS) system. Medical ultrasound was used to guide the placement of the hand-held hybrid optical probe. TRS measured the absorption and reduced scattering coefficients ($\mu(a)$, $\mu(s)'$) at three wavelengths (690, 785 and 830 nm) to derive total hemoglobin concentration (THC) and oxygen saturation (StO_2). DCS measured the microvascular blood flow index (BFI). Their dependencies on physiological and clinical parameters and positions along the thyroid were investigated and compared to the surrounding sternocleidomastoid muscle. The THC in the thyroid ranged from 131.9 μM to 144.8 μM , showing a 25-44% increase compared to the surrounding sternocleidomastoid muscle tissue. The blood flow was significantly higher in the thyroid ($BFI_{thyroid} = 16.0 \times 10^{-9}$ cm^2/s) compared to the muscle ($BFI_{muscle} = 7.8 \times 10^{-9}$ cm^2/s), while StO_2 showed a small (StO_2 , muscle = 63.8% to StO_2 , thyroid = 68.4%), yet significant difference. Two case studies with thyroid nodules underwent the same measurement protocol prior to thyroidectomy. Their THC and BFI reached values around 226.5 μM and 62.8×10^{-9} cm^2/s respectively showing a clear contrast to the nodule-free thyroid tissue as well as the general population. The initial characterization of the healthy and pathologic human thyroid tissue lays the ground work for the future investigation on the use of diffuse optics in thyroid cancer screening.

mortality in hospitalized African American COVID-19 patients with
cancer TRANSLATIONAL CANCER RESEARCH English

Article African Americans;
predictors; mortality; coronavirus disease 2019 (COVID-19);
cancers Background: Coronavirus disease 2019 (COVID-19)
manifest differently depending on patients' background and pre-
existing conditions. It remains unclear how African Americans with
cancer have been affected in comparison to those without. In this
study, we aim to identify demographic, clinical, and laboratory
markers associated with mortality in COVID-19 patients with
cancer. Methods: We reviewed all COVID-19 hospitalized patients'
records from Dec. 2019 to Oct. 2021 at Howard University Hospital.
Patients having a history of, or active, cancer were reviewed.
Clinical, treatment, lab test values, and pathological data were
extracted. Univariable and multivariable analyses were conducted
on the entire cohort as well as on cases and controls separately,
using SPSS software. Results: Out of 512 COVID-19 infected
patients, 49 had cancer, either active or history of cancer
(cases) and 463 COVID-19 were cancer-free (controls), allowing for
comparison. African American race was predominant in both cases
and controls, 83.7% and 66.7% respectively. Cancer patients were
older than non-cancer patients (mean age: 70.6 vs. 56.3 years) and
had an increased length of hospital stay (mean 13.9 vs. 9.4 days).
Mortality is significantly higher among cancer patients (n=10,
20.4%, P=0.03) compared to non-cancer COVID-19 patients (n=41,
8.9%). Among cancer patients, breast cancer was more prevalent in
females and prostate cancer in males (54% and 52%, respectively).
A comparison of patients with active vs. previous cancer showed no
significant difference in the clinical outcome, death vs.
discharge (P=0.34). A higher reduction in albumin level in cancer
cases, from the time of admission to day 5, was significantly
associated with death during the hospital stay compared to those

discharged (n=24, 49.0%, $P<0.001$). In and albumin (n=40, 8.6%, $P=0.02$) have shown an association with increased mortality. Conclusions: Albumin level has an inverse relationship with clinical outcomes among all COVID-19 infected cancer patients. Reduction in albumin level during the hospital stay, particularly in COVID-19 cancer patients should be considered as a predictor of mortality. Further research with a large cohort size is needed to verify and identify other predictors of outcomes in COVID-19 patients with cancer. risk of coronary artery disease: a prospective analysis in 3
cohorts AMERICAN JOURNAL OF CLINICAL NUTRITION

English Article

cardiovascular; diet quality; coronary heart disease;
nutrition; diet MEDITERRANEAN DIET SCORE; ALL-CAUSE MORTALITY;
CARDIOVASCULAR-DISEASE; HEART-DISEASE; FREQUENCY QUESTIONNAIRE;
POSTMENOPAUSAL WOMEN; COLORECTAL-CANCER; NO ASSOCIATION; STYLE
DIET; ADHERENCE Background: Currently, there are few diet quality
assessment tools that are predictive of coronary artery disease
(CAD) risk that do not require nutrient analysis and substantial
time to administer in clinical settings. Objective: To inform the
development of such a tool, we prospectively examined the
association between a food-based diet quality score and risk of
CAD in 3 separate large US cohort studies. Design: Between 1984
and 2012, 71,415 women (aged 43-63 y in 1984), 42,945 men (aged
40-75 y in 1986), and 93,131 younger women (aged 27-44 y in 1991)
without a history of cardiovascular disease were followed up to 28
y. Diet was assessed ≤ 7 times by using repeated food-frequency
questionnaires. We computed the Food Quality Score (FQS) for each
individual based on food groups previously associated with less
weight gain. A higher score represented a healthier diet. The FQS
and CAD association was modeled with the Cox proportional hazard
model, controlling for potential confounders. We also compared the
magnitude of association with CAD for the FQS and other diet
quality scores. Results: We ascertained 6817 incident total CAD
events, with 4588 cases of nonfatal myocardial infarction and 2131
fatal CAD events. Comparing top to bottom deciles, pooled RRs of
the FQS were 0.61 (95% CI: 0.54, 0.69; P-trend < 0.001) for total
CAD. These associations were independent of established
cardiovascular disease risk factors including body weight,
physical activity, and smoking. The magnitude of the RR for 1 SD
of the FQS and CAD was generally similar to established diet
scores that require detailed nutrient analysis, including the
Alternate Healthy Eating Index-2010, the Dietary Approaches to
Stop Hypertension score, and the alternate Mediterranean diet
score. Conclusion: A higher food-based diet quality score was
associated with lower risk of CAD and was comparable with
established diet scores. [Fung, Teresa T.] Simmons Coll, Dept

Sporadic colon cancer: Mismatch repair immunohistochemistry and microsatellite instability in omani subjects DIGESTIVE DISEASES AND SCIENCES English Article MSI; p16; MSP; CRC; Oman UNSTABLE COLORECTAL-CANCER; HMLH1 PROMOTER; CLINICOPATHOLOGICAL FEATURES; AFRICAN-AMERICANS; DNA METHYLATION; CELL-LINES; HYPERMETHYLATION; 5-FLUOROURACIL; CARCINOMA; MUTATION

Background Colorectal carcinoma (CRC) is the most common gastrointestinal malignancy in the world, and there are suggestions of a particularly high incidence in the Middle East, including those of African origin. Defects in DNA mismatch repair (MMR) systems are involved in the carcinogenesis of both sporadic and inherited human cancers. We assessed colonic cancers in an attempt to identify tumors with DNA MMR deficiency and microsatellite instability (MSI). Additionally, we tested the ability of cell cycle regulator p16 that effects cell proliferation and can be abrogated by hypermethylation of the promoter region. Methods We reviewed the charts of 756 patients who were referred to the Oman major colonoscopy unit of the Sultan

Qaboos University Hospital and Royal Hospital from the years 2000 to 2004. Colon cancer tissue was assayed using immunohistochemistry for expression of hMLH1 and hMSH2, and a panel of five pairs of microsatellite primers (NR21, NR22, NR24, BAT25, and BAT26) for MSI-H analysis and additional dinucleotide markers (D17S250, D5S346, and D2S123) used for MSI-L. The expression status of MMR genes and MSI was correlated with cancer stage, location, and histology. A total of 49 tumors were analyzed for histopathology, MSI, and hMLH1/hMSH2 protein expression analysis. The methylation status of the p16 promoter was determined by methylation-specific polymerase chain reaction (PCR). Results The mean age for the carcinomas was 52.2 years and 53% of the patients were male. The majority of the tumors were left-sided. The information currently available indicates that there is an incidence of 4.7% colon cancer (49/1036) and 12.1% (126/1290) colon adenoma among the cases who underwent colonoscopy at these centers. The rate of MSI-H was 12.2% (n = 6), which appears to be the same as previously reported in literature. Eight of 49 tumors (16.3%) were MMR defective by IHC. Defects in the mismatch repair genes hMLH1 and hMSH2 were found in four (66.7%) and two (33.3%) of CRCs MSI-H cases, respectively. Defects in hMLH1 expression in tumors were commonly associated with moderate differentiation. The p16 promoter was methylated in 4% of tumors. Conclusion This is the first genetic study of CRC in this region of the world to demonstrate the incidence of MSI, p16 methylation, and hMLH1 and MSH2 expression in the Omani population. In addition, a relatively high frequency of CRC in younger age groups was noted, which is an important observation. The left-sided preponderance of MMR defective tumors was mostly associated with hMLH1, and with possible loss of hMSH2 expression, an observation that differs from studies on other populations. In conclusion, although the overall rate of CRC is unknown in this region, the frequency of MSI in CRC in this region appears to be the same as in Caucasians in the USA. Association Between a 20-Year Cardiovascular
Disease Risk Score Based on Modifiable Lifestyles and Total and
Cause-Specific Mortality Among US Men and Women JOURNAL OF THE
AMERICAN HEART ASSOCIATION English Article

cohort study; lifestyle; mortality;
prevention; risk score CORONARY-HEART-DISEASE; PRIMARY PREVENTION;
MEDITERRANEAN DIET; PHYSICAL-ACTIVITY; BLOOD-PRESSURE; YOUNG-
ADULTS; STROKE; REPRODUCIBILITY; ADHERENCE; VALIDITY

Background-The previously validated Healthy Heart Score effectively predicted the 20-year risk of cardiovascular disease (CVD). We examine whether the Healthy Heart Score may extend to an association with total and cause-specific mortality. Methods and results-The prospective cohort study investigated 58 319 women (mean age 50.2 years) in the Nurses' Health Study (1984-2010) and 29 854 in men (mean age 52.7 years) in the Health Professionals' Follow-up Study (1986-2010) free of cancer and CVD at baseline. The Healthy Heart Score included baseline current smoking; high body mass index; low physical activity; no or excessive alcohol intake; low intake of fruits and vegetables, cereal fiber, or nuts; and high intake of sugar-sweetened beverages or red/processed meats. There were 19 122 total deaths. Compared with participants in the first quintile of the Healthy Heart Score (lowest CVD risk), participants in the fifth quintile (highest CVD risk) had a pooled hazard ratio of 2.26 (95% confidence interval [CI], 1.53-3.33) for total mortality; 2.85 (95% CI, 1.92-4.23) for CVD mortality, and 2.14 (95% CI, 1.56-2.95) for cancer mortality. Participants in the fifth versus the first quintile also had significantly greater risk of death due to coronary heart disease (3.37; 95% CI, 2.16-5.25), stroke (1.75; 95% CI, 1.02-2.99), lung cancer (6.04; 95% CI, 2.78-13.13), breast cancer (1.45; 95% CI, 1.14-1.86), and colon cancer (1.51; 95% CI, 1.18-1.93). Conclusions-The Healthy Heart Score, composed of 9 self-reported, modifiable lifestyle predictors of CVD, is a potentially useful tool for the counseling of healthy lifestyles that was strongly associated with greater risk of all-cause, CVD, and cancer mortality. Exploring a repurposed candidate with dual hIDO1/hTDO2 inhibitory potential for anticancer efficacy identified through pharmacophore-based virtual screening and in vitro evaluation SCIENTIFIC REPORTS English Article Human Indoleamine 2,3-dioxygenase 1 (hIDO1); Human Tryptophan 2,3-Dioxygenase 2 (hTDO2); Dual inhibitors; Cell cycle arrest; Pitavastatin; Drug repurposing INDOLEAMINE 2,3-DIOXYGENASE; CANCER; PITAVASTATIN; DERIVATIVES; DISCOVERY;

BINDING; STAT3; TDO; IDO Discovering effective anti-cancer agents poses a formidable challenge given the limited efficacy of current therapeutic modalities against various cancer types due to intrinsic resistance mechanisms. Cancer immunochemotherapy is an alternative strategy for breast cancer treatment and overcoming cancer resistance. Human Indoleamine 2,3-dioxygenase (hIDO1) and human Tryptophan 2,3-dioxygenase 2 (hTDO2) play pivotal roles in tryptophan metabolism, leading to the generation of kynurenine and other bioactive metabolites. This process facilitates the de novo synthesis of Nicotinamide Dinucleotide (NAD), promoting cancer resistance. This study identified a new dual hIDO1/hTDO2 inhibitor using a drug repurposing strategy of FDA-approved drugs. Herein, we delineate the development of a ligand-based pharmacophore model based on a training set of 12 compounds with reported hIDO1/hTDO2 inhibitory activity. We conducted a pharmacophore search followed by high-throughput virtual screening of 2568 FDA-approved drugs against both enzymes, resulting in ten hits, four of them with high potential of dual inhibitory activity. For further in silico and in vitro biological investigation, the anti-hypercholesterolemic drug Pitavastatin deemed the drug of choice in this study. Molecular dynamics (MD) simulations demonstrated that Pitavastatin forms stable complexes with both hIDO1 and hTDO2 receptors, providing a structural basis for its potential therapeutic efficacy. At nanomolar (nM) concentration, it exhibited remarkable in vitro enzyme inhibitory activity against both examined enzymes. Additionally, Pitavastatin demonstrated potent cytotoxic activity against BT-549, MCF-7, and HepG2 cell lines (IC₅₀ = 16.82, 9.52, and 1.84 μ M, respectively). Its anticancer activity was primarily due to the induction of G1/S phase arrest as discovered through cell cycle analysis of HepG2 cancer cells. Ultimately, treating HepG2 cancer cells with Pitavastatin affected significant activation of caspase-3 accompanied by down-regulation of cellular apoptotic biomarkers such as IDO, TDO, STAT3, P21, P27, IL-6, and AhR.  MAMMARY TUMORIGENESIS; MEVALONATE PATHWAY; COLON-CANCER; RAS;
 CARCINOGENESIS; PROTEIN; TUMORS; RATS Epidemiologic studies of
 breast and pancreatic cancer in several Mediterranean populations
 have demonstrated that increased dietary intake of olive oil is
 associated with a small decreased risk, or no increased risk, of
 cancer, despite a high overall lipid intake. Experimental animal
 models in high dietary fat and cancer also indicate that olive oil
 either has no effect, or a protective effect, on the prevention of
 a variety of chemically induced tumors. As a working hypothesis,
 it is proposed that the high squalene content of olive oil, as
 compared to other human foods, is a major factor in the cancer-
 risk reducing effect of olive oil. Experiments in animal models
 suggest a tumor-inhibiting role for squalene. A mechanism is
 proposed for the tumor-inhibitory activity of squalene based on
 its known strong inhibitory activity of HMG-COA reductase
 catalytic activity in vivo, thus reducing farnesyl pyrophosphate
 (FPP) availability for "prenylation" of ras oncogene, which
 relocates this oncogene to cell membranes and is required for the
 signal-transducing function of ras. Reduction of mutated ras
 oncogene activation may be useful in breast and Colon Cancer and
 may be particularly applicable to pancreatic cancers that are
 strongly associated with ras oncogenes. Rutgers State Univ, Coll

Changes in Serum and Salivary Proteins in Canine Mammary Tumors ANIMALS English Article

biomarker; cancer; canine mammary tumors; dog; proteomics; saliva; serum C-REACTIVE PROTEIN; HUMAN TISSUE KALLIKREINS; PROTEOMIC ANALYSIS; S100A4 P9KA; BREAST; DOGS; OVARIAN; BIOMARKERS; METASTASIS; EXPRESSION Simple Summary The present study describes for the first time the differences in the serum and saliva proteomes between healthy bitches and bitches with mammary tumors using a high-throughput proteomic approach. More than 1000 proteins were identified and 35 in serum and 49 in saliva were significantly modulated. Additionally, their related pathways were discussed in order to improve understanding of the pathophysiology of the disease and one protein, serum albumin, was further validated. The results of the present study could be a source of potential biomarkers for canine mammary tumors in saliva and serum and increase the knowledge on the pathophysiology of the disease. Abstract The aim of this study was to evaluate changes in serum and saliva proteomes in canine mammary tumors (CMT) using a high-throughput quantitative proteomic analysis in order to potentially discover possible biomarkers of this disease. Proteomes of paired serum and saliva samples from healthy controls (HC group, n = 5) and bitches with CMT (CMT group, n = 5) were analysed using a Tandem Mass Tags-based approach. Twenty-five dogs were used to validate serum albumin as a candidate biomarker in an independent sample set. The proteomic analysis quantified 379 and 730 proteins in serum and saliva, respectively. Of those, 35 proteins in serum and 49 in saliva were differentially represented. The verification of albumin in serum was in concordance with the proteomic data, showing lower levels in CMT when compared to the HC group. Some of the modulated proteins found in the present study such as haptoglobin or S100A4 have been related to CMT or human breast cancer previously, while others such as kallikrein-1 and immunoglobulin gamma-heavy chains A and D are described here for the first time. Our results indicate that saliva and serum proteomes can reflect physiopathological changes that occur in CMT in dogs and can be a potential source of biomarkers of the disease.  Caco-2 Colon Cancer Cell Viability and CYP2W1 Gene Expression by
 Hesperidin-treated Lactacaseibacillus rhamnosus GG (LGG) Cell-free
 Supernatants ANTI-CANCER AGENTS IN MEDICINAL CHEMISTRY
 English Article
 Colon cancer; hesperidin; Lactacaseibacillus rhamnosus GG;
 cell-free supernatant; probiotics; CYP2W1 CYTOCHROME-P450
 ENZYMES; COLORECTAL-CANCER; GUT MICROBIOTA; ANTIOXIDANT;
 INHIBITORS; BACTERIA; TUMORSBackground and Objective: Ensuring
 colon homeostasis is of significant influence on colon cancer and
 delicate balance is maintained by a healthy human gut microbiota.
 Probiotics can modulate the diversity of the gut microbiome and
 prevent colon cancer. Metabolites/byproducts generated by
 microbial metabolism significantly impact the healthy colonic

environment. Hesperidin is a polyphenolic plant compound well known for its anticancer properties. However, low bioavailability of hesperidin after digestion impedes its effectiveness. CYP2W1 is a newly discovered oncofetal gene with an unknown function. CYP2W1 gene expression peaks during embryonic development and is suddenly silenced immediately after birth. Only in the case of some types of cancer, particularly colorectal and hepatocellular carcinomas, this gene is reactivated and its expression is correlated with the severity of the disease. This study aimed to investigate the effects of hesperidin-treated *Lactocaseibacillus rhamnosus* GG (LGG) cell-free supernatants on CaCo2 colon cancer cell viability and CYP2W1 gene expression. Methods: Alamar Blue cell viability assay was used to investigate the cytotoxic effect of cell-free supernatant of LGG grown in the presence of hesperidin on CaCo2 cells. To observe the effect of cell-free supernatants of LGG on the expression of CYP2W1 gene, qRT-PCR was performed. Results: Five times diluted hesperidin treated cell-free supernatant (CFS) concentration considerably reduced CaCo2 colon cancer cell viability. Furthermore, CYP2W1 gene expression was similarly reduced following CFS treatments and nearly silenced under probiotic bacteria CFS treatment. Conclusion: The CYP2W1 gene expression was strongly reduced by cell-free supernatants derived from LGG culture, with or without hesperidin. This suggests that the suppression may be due to bacterial byproducts rather than hesperidin. Therefore, the CYP2W1 gene in the case of deregulation of these metabolites may cause CYP2W1-related colon cancer cell proliferation. Associations of key diet-quality indexes with mortality in the Multiethnic Cohort: the Dietary Patterns Methods Project AMERICAN JOURNAL OF CLINICAL NUTRITION

English Article dietary

indexes; epidemiology; multiethnic; risk factors; survival

CORONARY-HEART-DISEASE; MAJOR CHRONIC DISEASE; GUIDELINES-FOR-AMERICANS; ALL-CAUSE MORTALITY; MEDITERRANEAN DIET; CARDIOVASCULAR-DISEASE; COLORECTAL-CANCER; ELDERLY-PEOPLE; BLOOD-PRESSURE; UNITED-STATES

Background: Healthy dietary patterns have been linked positively with health and longevity. However, prospective studies in diverse populations in the United States addressing dietary patterns and mortality are limited. Objective: We assessed the ability of the following 4 diet-quality indexes [the Healthy Eating Index-2010 (HEI-2010), the Alternative HEI-2010 (AHEI-2010), the alternate Mediterranean diet score (aMED), and the Dietary Approaches to Stop Hypertension (DASH)] to predict the reduction in risk of mortality from all causes, cardiovascular disease (CVD), and cancer. Design: White, African American, Native Hawaiian, Japanese American, and Latino adults (n = 215,782) from the Multiethnic Cohort completed a quantitative food-frequency questionnaire. Scores for each dietary index were computed and divided into quintiles for men and women. Mortality was documented over 13-18 y of follow-up. HRs and 95% CIs were computed by using adjusted Cox models. Results: High HEI-2010, AHEI-2010, aMED, and DASH scores were all inversely associated with risk of mortality from all causes, CVD, and cancer in both men and women (P-trend < 0.0001 for all models). For men, the HEI-2010 was consistently associated with a reduction in risk of mortality for all causes (HR: 0.75; 95% CI: 0.71, 0.79), CVD (HR: 0.74; 95% CI: 0.69, 0.81), and cancer (HR: 0.76; 95% CI: 0.70, 0.83) when lowest and highest quintiles were compared. In women, the AHEI and aMED showed large reductions for all-cause mortality (HR: 0.78; 95% CI: 0.74, 0.82), the AHEI showed large reductions for CVD (HR: 0.76; 95% CI: 0.69, 0.83), and the aMED showed large reductions for cancer (HR: 0.84; 95% CI: 0.76, 0.92). Conclusion: These results, in a US multiethnic population, suggest that consuming a dietary pattern that achieves a high diet-quality index score is associated with lower risk of mortality from all causes, CVD, and cancer in adult men and women. Meat consumption in the European
Prospective Investigation into Cancer and Nutrition (EPIC)
cohorts:: results 24-hour dietary recalls PUBLIC HEALTH
NUTRITION English Article

EPIC study; diet; meat; processed meat; 24-hour
dietary recall; Europe COLORECTAL-CANCER; RED MEAT; FOOD;
NUTRIENTS; TRENDS; HABITS; RISK; COUNTRIES; INTERVIEW; AUSTRALIA

Objective: To evaluate meat intake patterns in the European
Prospective Investigation into Cancer and Nutrition (EPIC)
cohorts. Design and setting: 24-Hour dietary recalls were assessed
within the framework of a prospective cohort study in 27 centres
across 10 European countries by means of standardised computer-
assisted interviews. Subjects: In total, 22 924 women and 13 031
men aged 35-74 years. Results: Mean total meat intake was lowest
in the 'health-conscious' cohort in the UK (15 and 21 g day⁻¹) in
women and men, respectively) and highest in the north of Spain,
especially in San Sebastian (124 and 234 g day⁻¹), respectively).
In the southern Spanish centres and in Naples (Italy), meat
consumption was distinctly lower than in the north of these
countries. Central and northern European centres/countries showed
rather similar meat consumption patterns, except for the British
and French cohorts. Differences in the intake of meat sub-groups
(e.g. red meat, processed meat) across EPIC were even higher than
found for total meat intake. With a few exceptions, the
Mediterranean EPIC centres revealed a higher proportion of
beef/veal and poultry and less pork or processed meat than
observed in central or northern European centres. The highest
sausage consumption was observed for the German EPIC participants,
followed by the Norwegians, Swedish, Danish and Dutch.
Conclusions: The results demonstrate distinct differences in meat
consumption patterns between EPIC centres across Europe. This is
an important prerequisite for obtaining further insight into the
relationship between meat intake and the development of chronic
diseases. Tech Univ Munich, Unit Human Nutr & Canc Prevent, D-

The haptoglobin phenotype influences the risk of cutaneous squamous cell carcinoma in kidney transplant patients JOURNAL OF THE EUROPEAN ACADEMY OF DERMATOLOGY AND VENEREOLOGY

English Article

HUMAN-PAPILLOMAVIRUS INFECTION; PREMALIGNANT SKIN-LESIONS;

EPIDERMODYSPLASIA-VERrucIFORMIS; CERVICAL-CANCER; FREE HEMOGLOBIN;
RECIPIENTS; POLYMORPHISM; INDIVIDUALS; ASSOCIATION; MULTICENTER

Background Cutaneous squamous cell carcinoma (SCC) is the most frequent skin cancer after organ transplantation. Currently, the pre-identification of transplant patients at increased risk for non-melanoma skin cancer remains difficult. Objective To investigate the Hp polymorphism as a marker for the identification of a subset of patients with an increased susceptibility to develop SCC/Bowen's disease. Methods Haptoglobin phenotyping was performed with haemoglobin-supplemented starch gel electrophoresis in 300 kidney transplant patients. High-performance gel permeation chromatography was used in case of low serum haptoglobin concentration. Results Cox regression analysis (adjusted for age, gender and Mediterranean origin) showed a significant association of the Hp 1-1 phenotype with a higher risk of SCC/Bowen's disease ($P = 0.035$) and multiple primary SCCs ($P = 0.002$). No significant difference between the Hp phenotypes was found for the development of Bowen's disease and SCCs in the first 10 years following renal transplantation. However, after a follow-up of >10 years, a significant association between the Hp 1-1 phenotype and the occurrence of Bowen's disease and SCC was reported ($P = 0.002$ and $P = 0.001$ respectively). Conclusions This study shows an increased risk for the development of (multiple) SCCs in kidney transplant patients with the Hp 1-1 phenotype. This finding points to the role of Hp 1-1 phenotype as an important predictor in identifying a subset of patients with an increased need for preventive measures and is in agreement with the decreased anti-inflammatory capacity of this phenotype. APPLICATION OF IRON OXIDE NANOPARTICLES IN
CONTEMPORARY EXPERIMENTAL PHYSIOLOGY AND CELL BIOLOGY RESEARCH
REVIEWS ON ADVANCED MATERIALS SCIENCE English
Article DRUG-DELIVERY;
OXIDATIVE STRESS; BREAST-CANCER; SILVER NANOPARTICLES; DAMAGE;
RATS; SYSTEM; MRI Recent findings have suggested that iron

oxide nanoparticles (IONPs) have some exceptional chemical characteristics which make them useful in both experimental physiology and cell biology research. These nanoparticles might be applied as drug delivery systems for anti-cancer and other medications. Also, IONPs might be a valuable part of many novel bioassays in various fundamental medical fields. In recent years, several studies have indicated that IONPs may have certain cytotoxic and genotoxic potential in living systems. During in vitro conditions, IONPs might induce generation of reactive oxygen species and cause oxidative stress in some cell populations. The toxicity of IONPs is not yet fully understood, and additional research is needed to confirm if IONPs have detrimental effects on human health. This short article focuses on the recent developments and trends in the fields of nanomedicine and nanobiology regarding iron oxide nanomaterials and their application in fundamental medical disciplines such as experimental physiology. We discuss our previously published works on structural effects of IONPs and other metallic nanoparticles on cell nucleus in in vitro conditions. We also describe our recent findings regarding the impact of IONPs on certain biophysical properties of subcellular components. Olive fruit extracts inhibit proliferation and induce
apoptosis in HT-29 human colon cancer cells JOURNAL OF NUTRITION
English Article
MITOCHONDRIAL SUPEROXIDE ANIONS; PENTACYCLIC
TRITERPENE ACIDS; COLORECTAL-CANCER; OIL; MELANOMA; LIPIDS; RISK;
DIET Olives and their derivatives represent an important
component of the Mediterranean diet that has been considered to be
protective against cancer. We investigated the effect on cell
proliferation and apoptosis in HT-29 cells of an extract from the
skin of olives composed of pentacyclic triterpenes with the main
components maslinic acid (73.25%) and oleanolic acid (25.75%).
Studies of the dose-dependent effects showed antiproliferative
activity at an EC50 value of 73.96 +/- 3.19 mu mol/L of maslinic
acid and 26.56 +/- 2.55 mu mol/L of oleanolic acid without
displaying necrosis. Apoptosis was confirmed by the microscopic
observation of changes in membrane permeability in 40.9 +/- 3.9%
and detection of DNA fragmentation in 24.5 +/- 1.5% of HT-29 cells
incubated for 24 h with olive fruit extract containing 150 and
55.5 mu mol/L of maslinic and oleanolic acids, respectively.
Caspase-3 was activated in a dose-dependent manner after
incubation for 24 h. The extract containing 200 mu mol/L maslinic
acid and 74 mu mol/L oleanolic acid increased caspase-3-like
activity to 6-fold that of control cells. Programmed cell death
was induced by the intrinsic pathway, as evidenced by the
production of superoxide anions in the mitochondria of cells
treated with olive fruit extracts containing 150 and 55.5 mu mol/L
of maslinic and oleanolic acids, respectively. Our results report
for the first time, to our knowledge, the inhibition of cell
proliferation without cytotoxicity and the restoration of
apoptosis in colon cancer cells by maslinic and oleanolic acids
present in olive fruit extracts. Univ Barcelona, Fac Farm, Dept

J Celik, G; Akca, H; Sen, A Celik, Gurbet;
Akca, Hakan; Sen, Alaattin Investigation of aromatase
inhibition by several dietary vegetables in human non-small cell
lung cancer cell lines TURKISH JOURNAL OF BIOCHEMISTRY-TURK
BIYOKIMYA DERGISI English Article

Aromatase; Aromatase Inhibitors; Non-small
cell lung cancer; Laurus nobilis; Mentha piperita; Crocus sativus
and Allium porrum EPIDERMAL-GROWTH-FACTOR; ESTROGEN-RECEPTOR-
BETA; BREAST-CANCER; HUMAN AROMATASE; EXPRESSION; GENISTEIN;
THERAPY; ALPHA; PHYTOESTROGENS; RESVERATROL Objective: In this
study we have investigated the effect of extracts obtained from
well-known vegetable diets consumed commonly in Mediterranean and
Aegean regions of Turkey on the expression of aromatase at
protein, mRNA and activity levels in human non-small cell lung
cancer cells-PC-3 and PC-14 cell lines. Method: For this purpose,
cytotoxicity was determined by using crystal violet stain. In vivo
and in vitro aromatase activity was determined fluourometrically.
The expression of aromatase in protein and mRNA levels was
detected by Western blotting using anti-hCYP19 and reverse
transcriptase-polymerase chain reaction using suitable primers,
respectively. Result: Extracts obtained from Laurus nobilis,
Mentha piperita, Crocus sativus reduced aromatase activity 32%,
44%, 36% and 42%, 32%, 56% in PC-14 and PC-3 cell lines,
respectively, no significant changes were observed in protein and
mRNA levels. Whereas extract obtained from Allium porrum decreased
aromatase activity and mRNA level only in PC-14 cell lines by 52%
and 2,5-fold, respectively, without significant influence on
aromatase protein level. Conclusion: The results obtained in this
study have shown that Laurus nobilis, Mentha piperita, Crocus
sativus and Allium porrum do contain effective aromatase
inhibitors. Therefore, further studies investigating the content
of these vegetables are necessary to understand the potential role
and mechanism of action of these foods in reducing the risk of
non-small cell lung carcinomas. [Celik, Gurbet; Sen, Alaattin]

consumption of a high-phenol extra-virgin olive oil reduces
oxidative DNA damage in postmenopausal women BRITISH JOURNAL OF
NUTRITION English Article
extra-virgin olive oil; phenols; hydroxytyrosol;
oxidative DNA damage; cancerDENSITY-LIPOPROTEIN OXIDATION; BREAST-
CANCER RISK; ANTIOXIDANT CAPACITY; FOOD GROUPS; IN-VITRO; HUMANS;
DIET; HYDROXYTYROSOL; EXCRETION; CELLS Extra-virgin olive oils
(EVOO), high in phenolic compounds with antioxidant properties,
could be partly responsible for the lower mortality and incidence
of cancer and CVD in the Mediterranean region. The present study
aims to measure oxidative DNA damage in healthy human subjects
consuming olive oils with different concentrations of natural
phenols. A randomised cross-over trial of high-phenol EVOO (high-
EVOO; 592 mg total phenols/kg) v. low-phenol EVOO (low-EVOO; 147
mg/kg) was conducted in ten postmenopausal women in Florence.
Subjects were asked to substitute all types of fat and oils
habitually consumed with the study oil (50 g/d) for 8 weeks in
each period. Oxidative DNA damage was measured by the comet assay
in peripheral blood lymphocytes, collected at each visit during
the study period. Urine samples over 24 h were collected to
measure the excretion of the olive oil phenols. The average of the
four measurements of oxidative DNA damage during treatment with
high-EVOO was 30 % lower than the average during the low-EVOO
treatment (P=0.02). Urinary excretion of hydroxytyrosol and its
metabolite homovanillyl alcohol were significantly increased in
subjects consuming high-EVOO. Despite the small sample size, the
present study showed a reduction of DNA damage by consumption of
an EVOO rich in phenols, particularly hydroxytyrosol. Sci Inst

of Geodia cydonium induces cell cycle block in human mesothelioma
cells ONCOLOGY LETTERS English Article
Geodia cydonium extract; mesothelioma;
antiproliferative effect; cell cycle block; solid-phase extraction
HUMAN BREAST-CANCER; NATURAL-PRODUCTS; IN-VITRO; MARINE;
SPONGE; APOPTOSIS; ARREST; EXPRESSION; INHIBITORS; INDUCTION The
serious side effects caused by chemotherapeutics and the
development of cancer chemoresistance represent the most
significant limitations in the treatment of cancer. Some
alternative approaches have been developed in recent years, which
are based on natural compounds, and have allowed important
advances in cancer therapeutics. During the last 50 years, sponges
have been considered a promising source of natural products from
the marine environment, representing ~30% of all marine natural
products. Among sponges, the Mediterranean species Geodia cydonium
represents a potential source of these type of products with
considerable biotechnological interest as pharmaceutical agents.
The present study demonstrated the antiproliferative effect of an
organic G. cydonium extract (GEOCYDO) against three human
mesothelioma cell lines, MSTO-211H (MSTO), NCI-H2452 (NCI) and
Ist-Mes2 (Mes2), which differ in their sensitivity (MSTO and NCI)
and resistance (Mes2) to standard combined treatment with
cisplatin and piroxicam. To this aim, the activity of the extract
was evaluated by analyzing its effects on cell viability, cancer
properties and cell cycle progression by means of colony formation
assay, cell cycle analysis and protein expression analysis. The
results revealed, in mesothelioma, this extract was able to reduce
self-renewal, cell migration and it could induce cell cycle arrest
in G(0)/G(1) stage, thus blocking cell proliferation. In
conclusion, to the best of our knowledge, the present results
indicated for the first time that GEOCYDO can contain active
compounds able to affect cell proliferation in mesothelioma,
suggesting that it could be considered as a potential novel drug
source for cancer treatment. [Di Meo, Francesco; Cuciniello,

Herskovitz, I; Greenwald, C; Rothschild, BM; Latimer, B;
Dutour, O; Jellema, LM; Wish-Baratz, S Hyperostosis
frontalis interna: An anthropological perspective AMERICAN
JOURNAL OF PHYSICAL ANTHROPOLOGY English Article
hyperostosis frontalis interna;
estrogen; skeletal populations BREAST-CANCER; ESTROGEN
Hyperostosis frontalis interna (HFI) is manifested by the
accretion of bone on the inner table of the frontal bone. Despite
the vast literature on HFI, ambiguity exists as to its etiology,

osteogenesis, demography, and history. This stimulated the present broad-scale study of HFI which included the evaluation of 1,706 early 20th century skulls (1,007 males and 699 females) from the Hamann-Todd and Terry human osteological collections, as well as 2,019 pre-19th century East-Mediterranean, Amerindian, and Central European skulls. In addition, 72 cadavers were dissected for gross inspection and histology. Special attention was paid to the relationship of the brain and meninges to endocranial lesions. HFI is an independent condition, not a symptom of a more generalized syndrome as suggested in the past. It can appear in a variety of forms but each is the result of the same process and probably of the same etiology. Investigators' previous failure to recognize the mild stages of HFI (types A and B) as an early form of the general HFI process led to erroneous statistics and interpretations of observations. HFI should also be considered a phenomenon separate from HCI, hyperostosis cranialis diffusa (HCD), and other endostoses, even when it appears in association with them. To avoid ambiguity and facilitate the description of cranial hyperostoses, uniform nomenclature (HFI, HCD) has been recommended. HFI is rarely seen in historic populations, regardless of geographical origin. It is most commonly found among females and is believed to be associated with prolonged estrogen stimulation. While its magnitude of manifestation and frequency are much higher in females, HFI is not a purely female phenomenon. Males with hormonal disturbances such as atrophic testis were found to manifest HFI type D. HFI is associated with age insofar as it is much less frequent in females under 40 years of age. Although advanced cases of HFI (types C and D) have been observed in individuals as young as 40 years of age, it is more frequently found after age 60. The frequency of HFI type D will not increase from age 60. Type-predicted analysis by cohort reveals significant ethnic differences. Changes in African American (AA) females appear earlier in life and progress more rapidly than in European American (EA) females. Analysis of radiographs shows a discrepancy between the anatomic prevalence of HFI and its radiological recognition, which is very poor for mild cases. This apparently resulted in the misconceptions that HFI is entirely an old-age phenomenon, and that it is exclusively female. Histological analysis shows that the inner table along with the closely attached dural layer play a major role in the osteogenesis of HFI. Contrary to previous models, no evidence for diploe or ectocranial plate involvement was found. Cadaver study suggests that the predilection for the frontal area may be related to an altered blood supply and/or vascular stretching. (C) 1999 Wiley-Liss, Inc.

J Haywood, R; Andrady, C; Kassouf, N; Sheppard, N
Haywood, Rachel; Andrady, Carima; Kassouf, Nick;
Sheppard, Nick Intensity-dependent Direct Solar
Radiation- and UVA-induced Radical Damage to Human Skin and DNA,
Lipids and Proteins PHOTOCHEMISTRY AND PHOTOBIOLOGY
English Article VIVO
HUMAN SKIN; ANTIOXIDANT ENZYMES; HYDROGEN-PEROXIDE; SINGLET
OXYGEN; BREAST-CANCER; VITAMIN-C; IRRADIATION; ULTRAVIOLET;
MELANIN; SUPEROXIDE Skin can be exposed to high-intensity UV-
radiation in hot countries and during sunbed use; however, the
free-radical damage at these intensities is unknown. We used
electron spin resonance spectroscopy to measure free-radical
generation in ex vivo human skin/substitutes +/- the spin-trap 5,5
dimethyl-1-pyrroline N-oxide (DMPO) exposed to solar-irradiation
equivalent to Mediterranean sunlight. Skin-substitutes, model DNA-
photosensitizer systems, lipids and proteins were also irradiated
with low-intensity UVA/visible light. Without DMPO a broad singlet
was detected (using both irradiations) in skin/substitutes, nail-
keratin, tendon-collagen, phospholipid and DNA + melanin or
riboflavin. In addition to lipid-derived (tentatively tert-
alkoxyl/acyl-) and protein radicals detected with DMPO at lower
intensities, isotropic carbon-, additional oxygen- and hydrogen-
adducts were detected in solar-irradiated skin/substitutes at
higher intensities. Carbon-adducts were detected in UVA-irradiated
human skin cells, DNA + melanin or riboflavin and soybean-
phospholipid. Anisotropic protein-adducts, comparable to adducts
in solar-irradiated tendon-collagen, were absent in UVA-irradiated
skin fibroblasts suggesting the trapping of extracellular collagen
radicals. Absence of hydrogen-adducts in fibroblasts implies
formation in the extracellular compartment. We conclude damage at
high intensities is part cellular (carbon- and oxygen-radicals)
and part extracellular (protein- and hydrogen/H+ + e(-)), and skin
substitutes are suitable for sunscreen testing. While UVA
absorption and lipid-oxidation is direct, DNA and protein-
oxidation require photosensitisation. [Haywood, Rachel; Andrady,

A Daily Snack Containing Leafy Green Vegetables,
Fruit, and Milk before and during Pregnancy Prevents Gestational
Diabetes in a Randomized, Controlled Trial in Mumbai, India

JOURNAL OF NUTRITION English Article

randomized controlled trial; food-
based supplement; leafy green vegetables; fruit; milk;
micronutrients; pregnancy; gestational diabetes; India

MICROBIOLOGICAL ASSAY; MEDITERRANEAN DIET; MELLITUS; RISK;
VITAMIN-B-12; METAANALYSIS; WOMEN; INTERVENTIONS; HOMOCYSTEINE;
OVERWEIGHT Background: Prospective observational studies suggest
that maternal diets rich in leafy green vegetables and fruit may
help prevent gestational diabetes mellitus (GDM). Objective: Our
objective was to test whether increasing women's dietary intake of
leafy green vegetables, fruit, and milk before conception and
throughout pregnancy reduced their risk of GDM. Methods: Project
SARAS ("excellent") (2006-2012) was a nonblinded, individually
randomized, controlled trial in women living in slums in the city
of Mumbai, India. The interventions included a daily snack made
from leafy green vegetables, fruit, and milk for the treatment
group or low-micronutrient vegetables (e.g., potato and onion) for
the control group, in addition to the usual diet. Results for the
primary outcome, birth weight, have been reported. Women were
invited to take an oral-glucose-tolerance test (OGTT) at 28-32 wk
gestation to screen for GDM (WHO 1999 criteria). The prevalence of
GDM was compared between the intervention and control groups, and
Kernel density analysis was used to compare distributions of 120-
min plasma glucose concentrations between groups. Results: Of 6513
women randomly assigned, 2291 became pregnant; of these, 2028
reached a gestation of 28 wk, 1008 (50%) attended for an OGTT, and
100 (9.9%) had GDM. In an intention-to-treat analysis, the
prevalence of GDM was reduced in the treatment group (7.3%
compared with 12.4% in controls; OR: 0.56; 95% CI: 0.36, 0.86; P =
0.008). The reduction in GDM remained significant after adjusting
for prepregnancy adiposity and fat or weight gain during
pregnancy. Kernel density analysis showed that this was explained
by the fact that fewer women in the treatment group had a 2-h
glucose concentration in the range 7.5-10.0 mmol/L. Conclusions:
In low-income settings, in which women have a low intake of
micronutrient-rich foods, improving dietary micronutrient quality
by increasing intake of leafy green vegetables, fruit, and/or milk

may have an important protective effect against the development of GDM. This trial was registered at www.controlled-trials.com as ISRCTN62811278. Published in a supplement to The Journal of Nutrition. Do we need preconception nutrition interventions to improve birth outcomes beyond the prevention of neural tube defects? Current knowledge and future directions was presented at the Scientific Sessions and Annual Meeting of the ASN held in Boston, MA, 28 March-1 April 2015. The conference was organized by the ASN, and was sponsored by the Global Nutrition Council (of ASN), with support from the Micronutrient Initiative, an international not-for-profit organization based out of Ottawa, Canada. The Supplement Coordinators for this supplement were Usha Ramakrishnan and Janet C King. Supplement Coordinator Disclosures: Usha Ramakrishnan received research grants from the Micronutrient Initiative to support the project in Vietnam; and has received honorarium and travel reimbursements for presenting at conferences supported by the Nestle Nutrition Institute. Janet C King has received grant support from NIH, USDA, Almond Board of California, California Walnut Commission, Harvest Plus, Nestle Foundation, and the Bill & Melinda Gates Foundation; has served on the advisory board for Con-Agra, ILSI-North American, Alliance for Potato Research and Education; and has received financial

support/honorarium from Kaiser Permanente. Publication costs for this supplement were defrayed in part by the payment of page charges. This publication must therefore be hereby marked "advertisement" in accordance with 18 USC section 1734 solely to indicate this fact. The opinions expressed in this publication are those of the authors and are not attributable to the sponsors or the publisher, Editor, or Editorial Board of The Journal of Nutrition. The trial was funded by the Wellcome Trust, the Medical Research Council (United Kingdom), the Department for International Development, (United Kingdom) the Parthenon Trust (Switzerland), and ICICI Bank Social Initiatives Group (Mumbai, India).  Legumes: A Healthy and Ecological Source of Flavonoids
 CURRENT NUTRITION & FOOD SCIENCE English
 Article BONE-MINERAL

DENSITY; BREAST-CANCER RISK; ARBUSCULAR MYCORRHIZAL FUNGI; EQUOL-PRODUCING BACTERIUM; FOENUM-GRACECUM FENUGREEK; PIGEONPEA CAJANUS-CAJAN; MENOPAUSAL HOT FLUSHES; NOD GENE-EXPRESSION; SOY-ISOFLAVONES; RHIZOBIUM-LEGUMINOSARUM The Leguminosae are the third largest flowering plant family and includes more than 19,000 species, a small part of them considered edible for man and animals. Grain legumes such as soybean, chickpea, pea, lentil, common bean, faba bean or peanut are the main protein source together with cereals in many developing countries. They also form part of the Mediterranean diet and some of them are consumed after microbial fermentation as probiotics. Legumes may be produced in a sustainable way for their ability to fix atmospheric nitrogen in symbiosis with a group of bacteria called rhizobia. In the development of this symbiosis, legume flavonoids play a fundamental role, being excreted by the plant in response to nodulation factors produced by the bacteria. Isoflavones, which are molecules mainly found in legumes, may have beneficial effects on human health, and their use can be of help in the fight against many diseases, including several types of cancer and cardiovascular disorders. In this paper we review the diversity of legumes consumed by the man, the fundamentals of their ecological production and the role of legume flavonoids both in plant-bacteria interactions and human health. Effects of Olive Metabolites on DNA Cleavage Mediated by
Human Type II Topoisomerases BIOCHEMISTRY English
Article MARKET PLANT-
PRODUCTS; TERMINAL PROTEIN GATE; CELL-CYCLE ARREST; COLORECTAL-
CANCER; DESERT PLANTS; GREEN TEA; ALPHA; OIL; HYDROXYTYROSOL;
POISON Several naturally occurring dietary polyphenols with
chemo-preventive or anticancer properties are topoisomerase II
poisons. To identify additional phytochemicals that enhance
topoisomerase II-mediated DNA cleavage, a library of 341
Mediterranean plant extracts was screened for activity against
human topoisomerase α . An extract from *Phillyrea latifolia* L., a
member of the olive tree family, displayed high activity against
the human enzyme. On the basis of previous metabolomics studies,
we identified several polyphenols (hydroxytyrosol, oleuropein,
verbascoside, tyrosol, and caffeic acid) as potential candidates
for topoisomerase II poisons. Of these, hydroxytyrosol,
oleuropein, and verbascoside enhanced topoisomerase II-mediated
DNA cleavage. The potency of these olive metabolites increased 10-
100-fold in the presence of an oxidant. Hydroxytyrosol,
oleuropein, and verbascoside displayed hallmark characteristics of
covalent topoisomerase II poisons. (1) The activity of the
metabolites was abrogated by a reducing agent. (2) Compounds
inhibited topoisomerase II activity when they were incubated with
the enzyme prior to the addition of DNA. (3) Compounds were unable
to poison a topoisomerase II α construct that lacked the N-
terminal domain. Because hydroxytyrosol, oleuropein, and
verbascoside are broadly distributed across the olive family,
extracts from the leaves, bark, and fruit of 11 olive tree species
were tested for activity against human topoisomerase II α .
Several of the extracts enhanced enzyme-mediated DNA cleavage.
Finally, a commercial olive leaf supplement and extra virgin olive
oils pressed from a variety of *Olea europaea* subspecies enhanced
DNA cleavage mediated by topoisomerase II α . Thus, olive
metabolites appear to act as topoisomerase II poisons in complex
formulations intended for human dietary consumption. [Vann,

Exposure of young men to organochlorine pesticides in
Southern Spain ENVIRONMENTAL RESEARCH English
Article endocrine disruptors;
male; pesticides; reproductive health; serum ELECTRON-CAPTURE
DETECTION; ADIPOSE-TISSUE; BREAST-CANCER; POLYCHLORINATED-
BIPHENYLS; HUMAN SERUM; ENVIRONMENTAL CONTAMINANTS; INADVERTENT
EXPOSURE; ANDROGENIC ACTIVITY; GAS-CHROMATOGRAPHY; LONG-ISLAND

It has been hypothesized that endocrine disruptors and especially synthetic estrogenic environmental contaminants (xenoestrogens) are etiologic factors in the global decrease of sperm counts and other problems of the male reproductive tract, including cryptorchidism, hypospadias, and testicular cancer. This possibility has prompted research into the current and historical incidence of these diseases. The largest area of intensive greenhouse agriculture in Europe is near the Mediterranean coast of Southern Spain, where this activity has greatly expanded since the 1960s. We determined and compared levels of 14 organochlorine pesticides in the blood of 220 young males in Southern Spain.

Aldrin, dieldrin, endrin, lindane, methoxychlor, endosulfans, and DDT and its metabolites were identified. Detectable, p'-DDE were found in 96% of serum samples. Among the remaining DDTs, o,p'-DDD was the most prevalent, concentrations of p. detected in 65% of serum samples. Detectable concentrations of endosulfan I or II or their metabolites endosulfan-diol, or -sulfate were found in all samples; endosulfan-diol was the most frequently detected metabolite (92%) followed by sulfate. Results indicate that men of reproductive age in Southern Spain have been and are exposed to organochlorine pesticides. Because many of these chemicals have estrogenic and anti-androgenic activity, further research is warranted to interpret the male reproductive health consequences of this exposure. foods; carbohydrates; descriptive epidemiology; EPIC study; cancer; 24-hour dietary recall; Europe DIABETES-MELLITUS; COLORECTAL-CANCER; DIETARY FIBER; VEGETABLE CONSUMPTION; RESISTANT STARCH; GLYCEMIC LOAD; FECAL BULK; RISK; FRUIT; NUTRITION Objective: To describe the average consumption of carbohydrate-providing food groups among study centres of the European Prospective Investigation into Cancer and Nutrition (EPIC). Methods: Of the 27 redefined EPIC study centres, 19 contributed subjects of both genders and eight centres female

participants only (men, n = 13 031; women, n = 22 924, after exclusion of subjects under 35 and over 74 years of age from the original 36 900 total). Dietary data were obtained using the 24-hour recall methodology using the EPIC-SOFF software. The major sources of dietary carbohydrate were identified, and 16 food groups were examined. Results: The 10-food groups contributing most carbohydrate were bread; fruit; milk and milk products; sweet buns, cakes and pies; potato; sugar and jam; pasta and rice; vegetables and legumes; crispbread; and fruit and vegetable juices. Consumption of fruits as well as vegetables and legumes was higher in southern compared with northern centres, while soft drinks consumption was higher in the north. Italian centres had high pasta and rice consumption, but breakfast cereal, potato, and sweet buns, cakes and pies were higher in northern centres. In Sweden, lower bread consumption was balanced with a higher consumption of crispbread, and with sweet buns' cakes and pies. Overall, men consumed higher-amounts of vegetables and legumes, bread, soft drinks, potatoes, pasta and rice, breakfast cereal and sugar and jam than women, but fruit consumption appeared more frequent in women. Conclusion: The study supports the established idea that carbohydrate-rich foods chosen in northern Europe are different from those in the Mediterranean region. When comparing and interpreting diet-disease relationships across populations, researchers need to consider all types of foods. Olive oil and immune system functions: potential
involvement in immunonutrition GRASAS Y ACEITES
English Article olive
oil; immune system; lymphocytes; cytokines; autoimmune diseases;
infection; immune resistancePOLYUNSATURATED FATTY-ACIDS; DIETARY-
LIPID MANIPULATION; LISTERIA-MONOCYTOGENES INFECTION; HOST
NATURAL-RESISTANCE; KILLER-CELL ACTIVITY; BREAST-CANCER RISK;
FISH-OIL; RHEUMATOID-ARTHRITIS; LYMPHOCYTE FUNCTIONS; MEMBRANE
FLUIDITY Olive oil plays a crucial role as a main component of
the Mediterranean diet, which has shown important benefits for the
human health. According to the current knowledge, the
administration of diets containing olive oil exerts some
beneficial effects on the immune system functions due likely to
the action of oleic acid rather than other substances contained in
this fat. In the last few years, epidemiological, clinical and
experimental studies have evidenced the potential of certain
dietary lipids (containing polyunsaturated or monounsaturated
fatty acids) as modulators of immune system functions due to their
ability to suppress several functions of immune system in both
humans and animals. As a result, these fats have been applied in
the reduction of symptoms from diseases characterized by an
overactivation of the immune system (autoimmune diseases) or in
the reduction of cancer risk. Here, we review several relevant
experimental and clinical data associated with the beneficial
effects of olive oil upon the health, the mechanisms of action and
the immune function susceptible of being be altered by the
administration of dietary lipids and particularly of olive oil. In
addition, we will also discuss the detrimental effects on the
immune system functions caused by the administration of certain
dietary lipids attributed mainly to a reduction of host natural
resistance against infectious microorganisms as well as the
involvement of olive oil diets in the regulation of immune
resistance.Univ Jaen, Microbiol Unit, Dept Hlth Sci, Fac Expt

Oleanolic and maslinic acid sensitize soft tissue sarcoma

cells to doxorubicin by inhibiting the multidrug resistance

protein MRP-1, but not P-glycoprotein JOURNAL OF NUTRITIONAL

BIOCHEMISTRY

English

Article

Triterpenes; Doxorubicin; MRP-1; Drug resistance;

Soft tissue sarcomas COLON-CANCER CELLS; PENTACYCLIC TRITERPENE

ACIDS; NATURAL TRITERPENE; ANTITUMOR-ACTIVITY; BREAST-CANCER;

OLEA-EUROPAEA; OLIVE OIL; APOPTOSIS; CHEMOTHERAPY; EXPRESSION The

pentacyclic triterpenes oleanolic acid (OLA) and maslinic acid

(MLA) are natural compounds present in many plants and dietary

products consumed in the Mediterranean diet (e.g., pomace and

virgin olive oils). Several nutraceutical activities have been

attributed to OLA and MLA, whose antitumoral effects have been

extensively evaluated in human adenocarcinomas, but little is

known regarding their effectiveness in soft tissue sarcomas (STS).

We assessed efficacy and molecular mechanisms involved in the

antiproliferative effects of OLA and MIA as single agents or in

combination with doxorubicin (DXR) in human synovial sarcoma SW982

and leiomyosarcoma SK-UT-1 cells. As single compound, MLA (10-100

mu M) was more potent than OLA, inhibiting the growth of SW982 and

SK-UT-1 cells by 70.3 +/- 1.11% and 68.8 +/- 1.52% at 80 mu M,

respectively. Importantly, OLA (80 mu M) or MLA (30 mu M) enhanced

the antitumoral effect of DXR (0.5-10 mu M) by up to 23-fold. On

the molecular level, efflux activity of the multidrug resistance

protein MRP-1, but not of the P-glycoprotein, was inhibited. Most

probably as a consequence, DXR accumulated in these cells. Kinetic

studies showed that OLA behaved as a competitive inhibitor of

substrate-mediated MRP-1 transport, whereas MLA acted as a non-

competitive one. Moreover, none of both triterpenes induced a

compensatory increase in MRP-1 expression. In summary, OLA or MLA

sensitized cellular models of STS to DXR and selectively inhibited

MRP-1 activity, but not its expression, leading to a higher

antitumoral effect possibly relevant for clinical treatment. (C)

DEMENTIA; RISK; ALLELE; ADHERENCE; DASH

Objectives: To examine the association between long-term adherence to the Dietary Approaches to Stop Hypertension (DASH) diet with cognitive function and decline in older American women. **Design:** Prospective cohort study. **Setting:** The Nurses' Health Study, a cohort of registered nurses residing in 11 US states. **Participants:** A total of 16,144 women from the Nurses' Health Study, aged ≥ 70 years, who underwent cognitive testing a total of 4 times by telephone from 1995 to 2001 (baseline), with multiple dietary assessments between 1984 and the first cognitive examination. DASH adherence for each individual was based on scoring of intakes of 9 nutrient or food components. **Measurements:** Long-term DASH adherence was calculated as the average DASH adherence score from up to 5 repeated measures of diet. Primary outcomes were cognitive function calculated as the average scores of the 4 repeated measures, as well as cognitive change of the Telephone Interview for Cognitive Status score and composite scores of global cognition and verbal memory. **Results:** Greater adherence to long-term DASH score was associated with better average cognitive function, irrespective of apolipoprotein E epsilon 4 allele status [multivariable-adjusted differences in mean z-scores between extreme DASH quintiles = 0.04 (95% confidence interval, CI 0.01-0.07), P trend = .009 for global cognition; 0.04 (95% CI 0.01-0.07), P trend = .002 for verbal memory and 0.16 (95% CI 0.03 -0.29), and P trend = .03 for Telephone Interview for Cognitive Status, P interaction >0.24]. These differences were equivalent to being 1 year younger in age. Adherence to the DASH score was not associated with change in cognitive function over 6 years. **Conclusions:** Our findings in the largest cohort on dietary patterns and cognitive function to date indicate that long-term adherence to the DASH diet is important to maintain cognitive function at older ages. Reproducibility and validity of diet quality scores derived
from food-frequency questionnaires AMERICAN JOURNAL OF

dietary assessment; diet quality scores;
food frequency questionnaire; diet record; validation study

PLANT-BASED DIETS; TOTAL-ENERGY-INTAKE; BREAST-CANCER;
MEASUREMENT ERROR; PATTERN INDEXES; RISK; VALIDATION; BIOMARKERS;
INFLAMMATION; TOCOPHEROL Background: Diet quality scores (DQs) are frequently used to study diet-disease relations but the validity of these scores derived from FFQs has rarely been evaluated. Objectives: To evaluate the validity and reproducibility of 6 commonly used DQs derived from the FFQ, including the Alternate Healthy Eating Index-2010, Dietary Approaches to Stop Hypertension Trial score, alternative Mediterranean diet score, and 3 plant-based diet indices (overall, healthful, and unhealthful). Methods: This analysis included 1394 participants from the Men's Lifestyle Validation Study (N = 652) and the Women's Lifestyle Validation Study (N = 742). Participants completed a 152-item FM at the beginning of the study and 1 y later, as well as completed 2 weighed 7-d dietary records (7DDRs) and donated 2 blood samples 6 mo apart between FFQ assessments. The reproducibility of the FFQs was evaluated by rank intraclass correlation coefficients (ICCs). The validity was assessed by comparing FFQ-derived DQs with those from the average of two 7DDRs using Spearman rank correlation coefficients deattenuated for random measurement error in the 7DDRs ($r(s)$). Furthermore, we calculated the correlations between DQs and plasma biomarkers of diet, including fatty acids, folate, carotenoids, retinol, and α - and γ -tocopherol. Results: Six FFQ-derived DQs demonstrated moderate to high reproducibility (energy-adjusted ICCs: 0.61–0.84) and validity (energy-adjusted, deattenuated $r(s)$ = 0.56–0.80) in both men and women. We consistently observed expected correlations between FFQ-derived DQs with plasma fatty acids, including long-chain n-3 (omega-3) and trans fatty acids, most carotenoids, and gamma-tocopherol ($r(s)$ > 0.2). Conclusions: Our study demonstrates the validity of the FFQ to evaluate overall diet quality using 6 commonly used DQs. In addition, these DQs have qualitatively demonstrated biological relevance, as indicated by their correlations with circulating biomarkers. J de Souza, RJ; Swain, JF; Appel, LJ; Sacks, FM

de Souza, Russell J.; Swain, Janis F.; Appel, Lawrence J.; Sacks, Frank M. Alternatives for macronutrient intake and chronic disease: a comparison of the OmniHeart diets with popular diets and with dietary recommendations AMERICAN JOURNAL OF CLINICAL NUTRITION English Article

LOW-CARBOHYDRATE-DIET;

CARDIOVASCULAR RISK-FACTORS; LOW-FAT DIET; INCIDENT KIDNEY-STONES; HIGH-PROTEIN DIETS; LIFE-STYLE CHANGES; WEIGHT-LOSS; BLOOD-PRESSURE; MONOUNSATURATED FAT; COLORECTAL-CANCER Background: Enhancements to current dietary advice to prevent chronic disease are of great clinical and public health importance. The OmniHeart Trial compared 3 diets designed to reduce cardiovascular disease (CVD) risk - one high in carbohydrate and 2 that replaced carbohydrate with either unsaturated fat or protein. The lower carbohydrate diets improved the CVD risk factors. Several popular diets claiming health benefits emphasize carbohydrate, fat, or protein or various combined approaches. Objective: The objective of this study was to compare the macronutrient contents of the OmniHeart trial diets to those of several popular diets and to evaluate each diet for consistency with national health guidelines. Design: The macronutrient contents of 7-d menu plans from the OmniHeart Study, Dietary Approaches to Stop Hypertension (DASH), Zone, Atkins, Mediterranean, South Beach, and Ornish diets were evaluated for consistency with the US Food and Nutrition Board's Acceptable Macronutrient Distribution Ranges (AMDRs) and with the dietary recommendations of several health organizations. Results: The OmniHeart diets fulfilled the major AMDRs, but, of the popular diets, only the Zone diet did. The OnmiHeart diets were generally consistent with national guidelines to prevent cancer, diabetes, and heart disease, whereas most popular diets had limitations for fulfilling one or more guidelines.

Conclusions: Although the OnmiHeart protein and unsaturated fat diets were superior to the carbohydrate diet in improving CVD risk, all 3 study diets were consistent with national guidelines to reduce chronic disease risk, which suggests that the guidelines might now be fine-tuned to optimize disease prevention. Popular diets vary in their nutritional adequacy and consistency with guidelines for risk reduction. Inadvertent exposure to xenoestrogens in children
TOXICOLOGY AND INDUSTRIAL HEALTH English
Article cryptorchidism;

endocrine-disrupting chemicals; intensive agriculture; pesticides;
xenoestrogens BREAST-CANCER; TESTICULAR CANCER; BISPHENOL-A;
PESTICIDES; CHEMICALS; ESTROGENS; RISK; QUALITY; SEMEN;
ENVIRONMENT This article reviews previous studies and presents new
data on pesticide exposure in order to provide some indications of
the extent and significance of childhood exposure to
xenoestrogens, including pesticides, epoxy resins, and
polycarbonates. After more than four decades of pesticide use,
little is known about their adverse effects on health. There is a
need to address the potential risks associated with the current
contamination of water, soils, and foods in many agricultural
areas. In southeastern Spain, along the Mediterranean coast,
extensive areas alongside residential zones are devoted to
intensive farming in plastic greenhouses, with the use of large
amounts of pesticides. Human tissue samples have been investigated
for pesticide residues. Samples of fat from children living in
farm areas contained a total of 14 pesticides, including lindane,
HCH, heptachlor, aldrin, dieldrin, endrin, endosulfan, o,p'-DDE
and o,p'-DDD, among others. Of the 113 samples studied, 43 were
positive for one or more pesticides, some of which have estrogenic
activity. The number of new substances that mimic the action of
endogenous estrogens is increasing rapidly. These endocrine-
disrupting chemicals are not restricted to pesticides. Several
different compounds used in the food industry, in plasticizers.
and in dental restorations are also estrogenic. The few studies
that have investigated their effects in humans all indicate that
concerns are warranted. If there is indeed an association between
exposure to substances with hormone-disruptive activity and
certain disorders of sexual maturation, the incidence of such
disorders should be greater in areas where exposure to agents with
this activity is high. We used a spatial ecological design to
search for variations in orchidopexy rates and to analyze
relationships between these differences and geographical
variations in exposure to pesticides. Our results are compatible
with a hypothetical association between exposure to hormone-
disruptive chemicals and the induction of cryptorchidism. Several
methodological limitations in the study design make it necessary

to evaluate the results with caution. In conclusion, a closer scrutiny is required to determine whether epoxy resins and polycarbonates contribute, together with estrogenic pesticides, to the exposure of human consumers, especially children, to xenoestrogens. Evaluating the Potential Anticancer Properties of Salvia triloba in Human-Osteosarcoma U2OS Cell Line and Ovarian Adenocarcinoma SKOV3 Cell Line APPLIED SCIENCES-BASEL

English Article Salvia

triloba; osteosarcoma; ovarian cancer; U2OS; SKOV3; RUNX2; FTIR; TLC-UV fractionation; Chou-Talalay method; drug combination; anticancer EPITHELIAL-MESENCHYMAL TRANSITION; LEYDEN CRYSTAL PROTEIN; BREAST-CANCER; PHYTOCHEMICAL CONSTITUENTS; ANTIPROLIFERATIVE ACTIVITY; BIOLOGICAL-ACTIVITIES; HEMOLYTIC-ACTIVITY; GENE-EXPRESSION; OIL COMPOSITION; N-CADHERIN Salvia triloba (S. triloba) is an herb inherently linked to traditional medicine systems in the Eastern Mediterranean region. There is minimal experimental evidence however, regarding the anticancer effects of S. triloba in both osteosarcoma and ovarian cancer. In this study, we investigated the effects of crude (macerated) S. triloba ethanol and acetone leaf extracts on viability, migratory ability, and the expression of genes regulating these activities in U2OS and SKOV3 cells using MTT assay, scratch-wound healing/trans-well migration assay, and RT-qPCR respectively. MTT assay results indicated that the acetone extract significantly reduced both U2OS and SKOV3 cell viability with half-maximal inhibitory concentrations (IC50) of 54.51 +/- 1.10 mu g/mL and 75.96 +/- 1.0237 mu g/mL respectively; these concentrations further displayed negligible hemolytic activity. The combination of acetone extract (19 mu g/mL) and paclitaxel (0.787 mu g/mL) displayed synergy and reduced SKOV3 cell viability by over 90%. Additionally, the trans-well migration assay illustrated that the acetone extract (IC50) inhibited both U2OS and SKOV3 cell

migration by more than 50%. Moreover, *S. triloba* acetone extract significantly downregulated the steady-state mRNA expression of key genes involved in driving select cancer hallmarks. Four fractions were generated from the acetone extract by thin layer chromatography (TLC), and the obtained retention factors (R_f) (ranging from 0.2 to 0.8) suggested a mixture of high and moderately polar compounds whose bioactivities require further investigation. In addition, FTIR measurements of the extract revealed peaks corresponding to OH, aliphatic CH, and ester groups suggesting the presence of phenolic compounds, terpenes, and polysaccharides. Altogether, these results suggest that *S. triloba* possesses potential therapeutic compounds that inhibit cell proliferation and migration, and modulate several genes involved in osteosarcoma and ovarian carcinoma progression. Sargent, DJ; Goldberg, RM; Jacobson, SD; Macdonald, JS; Labianca, R; Haller, DG; Shepherd, LE; Seitz, JF; Francini, G A pooled analysis of adjuvant chemotherapy for resected colon cancer in elderly patients NEW ENGLAND

JOURNAL OF MEDICINE English Article

ADVANCED COLORECTAL-CANCER; BREAST-CANCER; THERAPEUTIC RESPONSE; RANDOMIZED TRIAL; AGE; OLDER; TOXICITY; 5-FLUOROURACIL; FLUOROURACIL; LEVAMISOLE Background: Adjuvant chemotherapy is standard treatment for patients with resected colon cancer who are at high risk for recurrence, but the efficacy and toxicity of such treatment in patients more than 70 years of age are controversial. Methods: We performed a pooled analysis, based on the intention to treat, of individual patient data from seven phase 3 randomized trials (involving 3351 patients) in which the effects of postoperative fluorouracil plus leucovorin (five trials) or fluorouracil plus levamisole (two trials) were compared with the effects of surgery alone in patients with stage II or III colon cancer. The patients were grouped into four age categories of equal size, and analyses were repeated with 10-year age ranges (less than or equal to 50, 51 to 60, 61 to 70, and >70 years), with the same conclusions. The toxic effects measured in all trials were nausea or vomiting, diarrhea, stomatitis, and leukopenia. Patients in the fluorouracil-plus-leucovorin and fluorouracil-plus-levamisole groups were combined for the efficacy analysis but kept separate for toxicity analyses. Results: Adjuvant treatment had a significant positive effect on both overall survival and time to tumor recurrence ($P < 0.001$ for each, with hazard ratios of death and recurrence of 0.76 [95 percent confidence interval, 0.68 to 0.85] and 0.68 [95 percent confidence interval, 0.60 to 0.76], respectively). The five-year overall survival was 71 percent for those who received adjuvant therapy, as compared with 64 percent for those untreated. No significant interaction was observed between age and the efficacy of treatment. The incidence of toxic effects was not increased among the elderly (age >70 years), except for leukopenia in one study. Conclusions: Selected elderly patients with colon cancer can receive the same benefit from fluorouracil-based adjuvant therapy as their younger counterparts, without a significant increase in toxic effects. Assessment of the estrogenicity of the diet of a healthy
female Spanish population based on its isoflavone content FOOD
ADDITIVES AND CONTAMINANTS PART A-CHEMISTRY ANALYSIS CONTROL
EXPOSURE & RISK ASSESSMENT English Article

estrogenicity; diet; isoflavone;
phytoestrogens; healthy Spanish women; exposure FOOD-FREQUENCY
QUESTIONNAIRE; BREAST-CANCER CELLS; PHYTOESTROGEN INTAKE;
MEDITERRANEAN DIET; ANTIESTROGENIC ACTIVITIES; COLORECTAL-CANCER;
RISK; WOMEN; ENDOMETRIAL; EXPRESSION Phytoestrogens are natural
components of plants consumed by humans. The hormonal activity of
these substances has long been known. Various in vitro tests have
demonstrated the agonistic or antagonistic estrogenic activity of
some phytoestrogens. The objective of this study was to estimate
the supply of isoflavones in the diet of a healthy adult female
population and to assess its estrogenic effect. The diet was
assessed by questionnaire and the estrogenicity of the estimated
isoflavone content was tested by E-screen, finding a mean total
estrogenic capacity of 0.129×10^{10} eq.E-2 (12.9pmolday(1)),
corresponding to a daily isoflavone intake of 265.8gday(1). This
study offers a preliminary insight into the phytoestrogen content
of the diet of a healthy active population of Spanish women. The
effects of this additional hormonal burden are highly
controversial, and this approach to estimating dietary
phytoestrogen intake of specific populations may help to elucidate
its implications for human health. [Hernandez-Elizondo, J.;

 Vaccination Knowledge and Beliefs JOURNAL OF COMMUNITY HEALTH
 English Article HPV
 (Human papillomavirus); Arabs; Vaccinations; Prevention;
 Immigration AGED 13-17 YEARS; UNITED-STATES; CERVICAL-CANCER;
 HEALTH-CARE; MIDDLE-EAST; ADOLESCENTS; INFECTION; AWARENESS;
 COVERAGE; WOMEN Little is known of Arab Americans' human
 papilloma virus vaccination (HPV) behaviors. We explored
 associations between US Arab immigrant mothers' beliefs regarding
 HPV for their children with socioeconomic, medical, and
 religious/cultural factors. A cross-sectional survey was conducted
 in New York City (August 2019-April 2021) with 162 Arab American
 immigrant women who had at least one child aged 9 through 26
 years. Among those reporting that their child/children had not
 received the HPV (63.5%), reasons included not having heard of it
 (67.3%) and lack of provider recommendation (59.4%). HPV
 awareness and uptake, respectively, were more likely among those
 with education ≥ 10 years ($p < .001$ and $p < .001$, respectively),
 with more years in the US ($p < .001$ and $p < .001$), and with higher
 household income ($p < .001$ and $p = .002$). Participants with
 limited English proficiency were less likely to have HPV
 awareness and uptake ($p < .001$ and $p < .001$). Christian religious
 affiliation was positively associated with HPV awareness and
 uptake ($p = .014$ and $p = .048$). A greater number of years in the
 US was significantly associated with willingness to vaccinate if
 recommended by the doctor ($p = .031$). In open-ended responses,
 mothers indicated that they did not receive strong provider HPV
 recommendations, potentially because of their providers'
 perceptions of their cultural backgrounds. Mothers indicated a
 desire for HPV educational materials in Arabic to help them with
 decision making. Potential opportunities to augment HPV uptake
 among Arab immigrants' children include increasing population
 knowledge, increasing provider recommendation, and providing
 culturally/religiously responsive HPV education in English and
 Arabic. [Ayash, Claudia; Raad, Noor; Finik, Jackie; Attia,

J Anderson, JG; Taylor, AG Anderson, Joel
G.; Taylor, Ann Gill Use of Complementary Therapies
for Cancer Symptom Management: Results of the 2007 National Health
Interview Survey JOURNAL OF ALTERNATIVE AND COMPLEMENTARY MEDICINE
English Article

ALTERNATIVE MEDICINE; MEDITERRANEAN DIET; BREAST-
CANCER; INTERVENTIONS Objectives: Complementary therapies are
often used as adjuncts to conventional treatment by individuals
with cancer. Patterns of use of these practices and products
represent important data for health care providers in delivering
adequate patient care. Design: This study compared use of
complementary therapies between the cancer and noncancer
populations in the United States through secondary analyses of the
2007 National Health Interview Survey data. The analysis compared
use by cancer survivors (those individuals self-reporting a
diagnosis of cancer; n = 1785) and individuals without cancer (n =
21,585), as well as self-report of symptoms affecting health-
related quality of life (HQoL). Results: Data suggest similar
patterns of use between cancer survivors and the general
population; however, a greater percentage of cancer survivors use
complementary modalities. Individuals with cancer reported a
greater percentage of use of complementary therapies overall, with
cancer status significantly associated with ever having used
complementary and alternative medicine (p < 0.001). The five most
common complementary practices and products used by individuals
with cancer and controls were vitamin/mineral supplements, prayer
for self, intercessory prayer, chiropractic/osteopathic
manipulation, and herbal therapies. Additionally, as might be
expected, individuals with cancer experience greater frequency of
deleterious symptoms associated with decreased HQoL. Individuals
with cancer were more likely to sleep fewer than 7 hours (p =
0.0108) or greater than 9 hours (p = 0.0108), and have increased

insomnia ($p < 0.001$), excessive sleepiness ($p < 0.001$), depression ($p < 0.001$), and anxiety ($p < 0.001$) versus those without cancer. Conclusions: The current findings may inform health care providers about the use of complementary and integrative practices and products by patients with cancer in an effort to manage symptoms of the disease. Additionally, these results may also be used to promote research to define the merits of the use of such complementary and integrative practices and products.

J Malcomson, FC; Mathers, JC Malcomson, F.
C.; Mathers, J. C. Translation of nutrigenomic

research for personalised and precision nutrition for cancer
prevention and for cancer survivors REDOX BIOLOGY

English Article

Nutrigenomics; Personalised nutrition; Cancer prevention
HEREDITARY COLORECTAL-CANCER; BREAST-CANCER; INTERINDIVIDUAL
VARIATION; MEDITERRANEAN DIET; DNA METHYLATION; PROSTATE-CANCER;
EXCISION-REPAIR; GUT MICROBIOTA; RED MEAT; RISK Personalised
and precision nutrition uses information on individual
characteristics and responses to nutrients, foods and dietary
patterns to develop targeted nutritional advice that is more
effective in improving the diet and health of each individual.
Moving away from the conventional 'one size fits all', such
targeted intervention approaches may pave the way to better
population health, including lower burden of non-communicable
diseases. To date, most personalised and precision nutrition
approaches have been focussed on tackling obesity and
cardiometabolic diseases with limited efforts directed to cancer
prevention and for cancer survivors. Advances in understanding the

biological basis of cancer and of the role played by diet in cancer prevention and in survival after cancer diagnosis, mean that it is timely to test and to apply such personalised and precision nutrition approaches in the cancer area. This endeavour can take advantage of the enhanced understanding of interactions between dietary factors, individual genotype and the gut microbiome that impact on risk of, and survival after, cancer diagnosis. Translation of these basic research into public health action should include realtime acquisition of nutrigenomic and related data and use of AI-based data integration methods in systems approaches that can be scaled up using mobile devices.

human epidermal growth factor receptor 2 (HER2) is associated with
hyperglycaemia and insulin resistance JOURNAL OF DIABETES

English Article

epidermal growth factor receptor; ethnicity; human epidermal
growth factor receptor 2 (HER2); insulin sensitivity; type 2
diabetes mellitus DIABETES-MELLITUS; BREAST-CANCER; BLADDER-
CANCER; METABOLIC SYNDROME; PROSTATE-CANCER; MIDDLE-EAST; RISK;
IMMIGRANTS; METFORMIN; SURVIVAL BackgroundType 2 diabetes
mellitus (T2DM) and human epidermal growth factor receptor 2
(HER2) are associated with cancer, although the role of HER2 in
T2DM is not well defined. The aim of this study was to investigate
the association between HER2 levels and T2DM and whether that
association differed in Swedish people born in Iraq or Sweden.
MethodsCirculating HER2 levels were analyzed by the Luminex assay
in 95 Iraqi-born and 75 Swedish-born Swedes. ResultsThere were
significant differences in HER2 among those with normal glucose
tolerance (NGT), impaired fasting glucose (IFG) and/or impaired
glucose tolerance (IGT), and T2DM in the entire population after

adjusting for age, sex, and body mass index (BMI; $P=0.03$). Stratification of data according to country of birth revealed significant differences in HER2 levels among NGT, IFG/IGT, and T2DM groups only in Swedes ($P=0.007$). For the entire study population, there was a positive association between HER2 and hyperglycemia (IFG and/or IGT+T2DM; $P=0.011$), BMI, waist circumference, serum insulin, homeostatic model assessment of β -cell function, HbA1c, triglycerides, and C-peptide ($P < 0.05$), and a negative association between HER2 and insulin sensitivity index (ISI; $P < 0.0001$). Bivariate and multivariate linear regression analyses on the whole study population revealed that the associations between hyperglycemia and HER2, as well as between ISI and HER2, were independent of factors known to be associated with T2DM and insulin resistance (e.g. demographics, obesity, lipids, sedentary lifestyle, a family history of T2DM, C-peptide, and C-reactive protein). Conclusions There is an independent association between HER2 levels and hyperglycemia and insulin resistance that is not modified by country of birth. Pooled analysis of fluorouracil-based adjuvant therapy for stage II and III colon cancer:: Who benefits and by how much? JOURNAL OF CLINICAL ONCOLOGY English

Article; Proceedings Paper 39th Annual Meeting of the

American-Society-of-Clinical-Oncology (ASCO) MAY 31-JUN 03, 2003
Chicago, IL Amer Soc Clin Oncol (ASCO) TUMOR
MICROSATELLITE-INSTABILITY; NSABP CLINICAL-TRIALS; PRIMARY BREAST-
CANCER; COLORECTAL-CANCER; FOLINIC ACID; DUKES-B; PROGNOSTIC-
SIGNIFICANCE; SYSTEMIC THERAPY; CHEMOTHERAPY; SURVIVAL Purpose
Although it is well-established that fluorouracil- (FU-) based
adjuvant therapy improves survival for patients with resected
high-risk colon cancer, the magnitude of adjuvant therapy benefit
across specific subgroups and for individual patients has been
uncertain. Patients and Methods Using a pooled data set of 3,302
patients with stage II and III colon cancer from seven randomized
trials comparing FU + leucovorin or FU + levamisole to surgery
alone, we performed an analysis based on a Cox proportional
hazards regression model. Treatment, age, sex, tumor location, T
stage, nodal status, and grade were tested for both prognostic and
predictive significance. Model derived estimates of 5-year
disease-free survival and overall survival (OS) for surgery alone
and surgery plus FU-based therapy were calculated for a range of
patient subsets. Results Nodal status, T stage, and grade were the
only prognostic factors independently significant for both
disease-free survival and OS. Age was significant only for OS. In
a multivariate analysis, adjuvant therapy showed a beneficial
treatment effect across all subsets. Treatment benefits were
consistent across sex, location, age, T-stage, and grade. A
significant stage by treatment interaction was present, with
treatment benefiting stage III patients to a greater degree than
stage II patients. Conclusion Patients with high-risk resected
colon cancer obtain benefit from FU-based therapy across subsets
of age, sex, location, T stage, nodal status, and grade. Model
estimates of survival stratified by T stage, nodal status, grade,
and age are available at <http://www.mayoclinic.com/calcs>. This
information may improve patients' and physicians' understanding of
the potential benefits of adjuvant therapy. (C) 2004 by American

 JUL 02, 2015 Athens, GREECE Metabolomics;
 Metabolic profiling; Feces; Extraction optimization; Sample
 preparation INFLAMMATORY-BOWEL-DISEASE; GUT MICROBIOTA;
 COLORECTAL-CANCER; HUMAN FECES; EXTRACTS; SPECTROMETRY; WATER;
 DERIVATIZATION; PATHOGENESIS; GENETICS Metabolomic analysis of
 feces can provide useful insight on the metabolic status, the
 health/disease state of the human/animal and the symbiosis with
 the gut microbiome. As a result, recently there is increased
 interest on the application of holistic analysis of feces for
 biomarker discovery. For metabolomics applications, the sample
 preparation process used prior to the analysis of fecal samples is
 of high importance, as it greatly affects the obtained metabolic
 profile, especially since feces, as matrix are diversifying in
 their physicochemical characteristics and molecular content.
 However there is still little information in the literature and
 lack of a universal approach on sample treatment for fecal
 metabolic profiling. The scope of the present work was to study
 the conditions for sample preparation of rat feces with the
 ultimate goal of the acquisition of comprehensive metabolic
 profiles either untargeted by NMR spectroscopy and GC MS or
 targeted by HILIC-MS/MS. A fecal sample pooled from male and
 female Wistar rats was extracted under various conditions by
 modifying the pH value, the nature of the organic solvent and the
 sample weight to solvent volume ratio. It was found that the 1/2
 (wt./vs) ratio provided the highest number of metabolites under
 neutral and basic conditions in both untargeted profiling
 techniques. Concerning LC MS profiles, neutral acetonitrile and
 propanol provided higher signals and wide metabolite coverage,
 though extraction efficiency is metabolite dependent. (C) 2016

Walnuts Have Potential for Cancer Prevention and Treatment
in Mice JOURNAL OF NUTRITION English Article;
Proceedings Paper Symposium on What Comes First - The Food or
the Nutrient as a Satellite Session to the American-Society-for-
Nutrition Scientific Sessions and Annual Meeting at Experimental
Biology APR 19, 2013 Boston, MA Amer Soc Nutr

MAMMARY-GLAND TUMORIGENESIS; ACID-DERIVED METABOLITES; BETA-
SITOSTEROL; BREAST-CANCER; ELLAGIC ACID; MEDITERRANEAN DIET; NUDE-
MICE; COLORECTAL-CANCER; GAMMA-TOCOPHEROL; GUT MICROBIOTA

Cancer may not be completely the result of novel or
inherited genetic mutations but may in fact be a largely
preventable disease. Researchers have identified biochemicals,
including n-3 (omega-3) fatty acids, tocopherols, beta-sitosterol,
and pedunculagin, that are found in walnuts and that have cancer-
prevention properties. Mouse studies in which walnuts were added
to the diet have shown the following compared with the control
diet: 1) the walnut-containing diet inhibited the growth rate of
human breast cancers implanted in nude mice by similar to 80%; 2)
the walnut-containing diet reduced the number of mammary gland
tumors by similar to 60% in a transgenic mouse model; 3) the
reduction in mammary gland tumors was greater with whole walnuts
than with a diet containing the same amount of n-3 fatty acids,
supporting the idea that multiple components in walnuts additively
or synergistically contribute to cancer suppression; and 4)
walnuts slowed the growth of prostate, colon, and renal cancers by
antiproliferative and antiangiogenic mechanisms. Cell studies have
aided in the identification of the active components in walnuts
and of their mechanisms of action. This review summarizes these
studies and presents the notion that walnuts may be included as a
cancer-preventive choice in a healthy diet. Marshall Univ, Sch

Survival following recurrence in
stage II and III colon cancer:: Findings from the ACCENT data set

JOURNAL OF CLINICAL ONCOLOGY

English Article

METASTATIC COLORECTAL-

CANCER; PHASE-III; FLUOROURACIL; LEUCOVORIN; PLUS; IRINOTECAN;

RESECTION Purpose This study was undertaken to examine five
possible prognostic factors in patients with recurrent stage II
and III colon cancer: time from randomization on an adjuvant
therapy clinical trial to tumor recurrence (< 1 year, 1 to 2
years, 2 to 3 years, 3 to 4 years, > 4 years), initial stage (II v
III), initial adjuvant treatment (fluorouracil [FU]-based v
surgery alone), the era in which the patient entered an adjuvant
therapy clinical trial (1978 to 1985, 1986 to 1992, 1993 to 1999),
and patient age at recurrence. Methods The Adjuvant Colon Cancer
End Points (ACCENT) data set was analyzed using univariate and
multivariate Cox proportional hazards models, stratified by study.
Results 5,722 (32.9%) of 17,381 patients experienced recurrence.
Median survival following recurrence was 13.3 months. Time from
randomization to recurrence was highly prognostic of survival
following recurrence ($P < .0001$). Longer survival following
recurrence was seen in patients with initial stage II versus III
disease ($P < .0001$; 14.3% 6-year overall survival after recurrence
in initial stage II patients), patients entered more recently onto
trials ($P < .0001$), and patients initially treated with surgery
alone versus FU adjuvant treatment ($P = .0005$). All relationships
were maintained in multivariate models. Conclusion Time from
initial treatment to recurrence and initial stage are important
prognostic factors in patients with recurrent colon cancer.
Survival following recurrence increased modestly from 1978 to
1999. Patients who had a recurrence following adjuvant therapy had
poorer prognosis than those who progressed after surgery alone.
These prognostic factors may be useful for clinical trial design
and treatment decisions in patients with recurrent colon cancer.

A dietary pattern promoting gut sulfur metabolism is associated with increased mortality and altered circulating metabolites in low-income American adults EBIOMEDICINE

English Article

Dietary patterns; Gut

microbiota; Metabolomics; Prospective studies; Racial minorities; Low-income population FOOD FREQUENCY QUESTIONNAIRE; MICROBIAL DIET; MEDITERRANEAN DIET; COLORECTAL-CANCER; INCREASED RISK; DISEASE; COHORT Background Excessive hydrogen sulfide in the gut, generated by sulfur-metabolising bacteria from foods, has been linked to intestinal inflammation and human diseases. We aim to investigate the interplay between diet and sulphur-metabolising bacteria in relation to mortality and circulating metabolites in understudied populations. Methods In the Southern Community Cohort Study (SCCS), a prospective cohort of primarily low-income American adults, habitual diets were assessed using a food frequency questionnaire at baseline (2002-2009). A sulfur microbial diet score (SMDS) was developed among 514 Black/African American participants by linking habitual dietary intakes with the abundance of sulfur-metabolising bacteria profiled by faecal shotgun metagenomics. The SMDS was then constructed among all eligible SCCS participants (50,114 Black/African American and 23,923 non-Hispanic White adults), and its associations with mortality outcomes were examined by Cox proportional hazards model and Fine-Grey subdistribution hazard model. The association between SMDS and 1110 circulating metabolites was examined by linear regression among 1688 SCCS participants with untargeted metabolomic profiling of baseline plasma samples. Findings Over an average 13.9-year follow-up, SMDS was associated with increased all-cause mortality (HR [95% CI] for the highest vs. lowest quartiles: 1.21 [1.15-1.27]) and cardiovascular disease (1.18 [1.08-1.29]), cancer (1.13 [1.02-1.25]), and gastrointestinal cancer-specific (1.22 [1.00-1.49]) mortality among Black/African American participants (all P-trend<0.05). The associations were largely consistent across participant subgroups. Similar results

were observed among non-Hispanic White participants. The SMDS was associated with 112 circulating metabolites, which mediated 36.15% of the SMDS-mortality association ($P = 0.002$). Interpretation A dietary pattern promoting sulfur-metabolising gut bacteria may contribute to increased total and disease mortality in low-income American adults. Nut intake and 5-year changes in body weight and obesity
risk in adults: results from the EPIC-PANACEA study EUROPEAN
JOURNAL OF NUTRITION English Article

Nut intake; Weight gain; Obesity; Energy
balance; Adults; Europe MEDITERRANEAN DIET; COLORECTAL-CANCER;
PHYSICAL-ACTIVITY; CONSUMPTION; DISEASE; HEALTH; GAIN;
PARTICIPANTS; ASSOCIATION; VALIDITY There is inconsistent
evidence regarding the relationship between higher intake of nuts,
being an energy-dense food, and weight gain. We investigated the
relationship between nut intake and changes in weight over 5
years. This study includes 373,293 men and women, 25-70 years old,
recruited between 1992 and 2000 from 10 European countries in the
European Prospective Investigation into Cancer and Nutrition
(EPIC) study. Habitual intake of nuts including peanuts, together
defined as nut intake, was estimated from country-specific
validated dietary questionnaires. Body weight was measured at
recruitment and self-reported 5 years later. The association
between nut intake and body weight change was estimated using
multilevel mixed linear regression models with center/country as
random effect and nut intake and relevant confounders as fixed
effects. The relative risk (RR) of becoming overweight or obese
after 5 years was investigated using multivariate Poisson
regressions stratified according to baseline body mass index
(BMI). On average, study participants gained 2.1 kg (SD 5.0 kg)
over 5 years. Compared to non-consumers, subjects in the highest
quartile of nut intake had less weight gain over 5 years (-0.07
kg; 95% CI -0.12 to -0.02) (P trend = 0.025) and had 5% lower risk
of becoming overweight (RR 0.95; 95% CI 0.92-0.98) or obese (RR
0.95; 95% CI 0.90-0.99) (both P trend < 0.008). Higher intake of
nuts is associated with reduced weight gain and a lower risk of
becoming overweight or obese. [Freisling, Heinz; Noh,

Mauro, Nicolo; Scialabba, Cinzia; Pitarresi, Giovanna;
Giammona, Gaetano Enhanced adhesion and in situ
photothermal ablation of cancer cells in surface-functionalized
electrospun microfiber scaffold with graphene oxide

INTERNATIONAL JOURNAL OF PHARMACEUTICS English

Article Cell capture; Hybrid

materials; Plasma; Polycaprolactone; Graphene oxide; Cancer
therapy METASTATIC BREAST-CANCER; CIRCULATING TUMOR-CELLS;
THERAPY; PLASMA; SUBSTRATE; BEHAVIOR; GROWTH The physicochemical
characteristics of a biomaterial surface highly affect the
interaction with living cells. Recently, much attention has been
focused on the adhesion properties of functional biomaterials
toward cancer cells, since is expected to control metastatic
spread of a tumor, which is related to good probability containing
the progression of disease burden. Here, we designed an
implantable poly(caprolactone)based electrospun microfiber
scaffold, henceforth PCLMF-GO, to simultaneously capture and kill
cancer cells by tuning physicochemical features of the hybrid
surface through nitrogen plasma activation and hetero-phase
graphene oxide (GO) covalent functionalization. The surface
immobilization of GO implies enhanced cell adhesion and
proliferation, promoting the selective adhesion of cancer cells,
even if allowing cancer associated fibroblast (CAFs) capture. We
also display that the functionalization with GO, thanks to the
high near-infrared (NIR) absorbance, enables the discrete
photothermal eradication of the captured cancer cells in situ
(approximate to 98%). (C) 2017 Elsevier B.V. All rights reserved.

(-)-Oleocanthal and (-)-oleocanthal-rich olive
oils induce lysosomal membrane permeabilization in cancer cells
PLOS ONE English Article
CYSTEINE CATHEPSINS; BREAST-CANCER;
MEDITERRANEAN DIET; MOUSE MODEL; OLEOCANTHAL; EXPRESSION; TRIAL;
RISK (-)-Oleocanthal (oleocanthal) is a phenolic compound found
in varying concentrations in extra virgin olive oil oleocanthal
has been shown to be active physiologically, benefiting several
diseased states by conferring anti-inflammatory and
neuroprotective benefits. Recently, we and other groups have
demonstrated its specific and selective toxicity toward cancer
cells; however, the mechanism leading to cancer cell death is
still disputed. The current study demonstrates that oleocanthal,
as well as naturally oleocanthal-rich extra virgin olive oils,
induced damage to cancer cells' lysosomes leading to cellular
toxicity in vitro and in vivo. Lysosomal membrane permeabilization
following oleocanthal treatment in various cell lines was assayed
via three complementary methods. Additionally, we found
oleocanthal treatment reduced tumor burden and extended lifespan
of mice engineered to develop pancreatic neuroendocrine tumors.
Finally, following-up on numerous correlative studies
demonstrating consumption of olive oil reduces cancer incidence
and morbidity, we observed that extra virgin olive oils naturally
rich in oleocanthal sharply reduced cancer cell viability and
induced lysosomal membrane permeabilization while oleocanthal-poor
oils did not. Our results are especially encouraging since tumor
cells often have larger and more numerous lysosomes, making them
especially vulnerable to lysosomotropic agents such as
oleocanthal. [Goren, Limor; Foster, David A.] CUNY, Dept Biol

Borzacchiello, Giuseppe Molecular and epigenetic
analysis of the fragile histidine triad tumour suppressor gene in
equine sarcoids BMC VETERINARY RESEARCH English

Article

FACTOR-BETA

RECEPTOR; BOVINE PAPILLOMAVIRUS E5; FHIT GENE; ONCOPROTEIN BINDS;
URINARY-BLADDER; CERVICAL-CANCER; GROWTH; METHYLATION; EXPRESSION;
PROMOTER Background: Sarcoids are peculiar equine benign
tumours. Their onset is associated with Bovine Papillomavirus type
-1 or -2 (BPV-1/2) infection. Little is known about the molecular
interplay between viral infection and neoplastic transformation.
The data regarding papillomavirus infections in human species show
the inactivation of a number of tumour suppressor genes as basic
mechanism of transformation. In this study the putative role of
the tumour suppressor gene Fragile Histidine Triad (FHIT) in
sarcoid tumour was investigated in different experimental models.
The expression of the oncosuppressor protein was assessed in
normal and sarcoid cells and tissue. Results: Nine paraffin
embedded sarcoids and sarcoid derived cell lines were analysed for
the expression of FHIT protein by immunohistochemistry,
immunofluorescence techniques and western blotting. These analyses
revealed the absence of signal in seven out of nine sarcoids. The
two sarcoid derived cell lines too showed a reduced signal of the
protein. To investigate the causes of the altered protein
expression, the samples were analysed for the DNA methylation
profile of the CpG island associated with the FHIT promoter. The
analysis of the 32 CpGs encompassing the region of interest showed

no significative differential methylation profile between pathological tissues and cell lines and their normal counterparts. Conclusion: This study represent a further evidence of the role of a tumour suppressor gene in equine sarcoids and approaches the epigenetic regulation in this well known equine neoplasm. The data obtained in sarcoid tissues and sarcoid derived cell lines suggest that also in horse, as in humans, there is a possible involvement of the tumour suppressor FHIT gene in BPV induced tumours. DNA methylation seems not to be involved in the gene expression alteration. Further studies are needed to understand the basic molecular mechanisms involved in reduced FHIT expression.

Coping strategies and perceived social support among cancer patients: A cross-sectional analysis MEDITERRANEAN JOURNAL OF CLINICAL PSYCHOLOGY English Article

Coping; Social support; Cancer; Psycho-oncology; Adjustment QUALITY-OF-LIFE; MENTAL ADJUSTMENT; BREAST-CANCER; MULTIDIMENSIONAL SCALE; MINI-MAC; WOMEN Background: Cancer is a major public health problem worldwide. Being the

second leading cause of death in the world, this fearsome disease is a stressful event capable to cause a time of considerable upheaval in people's lives and their loved ones. The illness condition can influence the patients' social relationships, even reducing social involvement and fostering isolation. Hence, cancer adjustment-related variables are worth studying. Specifically, the research on coping strategies is crucial since the patients' response style can act on the quality of the psychosocial outcomes. Objective: The aim of this study was deepening the association between coping styles and perceived social support from family, friends, and significant others among a sample of 121 cancer patients. Method: Participants were 121 cancer patients (70.2% females), aged 26 to 88 (M=61.90, SD=12.16). We assessed the adopted coping strategies by means of the Mini-Mental Adjustment to Cancer Scale (mini-MAC Scale), whereas the perceived social support was measured by the Multidimensional Scale of Perceived Social Support (MSPSS). Results: We found: (1) a positive association between fighting spirit and the perception of social support from friends; (2) the hopelessness/helplessness strategy seemed negatively related with the perception of social support, regardless of the source; (3) higher levels of fatalism were connected with higher levels of perceived social support from family; (4) both anxious preoccupation and avoidance did not show any association with perceived social support. Conclusions: Working on maladaptive coping responses might be useful for the purpose of improving the receptivity to the support from family, friends and significant others. Further research focusing on patients' coping styles is needed to promote holistic-oriented psychological treatments. Petrarca, C; Rughetti, A; Rahimi, H; DAgostini, F; Turchi, V; Ghetti, CA; Scambia, G; Frati, L; Nuti, M Human antibodies against the polymorphic epithelial mucin in ovarian cancer patients recognise a novel sequence in the tandem repeat region EUROPEAN JOURNAL OF CANCER English

Article polymorphic epithelial mucin; immune response; human antibodies; epitope mapping; tumour-associated antigens MONOCLONAL-ANTIBODIES; BREAST-CANCER; CORE-PROTEIN; CARCINOMA PATIENTS; T-CELLS; EPITOPE; IMMUNITY; ANTIGEN; EXPRESSION; MILK The humoral immune response to the polymorphic epithelial mucin (PEM) was studied by characterising the reactivity of human antibodies generated by EBV-immortalised B-cells from tumour-draining lymph nodes of

ovarian cancer patients. All the human antibodies, selected in ELISA for their reactivity to the protein core tandem repeat sequence, reacted with PEM-expressing tumour cells. Aberrant glycosylation of the peptide core of the PEM molecule in cancer cells leads to the exposure of peptide epitopes that can be considered tumour specific. The epitope mapping of six human antibodies revealed that only one of them contained the PDTR sequence, shown to be the immunodominant epitope in the mouse. Four of the six human antibodies recognised a novel common immunogenic sequence (APPAH) in the tandem repeats. The binding of these human antibodies did not appear to be modulated by the length of the carbohydrate side chains, as shown by O-glycosylation inhibition studies. These results indicate that distinct sequences within the tandem repeat of PEM are target for a humoral immune response in humans. The presence of antibodies directed against different epitopes within the same antigenic region may modulate the antigen presentation process and the ongoing immune response. These data may help in clarifying the mechanisms of the immune response to PEM in cancer patients for the development of PPM-based immunotherapy. Daiki; Hebert, James R.; Koike, Tatsuya Change in
dietary inflammatory index score is associated with control of
long-term rheumatoid arthritis disease activity in a Japanese
cohort: the TOMORROW study ARTHRITIS RESEARCH & THERAPY
English Article

Inflammation; Nutrition; Diet; Lifestyle; Rheumatoid
arthritis COLORECTAL-CANCER RISK; HISTORY QUESTIONNAIRES;
MEDITERRANEAN DIET; FATTY-ACIDS; HEALTH; INTERVENTION; VALIDATION;
MORTALITY; CRITERIA; OLDER Background: The dietary inflammatory
index (DII (R)), a quantitative measure of the inflammatory
potential of daily food and nutrient intake, and associations
between a variety of health outcomes have been reported. However,
the association between DII score and disease activity of
rheumatoid arthritis (RA) is unclear. Therefore, this study was
designed to test whether higher DII score contributes to disease
activity and as a corollary, whether reducing DII score helps to

achieve or maintain low disease activity or remission in patients with RA. Methods: We performed a cross-sectional and longitudinal analysis using 6 years of data (from 2011 to 2017) in TOMORROW, a cohort study consisting of 208 RA patients and 205 gender- and age-matched controls started in 2010. Disease activity of RA patients was assessed annually using DAS28-ESR (disease activity score 28 joints and the erythrocyte sedimentation rate) as a composite measure based on arthritic symptoms in 28 joints plus global health assessment and ESR. Dietary data were collected in 2011 and 2017 using the brief-type self-administered diet history questionnaire (BDHQ). Energy-adjusted DII (E-DII (TM)) score was calculated using 26 nutrients derived from the BDHQ. Data were analyzed with two-group comparisons, correlation analysis, and multivariable logistic regression analysis. Results: One hundred and seventy-seven RA patients and 183 controls, for whom clinical and dietary survey data were available, were analyzed. RA patients had significantly higher E-DII (pro-inflammatory) score compared to controls both in 2011 and 2017 ($p < 0.05$). In RA patients, E-DII score was not a factor associated with significant change in disease activity. However, anti-inflammatory change in E-DII score was associated maintaining low disease activity (DAS28-ESR ≤ 3.2) or less for 6 years (OR 3.46, 95% CI 0.33-8.98, $p = 0.011$). Conclusions: The diets of RA patients had a higher inflammatory potential than controls. Although E-DII score was not a factor associated with significant disease activity change, anti-inflammatory change in E-DII score appeared to be associated with maintaining low disease activity in patients with RA.

CELL LUNG-CANCER; CLONAL EVOLUTION; TARGETED THERAPY; TUMOR HETEROGENEITY; ACQUIRED-RESISTANCE; EGFR BLOCKADE; COPY NUMBER; COMPETITION; INHIBITORS; MUTATIONS Drug resistance mediated by clonal evolution is arguably the biggest problem in cancer therapy today. However, evolving resistance to one drug may come at a cost of decreased fecundity or increased sensitivity to another drug. These evolutionary trade-offs can be exploited using 'evolutionary steering' to control the tumour population and delay resistance. However, recapitulating cancer evolutionary dynamics experimentally remains challenging. Here, we present an approach for evolutionary steering based on a combination of single-cell barcoding, large populations of 10(8)-10(9) cells grown without re-plating, longitudinal non-destructive monitoring of cancer clones, and mathematical modelling of tumour evolution. We demonstrate evolutionary steering in a lung cancer model, showing that it shifts the clonal composition of the tumour in our favour, leading to collateral sensitivity and proliferative costs. Genomic profiling revealed some of the mechanisms that drive evolved sensitivity. This approach allows modelling evolutionary steering strategies that can potentially control treatment resistance. Evolutionary steering uses therapies to control tumour evolution by exploiting trade-offs. Here, using a barcoding approach applied to large cell populations, the authors explore evolutionary steering in lung cancer cells treated with EGFR inhibitors.  Chemical characterization and cytotoxic activity
 evaluation of Lebanese propolis BIOMEDICINE & PHARMACOTHERAPY
 English Article

Lebanese propolis; Apoptosis; Cytotoxicity; Plant extract
 ACID PHENETHYL ESTER; HUMAN OSTEOSARCOMA CELLS; BRAZILIAN
 RED PROPOLIS; HUMAN BREAST-CANCER; IN-VITRO EVALUATION;
 BIOLOGICAL-ACTIVITIES; ANTITUMOR-ACTIVITY; INDUCED APOPTOSIS;
 ETHANOL EXTRACTS; ANTICANCER DRUGS Chemical composition,
 anti-proliferative and proapoptotic activity as well as the effect
 of various fractions of Lebanese propolis on the cell cycle
 distribution were evaluated on Jurkat leukemic T-cells,
 glioblastoma U251 cells, and breast adenocarcinoma MDA-MB-231

cells using cytotoxic assays, flow cytometry as well as western blot analysis. Liquid chromatography-tandem mass spectrometry (LC-MS/MS) analysis revealed that ferulic acid, chrysin, pinocembrin, galangin are major constituents of the ethanolic crude extract of the Lebanese propolis, while the hexane fraction mostly contains chrysin, pinocembrin, galangin but at similar levels. Furthermore chemical analysis was performed using gas chromatography-mass spectrometry (GC-MS) to identify major compounds in the hexane fraction. Reduction of cell viability was observed in Jurkat cells exposed to the ethanolic crude extract and the hexane fraction, while viability of U251 and MDA-MB-231 cells was only affected upon exposure to the hexane fraction; the other fractions (aqueous phase, methylene chloride, and ethyl acetate) were without effect. Maximum toxic effect was obtained when Jurkat cells were cultivated with 90 μ g/ml of both the crude extract and hexane fraction. Toxicity started early after 24 h of incubation and remained till 72 h. Interestingly, the decrease in cell viability was accompanied by a significant increase in p53 protein expression levels and PARP cleavage. Cell cycle distribution showed an increase in the SubG0 fraction in Jurkat, U251 and MDA-MB-231 cells after 24 h incubation with the hexane fraction. This increase in SubG0 was further investigated in Jurkat cells by annexinV/PI and showed an increase in the percentage of cells in early and late apoptosis as well as necrosis. In conclusion, Lebanese propolis exhibited significant cytotoxicity and anti-proliferative activity promising enough that warrant further investigations on the molecular targets and mechanisms of action of Lebanese propolis. Investigation on metabolism of cisplatin resistant ovarian cancer using a genome scale metabolic model and microarray data IRANIAN JOURNAL OF BASIC MEDICAL SCIENCES

English Article

Cisplatin

resistance; Drug target; Lactate; Metabolism; Microarray; Warburg effect RAT-LIVER MITOCHONDRIA; GLOBAL RECONSTRUCTION;

EXPRESSION DATA; BREAST-CANCER; NETWORK; PREDICTION; GROWTH;

PROLIFERATION; INTEGRATION; TARGETS Objective(s): Many cancer

cells show significant resistance to drugs that kill drug sensitive cancer cells and non-tumor cells and such resistance

might be a consequence of the difference in metabolism. Therefore, studying the metabolism of drug resistant cancer cells and

comparison with drug sensitive and normal cell lines is the

objective of this research. Material and Methods: Metabolism of cisplatin resistant and sensitive A2780 epithelial ovarian cancer cells and normal ovarian epithelium has been studied using a

generic human genome-scale metabolic model and transcription data.

Result: The results demonstrate that the most different

metabolisms belong to resistant and normal models, and the

different reactions are involved in various metabolic pathways.

However, large portion of distinct reactions are related to

extracellular transport for three cell lines. Capability of metabolic models to secrete lactate was investigated to find the

origin of Warburg effect. Computational results introduced

SLC25A10 gene, which encodes mitochondrial dicarboxylate

transporter involved in exchanging of small metabolites across the mitochondrial membrane that may play key role in high growing

capacity of sensitive and resistant cancer cells. The metabolic

models were also used to find single and combinatorial targets

that reduce the cancer cells growth. Effect of proposed target

genes on growth and oxidative phosphorylation of normal cells were determined to estimate drug side-effects. Conclusion: The deletion

results showed that although the cisplatin did not cause resistant cancer cells death, but it shifts the cancer cells to a more

vulnerable metabolism. [Motamedian, Ehsan] Tarbiat Modares Univ,

 J Cai, H; Shu, XO; Gao, YT; Li, HL; Yang, G; Zheng, W
 Cai, Hui; Shu, Xiao Ou; Gao, Yu-Tang; Li,
 Honglan; Yang, Gong; Zheng, Wei A prospective study
 of dietary patterns and mortality in Chinese women EPIDEMIOLOGY
 English Article
 BODY-MASS INDEX; MEDITERRANEAN DIET; ELDERLY-PEOPLE;
 COLORECTAL-CANCER; CLUSTER-ANALYSIS; EATING PATTERNS; COHORT;
 RISK; ADULTS; SURVIVAL Background: Many foods and nutrients have
 been suggested to influence life expectancy. However, previous
 studies have not examined the relationship between dietary
 patterns and cause-specific mortality. Our study prospectively
 examines the relationship of dietary patterns with total mortality
 and cause-specific mortality in a population-based cohort study of
 Chinese women. Methods: The Shanghai Women's Health Study is a
 population-based cohort study of 74,942 women age 40 to 70 years
 at the time of recruitment (September 1996 to May 2000). Detailed
 dietary information was collected using a validated, quantitative
 food frequency questionnaire. The cohort has been followed using a
 combination of in-person interviews and record linkage with
 various registries. Dietary patterns, derived from principal
 component analysis, were examined for their relation to total
 mortality and cause-specific mortality using Cox regression
 models. Results: After an average of 5.7 years of follow-up
 (423,717 person-years of observation), there were 1565 deaths. We
 derived 3 major dietary patterns (vegetable-rich, fruit-rich, and
 meat-rich). The adjusted hazard ratios for the fruit-rich diet
 were 0.94 (95% CI = 0.89-0.98) for all causes of death and 0.89
 (0.81-0.99), 0.79 (0.69-0.91), and 0.51 (0.39-0.65) for death
 caused by cardiovascular disease, stroke, and diabetes,
 respectively. The meat-rich diet was associated with increased
 risk of diabetes (HR = 1.18; 95% CI = 0.98-1.42) and a slightly
 elevated risk of total mortality. Conclusion: In general, a fruit-
 rich diet was related to lower mortality, whereas a meat-rich diet
 appeared to increase the probability of death. Vanderbilt

Dietary inflammatory index and endometrial cancer risk in an
Italian case-control study BRITISH JOURNAL OF NUTRITION

English Article Dietary
inflammatory index; Diet; Inflammation; Endometrial cancer; Case-
control studies; Italy FOOD-FREQUENCY QUESTIONNAIRE; COLORECTAL-
CANCER; ENDOTHELIAL FUNCTION; CARDIOVASCULAR RISK; MEDITERRANEAN
DIET; GLYCEMIC INDEX; MARKERS; ASSOCIATION; OBESITY;
REPRODUCIBILITY The relation between inflammation deriving from
diet and endometrial cancer risk has not yet been investigated. In
this study, we explored the association between the dietary
inflammatory index (DII) and endometrial cancer risk in an Italian
case-control study. Cases comprised 454 patients with incident,
histologically confirmed carcinoma of the endometrium, and
controls comprised 908 subjects admitted to the same network of
hospitals as cases for a wide spectrum of acute, non-neoplastic
conditions. DII scores were computed on the basis of dietary
intake assessed using a reproducible and valid seventy-eight-item
FFQ. OR were calculated through logistic regression models
conditioned on age and study centre and adjusted for recognised
confounding factors, including total energy intake. Women with the
most pro-inflammatory diet had a higher risk for endometrial
cancer compared with women with the most anti-inflammatory diet (
OR Quartile 4 v. 1 1.46; 95 % CI 1.02, 2.11; P-trend = 0.04). A
pro-inflammatory diet may increase the risk for endometrial
cancer. [Shivappa, Nitin; Hebert, James R.] Univ S Carolina,

Effect of pulsed electric fields - assisted extraction on
anti-inflammatory and cytotoxic activity of brown rice bioactive
compounds FOOD RESEARCH INTERNATIONAL English

Article PEF extraction; Brown
rice; Bioactive compounds; Antioxidant; Cytotoxic activity; HT29
cell line COLON-CANCER CELLS; COLORECTAL-CANCER; ANTIOXIDATIVE
PROPERTIES; GAMMA-ORYZANOL; BY-PRODUCTS; BRAN; RED; POLYPHENOLS;
GROWTH; ANTHOCYANINS The bioactive compounds of brown rice
exhibit many beneficial health effects, ranging from antioxidant
to cytotoxic activities. Pulsed Electric Field (PEF) pretreatment
can significantly enhance their extraction, through the induction
of the electro-permeabilization of the cell membranes. This paper
aims to demonstrate that PEF-assisted extraction of brown rice
enables not only enhanced yields of antioxidant compounds, such as
gamma-oryzanol, polyphenols and phenolic acids, and of saturated
and unsaturated fatty acids, but also increased cytotoxic effects
on cancer cells. Initially, the PEF-assisted extraction conditions
have been defined by the assessment of the cell permeabilization
index via impedance measurements and the DPPH antioxidant
activity. Subsequently, the biological effects of PEF have been
evaluated on the cytotoxicity and anti-inflammatory properties
against human colon cancer cell line HT29. The results show that
PEF-assisted extraction, enhancing the yield of bioactive
compounds, with respect to untreated extracts, significantly
promotes their antioxidant activity, which is correlated with an
increased HT29 cells cytotoxicity. In addition, PEF extracts of
brown rice substantially inhibit also gene expression and
interleukin production in colon cancer cells, suggesting their
exploitation as natural anti-inflammatory agents. The integration
of PEF pretreatment in the solvent extraction process of
bioactives from brown rice appears, therefore, as a promising
practice to significantly enhance their biological activity. (C)

Antiproliferative and Antiangiogenic Effects of Punica
granatum Juice (PGJ) in Multiple Myeloma (MM) NUTRIENTS
English Article

Punica granatum juice; multiple myeloma; proliferation;
angiogenesis PROSTATE-CANCER GROWTH; CELLS IN-VITRO;
POMEGRANATE EXTRACT; BREAST-CANCER; SEED OIL; EXPRESSION;
BORTEZOMIB; ANGIOGENESIS; LINES; PROLIFERATION Multiple
myeloma (MM) is a clonal B-cell malignancy characterized by an
accumulation of clonal plasma cells (PC) in the bone marrow (BM)
leading to bone destruction and BM failure. Despite recent
advances in pharmacological therapy, MM remains a largely
incurable pathology. Therefore, novel effective and less toxic
agents are urgently necessary. In the last few years, pomegranate
has been studied for its potential therapeutic properties
including treatment and prevention of cancer. Pomegranate juice
(PGJ) contains a number of potential active compounds including
organic acids, vitamins, sugars, and phenolic components that are
all responsible of the pro-apoptotic effects observed in tumor
cell line. The aim of present investigation is to assess the
antiproliferative and antiangiogenic potential of the PGJ in human
multiple myeloma cell lines. Our data demonstrate the anti-
proliferative potential of PGJ in MM cells; its ability to induce
G0/G1 cell cycle block and its anti-angiogenic effects.
Interestingly, sequential combination of bortezomib/PGJ improved

the cytotoxic effect of the proteasome inhibitor. We investigated the effect of PGJ on angiogenesis and cell migration/invasion. Interestingly, we observed an inhibitory effect on the tube formation, microvessel outgrowth aortic ring and decreased cell migration and invasion as showed by wound-healing and transwell assays, respectively. Analysis of angiogenic genes expression in endothelial cells confirmed the anti-angiogenic properties of pomegranate. Therefore, PGJ administration could represent a good tool in order to identify novel therapeutic strategies for MM treatment, exploiting its anti-proliferative and anti-angiogenic effects. Finally, the present research supports the evidence that PGJ could play a key role of a future therapeutic approach for treatment of MM in order to optimize the pharmacological effect of bortezomib, especially as adjuvant after treatment. tagged 1; 3-triazoles; Anticancer; Molecular docking study BETA
MESSENGER-RNA; ANTI-HIV ACTIVITY; HEPATOCELLULAR-CARCINOMA;
BREAST-CANCER; POTENTIAL ANTICANCER; CLICK CHEMISTRY; ESTROGEN-
RECEPTORS; NATURAL-PRODUCTS; DERIVATIVES; EXPRESSION 4-((4-(1-
benzyl-2-methyl-4-nitro-1H-imidazole-5-yl)piperazine-1-yl)methyl)-
1-substituted-1H1,2,3-triazole motifs are designed and synthesized
via click chemistry. The reaction of 1-(N1benzyl- 2-methyl-4-
nitro-1H-imidazole- 5-yl)-4-(prop-2-yn-1-yl) piperazine 5 as new
scaffold with diverse primary azides to selectively produce 1,4-
disubstituted-1,2,3-triazoles 9a-k, 10a-c and 11a-q.
Physicochemical methods: when 1H NMR, 13C NMR, and HRMS are
utilized to fully characterize all synthesized compounds. X-ray
structural determination and analysis for compound 9a is also
performed. The newly designed chromophores are assessed for their
antiproliferative potency against three selected human cancer cell
lines (MCF-7, HepG2, and PC3), and one normal cell line
(Dermal/Fibroblast). Compounds 9g and 9k have shown potent
activities against the MCF-7 cell line with IC50 values of (2.00 &
PLUSMN; 0.03 & mu;M) and (5.00 & PLUSMN; 0.01 & mu;M)
respectively. ADMET studies and Molecular docking investigations
are performed on the most active hybrid nitroimidazole derivatives
9g and 9k with 4-hydroxytamoxifen (4-OHT) at the human estrogen
receptor alpha (hER) during binding active sites to study the
ligand-protein interactions and free binding energies at atomic
levels. The triazole ring in the 9g derivative forms a hydrogen
bond with Asp58 with distance 3.2 & ANGS;. And it is found that
polar contact with His231 amino acid residue. In silico assessment
of the compounds showed very good pharmacokinetic properties based
on their physicochemical values, also the ADMET criteria of the
most active hybrid systems are within the acceptable range.

A dietary pattern rich in olive oil and raw vegetables is associated with lower mortality in Italian elderly subjects

BRITISH JOURNAL OF NUTRITION English Article
dietary patterns; elderly;
overall mortality; vegetables; olive oil CORONARY-HEART-DISEASE; FATTY-ACID-COMPOSITION; MEDITERRANEAN DIET; RISK-FACTORS; COLORECTAL-CANCER; COLON-CANCER; COHORT; CONSUMPTION; HEALTH; MEN

Dietary habits play an important role in healthy ageing. We have investigated the role of dietary patterns on overall mortality in a large series of Italian elderly, recruited in five EPIC cohorts in Northern (Varese and Turin), Central (Florence) and Southern Italy (Naples and Ragusa). A total of 5611 subjects (72.6 % women) aged 60 years or older, enrolled in 1993-1998, were prospectively followed (median 6.2 years), with 152 deaths (98 women). Four major dietary patterns were identified by using an exploratory factor analysis based on dietary information collected at enrolment. The associations between these dietary patterns and overall mortality were evaluated by Cox models adjusted for potential confounders. The 'Olive Oil & Salad' pattern, characterised by a high consumption of olive oil, raw vegetables, soups and poultry, emerged as being inversely associated with overall mortality in both crude and adjusted models. After

adjustment for gender, age and caloric intake, overall mortality was reduced by approximately 50 % in the highest quartile and a significant trend emerged (P=0.008). This association persisted after adjusting for several additional confounders (hazard ratio (HR) 0.50; 95 % CI 0.29, 0.86; P for trend = 0.02). An association of the 'Pasta & Meat' pattern (characterised by pasta, tomato sauce, red meat, processed meat, added animal fat, white bread and wine) with increased overall mortality was also suggested, but only for the highest quartile in a multivariate model. Dietary recommendations aimed at the Italian elderly population should support a dietary pattern characterised by a high consumption of olive oil, raw vegetables and poultry. TREATMENT; OVARIAN-CANCER Angiogenesis is a double-edged sword;

it is a mechanism that defines the boundary between health and disease. In spite of its central role in physiological homeostasis, it provides the oxygen and nutrition needed by tumor cells to proceed from dormancy if pro-angiogenic factors tip the balance in favor of tumor angiogenesis. Among pro-angiogenic factors, vascular endothelial growth factor (VEGF) is a prominent target in therapeutic methods due to its strategic involvement in the formation of anomalous tumor vasculature. In addition, VEGF exhibits immune-regulatory properties which suppress immune cell antitumor activity. VEGF signaling through its receptors is an integral part of tumoral angiogenic approaches. A wide variety of medicines have been designed to target the ligands and receptors of this pro-angiogenic superfamily. Herein, we summarize the direct and indirect molecular mechanisms of VEGF to demonstrate its versatile role in the context of cancer angiogenesis and current transformative VEGF-targeted strategies interfering with tumor growth.

Glands: Hsp90 Prospects for Differential Diagnosis and Treatment of Malignant Tumors INTERNATIONAL JOURNAL OF MOLECULAR SCIENCES English Article

salivary gland tumors; chaperone system; Hsp90; Hsp90 pathogenic; negative chaperonotherapy; Ganetespib; Hsp90 biomarker; differential diagnosis HEAT-SHOCK PROTEINS; KAPPA-B; INHIBITOR GANETESPIB; CARCINOMA-CELLS; BREAST-CANCER; EXPRESSION; APOPTOSIS; RESISTANCE; PATHWAY; GROWTH Salivary gland tumors represent a serious medical problem and new tools for differential diagnosis and patient monitoring are needed. Here, we present data and discuss the potential of molecular chaperones as biomarkers and therapeutic targets, focusing on Hsp10 and Hsp90. The salivary glands are key physiological elements but, unfortunately, the information and the means available for the management of their

pathologies, including cancer, are scarce. Progress in the study of carcinogenesis has occurred on various fronts lately, one of which has been the identification of the chaperone system (CS) as a physiological system with presence in all cells and tissues (including the salivary glands) that plays a role in tumor-cell biology. The chief components of the CS are the molecular chaperones, some of which belong to families of evolutionarily related molecules named heat shock protein (Hsp). We are quantifying and mapping these molecular chaperones in salivary glands to determine their possible role in the carcinogenetic mechanisms in these glands and to assess their potential as diagnostic biomarkers and therapeutic targets. Here, we report recent findings on Hsp10 and Hsp90 and show that the quantitative and topographic patterns of tissue Hsp90 are distinctive of malignant tumors and differentiate benign from malignant lesions. The Hsp90 results show a correlation between quantity of chaperone and tumor progression, which in turn calls for negative chaperonotherapy, namely, elimination/inhibition of the chaperone to stop the tumor. We found that in vitro, the Hsp90 inhibitor Ganetespiib is cytotoxic for the salivary gland UM-HACC-2A cell line. The drug, by interfering with the pro-survival NF-kappa B pathway, hampers cellular proliferation and migration, and favors apoptosis, and can, therefore, be considered a suitable candidate for future experimentation to develop a treatment for salivary gland tumors.

nanosensor; FRET; cancer; inflammation BREAST-CANCER; MEDITERRANEAN DIET; INDUCED-APOPTOSIS; RNA TRAFFICKING; LEUKEMIA-CELLS; PKC-DELTA; IN-VIVO; PROTEIN; EXPRESSION; ACTIVATION Flavonoids constitute the largest class of dietary phytochemicals, adding essential health value to our diet, and are emerging as key nutraceuticals. Cellular targets for dietary phytochemicals remain largely unknown, posing significant challenges for the regulation of dietary supplements and the understanding of how nutraceuticals provide health value. Here, we describe the identification of human cellular targets of apigenin, a flavonoid abundantly present in fruits and vegetables, using an innovative high-throughput approach that combines phage display with second generation sequencing. The 160 identified high-confidence candidate apigenin targets are significantly enriched in three main functional categories: GTPase activation, membrane transport, and mRNA metabolism/alternative splicing. This last category includes the heterogeneous nuclear ribonucleoprotein A2 (hnRNPA2), a factor involved in splicing regulation, mRNA stability, and mRNA transport. Apigenin binds to the C-terminal glycine-rich domain of hnRNPA2, preventing hnRNPA2 from forming homodimers, and therefore, it perturbs the alternative splicing of several human hnRNPA2 targets. Our results provide a framework to understand how dietary phytochemicals exert their actions by binding to many functionally diverse cellular targets. In turn, some of them may modulate the activity of a large number of downstream genes, which is exemplified here by the effects of apigenin on the alternative splicing activity of hnRNPA2. Hence, in contrast to small-molecule pharmaceuticals designed for defined target specificity, dietary phytochemicals affect a large number of cellular targets with varied affinities that, combined, result in their recognized health benefits.  Virgin olive oil phenols inhibit proliferation of
 human promyelocytic leukemia cells (HL60) by inducing apoptosis
 and differentiation JOURNAL OF NUTRITION English
 Article olive oil; phenols;
 apoptosis; differentiation; chemoprevention BREAST-CANCER RISK;
 RETINOIC ACID; MEDITERRANEAN DIET; FOOD GROUPS; LINE HL-60;
 HYDROXYTYROSOL; LIGNANS; CARCINOGENESIS; POTENTIATION; DERIVATIVES

Although epidemiologic evidence and animal studies suggest that olive oil may prevent the onset of cancer, the components responsible for such an effect and their mechanisms of action remain largely unknown. In the present study, we investigated the effect of a virgin olive oil phenol extract (PE) on proliferation, the cell cycle distribution profile, apoptosis, and

differentiation of the human promyelocytic cell line HL60. PE inhibited HL60 cell proliferation in a time- and concentration-dependent manner, as demonstrated by the viable cell count and 3-[4,5-dimethyl(thiazol-2yl)]-3,5-diphenyltetrazolium bromide (MTT) metabolism. Cell growth was completely blocked at a PE concentration of 13.5 mg/L; apoptosis was also induced as detected by fluorescence microscopy and flow cytometry. Determination of the cell cycle distribution by flow cytometry revealed an accumulation of cells in the G(0)/G(1) phase. Two compounds isolated from PE, the dialdehydic forms of elenoic acid linked to hydroxytyrosol (3,4-DHPEA-EDA) and to tyrosol (pHPEA-EDA), were shown to possess properties similar to those of PE; they account for a part of the powerful effects exerted by the complex mixture of compounds present in PE. The concentrations of the different compounds in PE were determined by HPLC, and the purity of 3,4-DHPEA-EDA and pHPEA-EDA was ascertained by NMR. Treatment with PE induced a differentiation in HL60 cells, which subsequently acquired the ability to produce superoxide ions and reduce nitroblue tetrazolium to formazan. These results support the hypothesis that polyphenols play a critical role in the anticancer activity of olive oil.

Endometrial cancer; Body mass index; Cohort HORMONE-THERAPY USE;
BREAST-CANCER; NUTRITIONAL EPIDEMIOLOGY; POSTMENOPAUSAL WOMEN;
MEDITERRANEAN DIET; HEME IRON; METAANALYSIS; CONSUMPTION;
VEGETABLES; FRUITS Information on the role of dietary patterns
and endometrial cancer risk is limited. We investigated whether
dietary patterns are associated with endometrial cancer risk among
women in the California Teachers Study cohort. Among 75,093
eligible women, 937 developed invasive endometrial cancer between
1995 and 2011. Multivariate Cox regression was performed to
estimate relative risks (RR) and 95 % confidence intervals (CI)
associated with five dietary patterns identified by principal
components factor analysis: "plant-based," "high protein/high
fat," "high carbohydrates," "ethnic," and "salad and wine." These
dietary patterns were not associated with endometrial cancer risk

overall (RR = 0.91, 95 % CI: 0.72, 1.15 for the highest vs. lowest quintile of the "plant-based" dietary pattern) or by menopausal status and hormone therapy use. Dietary patterns do not seem to be associated with endometrial cancer risk. MEDITERRANEAN DIET; BREAST-CANCER; FATTY-ACIDS; RISK;
ACCOMPLISHMENTS; INTERVENTIONS; SURVIVAL The 47th annual
meeting of the Society for Epidemiologic Research hosted 17

invited speakers charged by the Executive Committee with presenting some of the many ways that epidemiologists have improved the health of the general population. There were 9 "Then and Now" sessions that were structured to focus on how early epidemiologists overcame research hurdles and advanced health through innovative strategies. For most topics, a longstanding expert was paired with an excellent contemporary epidemiologist working in the area, and both were given the freedom to deliver an integrated story about epidemiology's temporal role in protecting and promoting public health. Epidemiologic discoveries in cardiovascular, cancer, and perinatal epidemiology were discussed on day 1, followed by discussions of accomplishments in reducing exposures that adversely impact health (nutrition, environment/occupation, and tobacco use) on day 2. Topics with relevancy for many aspects of epidemiology were presented on day 3, including infectious diseases, social forces, and causal thinking in epidemiologic research. Given the large number of outstanding senior and junior epidemiologists that attended the meeting, choosing speakers was a unique challenge. What became evident from all sessions was the passion that epidemiologists have for population health, tempered with concerns for remaining true to epidemiologic principles, the timely adoption of innovative methods, and the responsible interpretation of research findings. Beyond their crucial role in energy production, mitochondria harbor a distinct genome subject to epigenetic regulation akin to that of nuclear DNA. This paper delves into the nascent but rapidly evolving fields of mitoepigenetics and mitoepigenomics, exploring the sophisticated regulatory mechanisms governing mitochondrial DNA (mtDNA). These mechanisms encompass mtDNA methylation, the influence of non-coding RNAs (ncRNAs), and post-translational modifications of mitochondrial proteins. Together, these epigenetic modifications meticulously coordinate mitochondrial gene transcription, replication, and metabolism, thereby calibrating mitochondrial function in response to the dynamic interplay of intracellular needs and environmental stimuli. Notably, the dysregulation of mitoepigenetic pathways is increasingly implicated in mitochondrial dysfunction and a spectrum of human pathologies, including neurodegenerative diseases, cancer, metabolic disorders, and cardiovascular conditions. This comprehensive review synthesizes the current state of knowledge, emphasizing recent breakthroughs and innovations in the field. It discusses the potential of high-resolution mitochondrial epigenome mapping, the diagnostic and prognostic utility of blood or tissue mtDNA epigenetic markers, and the promising horizon of mitochondrial epigenetic drugs. Furthermore, it explores the transformative potential of mitoepigenetics and mitoepigenomics in precision medicine.

Exploiting a theragnostic approach to maintaining mitochondrial allostasis, this paper underscores the pivotal role of mitochondrial epigenetics in charting new frontiers in medical science. Eating Pattern Response to a Low-Fat Diet Intervention and Cardiovascular Outcomes in Normotensive Women: The Women's Health Initiative CURRENT DEVELOPMENTS IN NUTRITION English
Article cardiovascular

outcomes; normotensive women; low-fat diet; food choices; self-selected dietary change; vegetable protein CORONARY-HEART-DISEASE; BLOOD-PRESSURE; CARBOHYDRATE INTAKE; MEDITERRANEAN DIET; CLINICAL-TRIAL; BREAST-CANCER; RISK; MORTALITY; ADHERENCE; DESIGN

Background: Women without cardiovascular disease (CVD) or hypertension at baseline assigned to intervention in the Women's Health Initiative Dietary Modification (DM) trial experienced 30% lower risk of coronary heart disease (CHD), whereas results in women with hypertension or prior CVD could have been confounded by postrandomization use of statins. Objectives: Intervention participants reported various self-selected changes to achieve the 20% total fat goals. Reviewed are intervention compared with comparison group HRs for CHD, stroke, and total CVD in relation to specific dietary changes in normotensive participants. Methods: Dietary change was assessed by comparing baseline with year 1 FFQ data in women (n = 10,371) without hypertension or CVD at baseline with intake of total fat above the median to minimize biases due to use of the FFQ in trial eligibility screening. Results: Intervention participants self-reported compensating reduced energy intake from total fat by increasing carbohydrate and protein. Specifically they increased plant protein, with those in the upper quartile (increased total protein by $\geq 3.3\%$ of energy) having a CHD HR of 0.39 (95% CI: 0.22, 0.71), compared with 0.92 (95% CI: 0.57, 1.48) for those in the lower quartile of change (decreased total protein $\geq 0.6\%$ of energy), with P-trend of 0.04.

CHD HR did not vary significantly with change in percentage energy from carbohydrate, and stroke HR did not vary significantly with any macronutrient changes. Scores reflecting adherence to recommended dietary patterns including the Dietary Approaches to Stop Hypertension Trial and the Healthy Eating Index showed favorable changes in the intervention group. Conclusions: Intervention group total fat reduction replaced with increased carbohydrate and some protein, especially plant-based protein, was related to lower CHD risk in normotensive women without CVD who reported high baseline total fat intake. identifies conserved domains essential for proper subcellular localization and transcriptional repression JOURNAL OF CELLULAR BIOCHEMISTRY English Article

ZNF703; NLZ1; NET FAMILY; CONSERVED DOMAINS; NUCLEAR LOCALIZATION HUMAN BREAST-CANCER; ZINC-FINGER GENE; NUCLEAR-LOCALIZATION; 8P11-12 AMPLICON; DROSOPHILA-MELANOGASTER; SP-FAMILY; EXPRESSION; PROTEIN; SIGNALS; POLYADENYLATIONNET family members have recently emerged as important players in the development of multiple structures, from the trachea of fly larvae to the vertebrate eye and human breast cancers. However, their mechanisms of action are still poorly understood, and we lack a detailed characterization of their functional domains, as well as gene expression patterns particularly in adult mammals. Here, we present a characterization of human NLZ1/ZNF703 (NocA-like zinc finger 1/Zinc finger 703), one of the two human NET family member genes. We show that the gene is ubiquitously expressed in adult human and mouse tissues, that three mRNA species with the same coding sequence are generated by alternative polyadenylation, and that the encoded protein contains six evolutionarily conserved domains, three of which are specific to NET proteins. Finally, we present functional evidence that these domains are necessary for proper subcellular distribution of and transcription repression by the NLZ1 protein, but not for its interaction with Groucho family co-repressors. Arifler, Dizem; MacAulay, Calum; Follen, Michele;
Richards-Kortum, Rebecca Spatially resolved
reflectance spectroscopy for diagnosis of cervical precancer:
Monte Carlo modeling and comparison to clinical measurements
JOURNAL OF BIOMEDICAL OPTICS English Article
reflectance spectroscopy; fiber-
optic probes; Monte Carlo modeling; cervical intraepithelial
neoplasia FIBROPTIC PROBE DESIGNS; DIFFUSE-REFLECTANCE; IN-
VIVO; OPTICAL-PROPERTIES; LIGHT-SCATTERING; BREAST-CANCER;
INTRINSIC FLUORESCENCE; EPITHELIAL TISSUE; PATH-LENGTH; ABSORPTION
We present Monte Carlo modeling studies to provide a
quantitative understanding of contrast observed in spatially
resolved reflectance spectra of normal and highly dysplastic
cervical tissue. Simulations have been carried out to analyze the
sensitivity of spectral measurements to a range of changes in
epithelial and stromal optical properties that are reported to
occur as dysplasia develops and to predict reflectance spectra of
normal and highly dysplastic tissue at six different source-
detector separations. Simulation results provide important
insights into specific contributions of different optical
parameters to the overall spectral response. Predictions from
simulations agree well with in vivo measurements from cervical
tissue and successfully describe spectral differences observed in
reflectance measurements from normal and precancerous tissue
sites. Penetration depth statistics of photons detected at the six
source-detector separations are also presented to reveal the
sampling depth profile of the fiber-optic probe geometry
simulated. The modeling studies presented provide a framework to
meaningfully interpret optical signals obtained from epithelial
tissues and to optimize design of optical sensors for in vivo
reflectance measurements for precancer detection. Results from
this study can facilitate development of analytical photon
propagation models that enable inverse estimation of
diagnostically relevant optical parameters from in vivo
reflectance measurements. (c) 2006 Society of Photo-Optical

Richard M.; de Gramont, Aimery End points for colon
cancer adjuvant trials: Observations and recommendations based on
individual patient data from 20,898 patients enrolled onto 18
Randomized trials from the ACCENT group JOURNAL OF CLINICAL
ONCOLOGY English Article

STAGE-II; COLORECTAL-CANCER; DUKES B;
FLUOROURACIL; LEUCOVORIN; CHEMOTHERAPY; LEVAMISOLE; EFFICACY;
THERAPY; BREAST Purpose The traditional end point for colon
adjuvant clinical trials is overall survival (OS). We previously
validated disease-free survival (DFS) after 3-year follow-up as an
excellent predictor of 5-year OS results. Here we explore shorter
term DFS and OS end points, as well as stage dependency. Methods
Individual patient data from 18 phase III trials including 43 arms
and 20,898 patients were pooled. Association measures included
correlation of event rates within arms, correlation of hazard
ratios (HRs) between arms, trial level significance comparisons
(via log-rank testing), and a formal surrogacy model. Results DFS
at earlier times was less accurate in predicting OS than 3-year
DFS, but 2-year DFS remained a strong predictor. DFS with 1-year
minimum follow-up demonstrated perfect negative predicted value;
all trials negative at 1 year for DFS were negative for 5-year OS.
OS with 3-year minimum follow-up was also an excellent predictor
for 5-year OS; OS at earlier time points provided inaccurate
prediction. The association between 3-year DFS and 5-year OS was
greater for stage III patients; correlation of HR within trials
was 0.92 (95% CI, 0.85 to 0.95) for stage III patients and 0.70
(95% CI, 0.44 to 0.80) for stage II patients. Conclusion DFS
outcomes after 2- or 3-year median follow- up are excellent
predictors of 5-year OS. DFS outcomes are appropriate for trials
in which the majority of patients are stage III. DFS after 2-or 3-
year median follow-up should be considered as the primary end
point in future colon adjuvant trials. Mayo Clin, N Cent Canc

Urinary Biomarkers of Whole Grain Wheat Intake Identified by
 Non-targeted and Targeted Metabolomics Approaches SCIENTIFIC
 REPORTS English Article

CAUSE-SPECIFIC MORTALITY; DIETARY FIBER INTAKE;
 ALKYLRESORCINOL METABOLITES; COLORECTAL-CANCER; CEREAL FIBER;
 BILE-ACIDS; MEDITERRANEAN DIET; MASS-SPECTROMETRY; PHENOLIC-ACIDS;
 WEIGHT CHANGE Mounting evidence suggests that whole grain (WG)
 intake plays an important role in chronic disease prevention.
 However, numerous human studies have failed to produce clear-cut
 conclusions on this topic. Here, a combination of non-targeted and
 targeted metabolomics approaches, together with kinetic studies,
 was used to investigate biomarkers of WG wheat intake and further
 explore the diet-disease associations. Via these integrated
 approaches, forty-one compounds were identified as the most

discriminating endogenous metabolites after WG versus refined grain (RG) wheat bread consumption. The corresponding biological assessment of these endogenous changes suggests that, in contrast to RG consumption, WG wheat consumption may facilitate antioxidant defense systems and moderate the risk factors of cancer, cardiovascular diseases, and other chronic diseases. A panel of urinary markers consisting of seven alkylresorcinol metabolites and five benzoxazinoid derivatives as specific biomarkers, as well as five phenolic acid derivatives, was also established to cover multiple time points and longer time periods for correctly and objectively monitoring WG wheat intake. Through these findings, we have established a comprehensive biomarker pool to better assess WG wheat consumption, and to monitor the endogenous changes that are linked to health effects of WG wheat consumption. Dietary guidelines; Greece; Childhood obesity; Adolescent obesity CORONARY-HEART-DISEASE; COLORECTAL-CANCER RISK; CARDIOVASCULAR-DISEASE; CHILDHOOD OBESITY; FISH CONSUMPTION; MEAT CONSUMPTION; MEDITERRANEAN DIET; PHYSICAL-ACTIVITY; VEGETABLE INTAKE; ADHERENCE RATES Objective: Dietary guidelines are an essential policy tool for facilitating optimal dietary patterns and healthy eating behaviours. We report: (i) the methodological approach adopted for developing the National Dietary Guidelines of

Greece (NDGGr) for Infants, Children and Adolescents; and (ii) the guidelines for children aged 1-18 years. Design: An evidence-based approach was employed to develop food-based recommendations according to the methodologies of the WHO, FAO and European Food Safety Authority. Physical activity recommendations were also compiled. Food education, healthy eating tips and suggestions were also provided. Setting: The NDGGr encompass food-based nutritional and physical activity recommendations for promoting healthy dietary patterns and eating behaviours and secondarily to serve as a helpful tool for the prevention of childhood overweight and obesity. Results: The NDGGr include food-based recommendations, food education and health promotion messages regarding: (i) fruits; (ii) vegetables; (iii) milk and dairy products; (iv) cereals; (v) red and white meat; (vi) fish and seafood; (vii) eggs; (viii) legumes; (ix) added lipids, olives, and nuts; (x) added sugars and salt; (xi) water and beverages, and (xii) physical activity. A Nutrition Wheel, consisting of the ten most pivotal key messages, was developed to enhance the adoption of optimal dietary patterns and a healthy lifestyle. The NDGGr additionally provide recommendations regarding the optimal frequency and serving sizes of main meals, based on the traditional Greek diet. Conclusions: As a policy tool for promoting healthy eating, the NDGGr have been disseminated in public schools across Greece.

and Occupational Class and Leukocyte Telomere Length in the Male
Population AMERICAN JOURNAL OF MENS HEALTH English
Article foods groups; dietary

patterns; occupational class; serum lipids; telomere length

LIFE-STYLE FACTORS; CORONARY-HEART-DISEASE; MEDITERRANEAN
DIET; OXIDATIVE DAMAGE; PREDIMED-NAVARRA; BREAST-CANCER; RISK-
FACTORS; RED MEAT; ASSOCIATION; WASTE Telomeres contain TTAGGG
repetitive sequences and are located at the end of human
chromosomes. Telomere dysfunction is associated with some age-
related and chronic diseases, but its relationship with foods,
dietary patterns, and occupational class in the young male
population is not yet known. In this cross-sectional study, 300
healthy men, residents of Tehran, aged 25-40 years were enrolled
from January to December 2016. We employed a cross-sectional study
of 300 healthy people, residents of Tehran, aged 25-40 years. A
food frequency questionnaire was used to obtain food intakes of
all participants and converted into actual food intake (g/day).
The principal components analysis was used to determine dietary
patterns and other demographic characteristics. Leukocyte telomere
length (TL) was measured by quantitative real-time polymerase
chain reaction (PCR) to measure number of telomere repeat copy
number (T) to the relative number of 36B4 copies (S) (T/S ratio).
T/S in office-workers, waste recyclers, and other workers were
1.22 +/- 0.4, 1.08 +/- 0.3, and 1.094 +/- 0.34, respectively. The
results of multivariate linear regression adjusted for age, body
mass index (BMI), and smoking were showed that whole grains (=
0.02; p = .05), refined grains, fruits and vegetables, fish and
dairy products were associated with an increase in log-T/S, but
consumption of nuts and seeds (= -0.00072; p = .06), meats (= -
0.00043; p = .9), produced meats (= -0.00238; p = .03), oils and
solid fats (= -0.00146; p = .03) had a negative relationship with
log-T/S in all studied occupational classes. A positive
relationship was reported between the healthy (= 0.017; p = .2)
and traditional dietary pattern (= 0.012; p = .4) with log-T/S,
but western pattern identified negative relationship (= -0.004; p
= .7). Adherence to a healthy (with consumption whole grains,
refined grains, dairy, and cereals) and then traditional pattern
with increased consumption of fruits, vegetables and whole grains,
fish and dairy products are necessary to prevent TL destruction in
all studied occupational classes. [Karimi, Behrooz] Arak Univ Med

Consumption and Lung Cancer Risk: Results from Two Large
Observational Studies CANCER EPIDEMIOLOGY BIOMARKERS & PREVENTION
English Article

DIETARY FLAVONOID INTAKE; CAUSE-SPECIFIC MORTALITY;
NIH-AARP DIET; MEDITERRANEAN DIET; ALMOND CONSUMPTION; COLORECTAL-
CANCER; FISH CONSUMPTION; ETIOLOGY EAGLE; MALE SMOKERS; DNA-DAMAGE

Background: Epidemiologic evidence on the association between nut consumption and lung cancer risk is limited. Methods: We investigated this relationship in the Environment and Genetics in Lung Cancer Etiology (EAGLE) study, a population-based case-control study, and the National Institutes of Health (NIH) American Association of Retired Persons (AARP) Diet and Health Study, a prospective cohort. We identified 2,098 lung cases for EAGLE and 18,533 incident cases in AARP. Diet was assessed by food frequency questionnaire for both studies. Multivariable ORs and HRs and respective 95% confidence intervals (CI) were calculated using unconditional logistic regression and Cox proportional hazards regression for EAGLE and AARP, respectively. Results:

Higher frequency of intake of nut consumption was inversely associated with overall lung cancer risk (highest vs. lowest quintile, OREAGLE = 0.74; 95% CI, 0.57-0.95; HRAARP = 0.86; 95% CI, 0.81-0.91), regardless of smoking status. Results from the prospective cohort showed similar associations across histologic subtypes and a more pronounced benefits from nut consumption for those who smoked 1 to 20 cigarettes/day (OREAGLE = 0.61; 95% CI, 0.39-0.95; HRAARP = 0.83; 95% CI, 0.74-0.94). Conclusions: Nut consumption was inversely associated with lung cancer in two large population-based studies, and associations were independent of cigarette smoking and other known risk factors. Impact: To our knowledge, this is the first study that examined the association between nut consumption and lung cancer risk by histologic subtypes and smoking intensity.  An Industrial and Sustainable Platform for the Production of Bioactive Micronized Powders and Extracts Enriched in Polyphenols From *Olea europaea* L. and *Vitis vinifera* L. Wastes
 FRONTIERS IN NUTRITION English Article

Olea europaea L.; *Vitis vinifera* L.; agro-industrial wastes; circular economy; sustainable extraction; polyphenol-enriched extracts; micronized powders; biological activities VIRGIN OLIVE-OIL; MINOR POLAR COMPOUND; GRAPE SEED EXTRACT; PHENOLIC-COMPOUNDS; COLORECTAL-CANCER; OLEA-EUROPAEA; MEDITERRANEAN DIET; MILL WASTEWATERS; FUNCTIONAL FOOD.; OXIDATIVE STRESS

In the last few years, literature data have reported that health status is related to the consumption of foods rich in polyphenols, bioactive compounds found in the plant world, in particular in vegetables and fruit. These pieces of scientific evidence have led to an increase in the demand for functional foods and drinks enriched in polyphenols, so that plant materials are more and more requested. The availability of food and agricultural wastes has adverse effects on the economy, environment, and human health. On the other hand, these materials are a precious source of bioactive compounds as polyphenols. Their recovery and reuse from wastes are according to the circular economy strategy, which has introduced the "zero waste concept." However, the process is convenient from an economic and environmental point of view only if the final products are standardized and obtained using sustainable and industrial technologies. In this panorama, this paper describes an industrial and sustainable platform for the production of micronized powders and extracts enriched in polyphenols from *Olea europaea* L. and *Vitis vinifera* L. wastes that are useful for food, cosmetics, and pharmaceuticals sectors. The platform is based on drying plant materials, extraction of polyphenols through membrane technologies with water, and, when necessary, the concentration of the final fractions under vacuum evaporation. All powders and extracts were characterized by high-performance liquid chromatography-diode array detector-mass spectrometry analysis to define the qualitative and quantitative content of bioactive compounds and insure their standardization and reproducibility. The chromatographic profiles evidenced the presence of secoiridoids, flavones, flavonols, anthocyanins, hydroxycinnamic acids, catechins, and condensed tannins. An overview of the biological activities of the main polyphenols present in *Olea europaea* L. and *Vitis vinifera* L. powders and extracts is reported because of biomedical applications.

Exploring and Expanding Secondary Findings Through

Exome Sequencing in the Turkish Population ANNALS OF HUMAN GENETICS English Article

ACMG; cardiovascular disease; cancer; exome sequencing; secondary findings FAMILIAL MEDITERRANEAN FEVER; FANCONI-ANEMIA PATHWAY; HYPERTROPHIC CARDIOMYOPATHY; CLINICAL EXOME; INCIDENTAL FINDINGS; MEDICAL GENETICS; AMERICAN-COLLEGE; POLICY STATEMENT; BREAST-CANCER; ACMG Introduction Exome-sequencing (ES) methods enable accurate diagnosis in challenging cases and uncover secondary findings (SFs) potentially linked to life-threatening or preventable diseases. The American College of Medical Genetics and Genomics (ACMG) publishes a list detailing which SFs should be reported and regularly updates it. We aimed to compare results across different SF versions in patients and explore additional SFs to identify potential new recommendations for SF reporting. Methods We conducted a retrospective analysis of 724 patients to identify ACMG SFs using the QIAGEN Clinical Insight (QCI) Interpret database. Furthermore, we investigated pathogenic/likely pathogenic variants in cancer and cardiovascular disease genes not listed in ACMG SFs, as well as genes associated with common diseases prevalent in our country. Methods ACMG SF v3.2 variants were identified in 56 patients (7.7%), with no observed differences between ACMG v3.1 and v3.2. Additionally, our analysis revealed that 208 patients harbored non-ACMG SF variants. Conclusion In this study, we focused on known SFs and identified additional variants that could be considered as new recommendations. While expanding the list of SFs can pose challenges during analyses and genetic counseling, a thoughtfully curated SF list has the potential to enhance patient care and improve clinical outcomes. Disparities in Cancer Incidence among Chinese Population
 versus Migrants to Developed Regions: A Population-Based
 Comparative Study CANCER EPIDEMIOLOGY BIOMARKERS & PREVENTION
 English Article
 GENOME-WIDE ASSOCIATION; LUNG-CANCER; BREAST-CANCER;
 SUSCEPTIBILITY LOCI; MEDITERRANEAN DIET; VEGETABLE INTAKE;
 PROSTATE-CANCER; AIR-POLLUTION; IDENTIFIES 2; LARGE-BOWEL

Background: The incidence of cancer was determined by
 genetic and environmental factors and varied across the world. The
 discrepancies in cancer profile among Chinese people living in
 different regions remained obscure. Methods: Chinese people living
 in urban Shanghai, Hong Kong, Taiwan, Macau, Singapore, and Los
 Angeles were included in this study. The cancer case data and
 population data were collected from either the Cancer Incidence in
 Five Continents Plus database or the regional cancer registry. A
 rate model was applied to examine the regional differences in
 cancer risk with Shanghai set as the reference. Results: From 1983
 to 2013, the cancer profiles in most regions were changed.
 Significant differences in cancer incidence, by sex, period, and
 age, were detected across regions. The most pronounced disparities
 were found between Shanghai people and American Chinese in Los
 Angeles. For cancer site, the most significant differences were
 detected in prostate, gastrointestinal, gynecologic, oral cavity
 and pharynx, and brain and central nervous system (CNS) cancers.
 Specifically, Shanghai was significantly higher in stomach, liver,
 esophageal, pancreatic, and brain and CNS cancers, while lower in
 colon, prostate, breast, cervical, and oral cavity and pharynx
 cancers compared with the other five populations. Conclusions:
 Cancer profile was distinct across Chinese populations, which
 shared a similar genetic background but lived in different
 regions. The disparities indicate that cancer development was
 majorly determined by environmental factors, and suggests that
 region-tailored cancer prevention strategies were warranted.
 Impact: The cancer patterns in populations sharing the same
 genetic background were significantly influenced by different
 living conditions. [Liu, Zhenqiu; Cai, Ning; Jiang, Yanfeng;

SIGNAL-TRANSDUCTION; MOLECULAR-CLONING; TYROSINE KINASE; PLASMA-MEMBRANE; COWDEN-DISEASE; GROWTH-FACTORS

Introduction: Akt activation is involved in the pathogenesis of inherited thyroid cancer in Cowden's syndrome and in sporadic thyroid cancers. In cell culture, Akt regulates thyroid cell growth and survival; but recent data suggest that Akt also regulates cell motility in non-thyroid cell lines. We therefore sought to evaluate the role of Akt in thyroid cancer progression. Methods: We evaluated 46 thyroid cancer, 20 thyroid follicular adenoma, and adjacent normal tissues samples by immunohistochemistry for activated Akt (pAkt), Akt 1, 2, and 3, and p27 expression. Immunoblots were performed in 14 samples. Results: Akt activation was identified in 10/10 follicular cancers, 26/26 papillary cancers, and 2/10 follicular variant of papillary cancers, but in only 4/66 normal tissue samples and 2/10 typical benign follicular adenomas. Immunoactive pAkt was greatest in regions of capsular invasion; and was localised to the nucleus in follicular cancers and the cytoplasm in papillary cancers, except for invasive regions of papillary cancers where it localised to both compartments. Immunoactive Akt 1, but not Akt 2 or Akt 3, correlated with pAkt localisation, and nuclear pAkt was associated with cytoplasmic expression of p27. In vitro studies using human thyroid cancer cells demonstrated that nuclear translocation of Akt 1 and pAkt were associated with cytoplasmic p27 and cell invasion and migration. Cell migration and the localisation of Akt 1, pAkt, and p27 were inhibited by PI3 kinase, but not MEK inhibition. Discussion: These data suggest an important role for nuclear activation of Akt 1 in thyroid cancer progression.

J Kaluza, J; Håkansson, N; Harris, HR; Orsini, N; Michaëlsson, K; Wolk, A Kaluza, J.; Hakansson, N.; Harris, H. R.; Orsini, N.; Michaelsson, K.; Wolk, A. Influence of anti-inflammatory diet and smoking on mortality and survival in men and women: two prospective cohort studies JOURNAL OF INTERNAL MEDICINE English Article
anti-inflammatory index; diet; inflammation; mortality; prospective study; survival time LOW-GRADE INFLAMMATION; OBSTRUCTIVE PULMONARY-DISEASE; INDIVIDUAL-PARTICIPANT-DATA; LEUKOCYTE TELOMERE LENGTH; COLORECTAL-CANCER RISK; CARDIOVASCULAR-DISEASE; MEDITERRANEAN DIET; ALL-CAUSE; MULTIPLE IMPUTATION; CIGARETTE-SMOKING Background The associations between an anti-inflammatory diet and both all-cause and cause-specific mortality have been studied previously; however, the influence of an anti-inflammatory diet on survival time has not been investigated. Moreover, the potential modification of these associations by smoking status remains unclear. Objective The aims of this study were to examine the associations between an anti-inflammatory diet index (AIDI) and all-cause and cause-specific mortality, to determine the association between the AIDI and differences in survival time and to assess effect modification by smoking status. Methods The study population included 68 273 Swedish men and women (aged 45-83 years) at baseline. The anti-inflammatory potential of the diet was estimated using the validated AIDI, which includes 11 potential anti-inflammatory and five potential pro-inflammatory foods. Cox proportional hazards and Laplace regression were used to estimate hazard ratios and differences in survival time. Results During 16 years of follow-up (1 057 959 person-years), 16 088 deaths [5980 due to cardiovascular disease (CVD) and 5252 due to cancer] were recorded. Participants in the highest versus lowest quartile of the AIDI had lower risks of all-cause (18% reduction, 95% CI: 14-22%), CVD (20%, 95% CI: 14-26%) and cancer (13%, 95% CI: 5-20%) mortality. The strongest inverse associations between the highest and lowest quartiles of AIDI and risk of mortality were observed in current smokers: 31%, 36% and 22% lower risks of all-cause, CVD and cancer mortality, respectively. The difference in survival time between current smokers in the lowest AIDI quartile and never smokers in the highest quartile was 4.6 years. Conclusion Adherence to a diet with high anti-inflammatory potential may reduce all-cause, CVD and cancer mortality and prolong survival time especially amongst smokers. Phytoestrogens as natural prodrugs in cancer prevention: dietary flavonoids PHYTOCHEMISTRY REVIEWS
English Article; Proceedings Paper International Symposium of the Phytochemical-Society-of-Europe SEP 23-26, 2008

prevention; CYP1; Flavonoids; Metabolism ARYL-HYDROCARBON RECEPTOR; CYTOCHROME P450-MEDIATED METABOLISM; HUMAN PROSTATE-CANCER; CELL-CYCLE ARREST; BREAST-CANCER; IN-VITRO; MEDITERRANEAN DIET; CYP1 ENZYMES; INHIBITION; APOPTOSIS There are many reasons why vegetables and fruits may protect against cancer. As well as containing vitamins and minerals, which help keep the body healthy and strengthen the immune system, they are also good sources of biologically active compounds, which can help to protect cells in the body from damage that can lead to cancer. Notably, dietary flavonoids and other polyphenols are thought to have an important role as chemopreventive agents. Most studies on the possible mechanism of the chemopreventive action of dietary compounds have assumed that free hydroxyl groups of flavonoids and other polyphenols are necessary for their biological effects. However, in the human body dietary polyphenols are rapidly conjugated by glucuronosyltransferases and sulfotransferases, two enzymes that are abundantly present in the small intestine and liver, through which all of the oral dose must pass. Thus, most polyphenols that have been studied, e.g. quercetin, kaempferol, diosmetin, and resveratrol, would not be expected to reach internal organs beyond sites directly along the gastrointestinal tract. When the hydroxyl groups in polyphenols are methylated, the resulting compounds are much less prone to glucuronidation and sulfation. Thus methoxylated compounds are more metabolically

stable, increasing their bioavailability. The peel of various Citrus species can contain high concentrations of poly methoxy flavones, whereas the juice mainly contains hydroxylated flavones. At present, very little is known about the mechanisms by which methoxylated flavones may affect growth and development of tumour cells. Recently, it was shown that tumour specific enzymes can catalyze the O-demethylation of methoxylated flavones, resulting in the formation of flavones with free hydroxyl groups. We propose that demethylation of methoxylated flavones is another example of bioactivation of naturally occurring prodrugs. [Arroo,

polyphenols targeting vitagenes for chemoprevention and therapy: Relevance to novel anti-cancer interventions and mini-brain organoid technology FREE RADICAL BIOLOGY AND MEDICINE

English Article Brain tumors; Vitagenes; Oxidative stress; Polyphenols; Chemoprevention; Hormesis; Nanoparticles; Mini-brain cancer organoids HEAT-SHOCK PROTEINS; HEME OXYGENASE-1 EXPRESSION; ENDOTHELIAL-CELL MIGRATION; COLORECTAL-CANCER CELLS; REDUCES IN-VITRO; INDUCED APOPTOSIS; MEDITERRANEAN DIET; STEM-CELLS; SIGNALING PATHWAYS; PLGA NANOPARTICLES The scientific community, recently, has focused notable attention on the chemopreventive and therapeutic effects of dietary polyphenols for human health. Emerging evidence demonstrates that polyphenols, flavonoids and vitamins counteract and neutralize genetic and environmental stressors, particularly oxidative stress and inflammatory process closely connected to cancer initiation, promotion and progression. Interestingly, polyphenols can exert antioxidant or pro-oxidant cytotoxic effects depending on their endogenous concentration. Notably, polyphenols at high dose act as pro-oxidants in a wide type of cancer cells by inhibiting Nrf2 pathway and the expression of antioxidant vitagenes, such as NAD(P)H-quinone oxidoreductase (NQO1), glutathione transferase (GT), GPx, heme oxygenase-1 (HO-1), sirtuin-1 (Sirt1) and thioredoxin (Trx) system which play an

essential role in the metabolism of reactive oxygen species (ROS), detoxification of xenobiotics and inhibition of cancer progression, by inducing apoptosis and cell cycle arrest according to the hormesis approach. Importantly, mutagenesis of Nrf2 pathway can exacerbate its "dark side" role, representing a crucial event in the initiation stage of carcinogenesis. Herein, we review the hormetic effects of polyphenols and nanoencapsulated-polyphenols in chemoprevention and treatment of brain tumors via activation or inhibition of Nrf2/vitagenes to suppress carcinogenesis in the early stages, and thus inhibit its progression. Lastly, we discuss innovative preclinical approaches through mini-brain tumor organoids to study human carcinogenesis, from basic cancer research to clinical practice, as promising tools to recapitulate the arrangement of structural neuronal tissues and biological functions of the human brain, as well as test drug toxicity and drive personalized and precision medicine in brain cancer.

Rebalancing immune homeostasis in combating
disease: The impact of medicine food homology plants and gut
microbiome PHYTOMEDICINE English Article

Medicinal and food homologous; Gut
microbiome; Immune regulation; disease INNATE LYMPHOID-CELLS;
CHAIN FATTY-ACIDS; CD103(+)CD11B(+) DENDRITIC CELLS; REGULATORY T-
CELLS; ROR-GAMMA-T; MEDITERRANEAN DIET; PARKINSONS-DISEASE;
COLORECTAL-CANCER; LUNG-CANCER; TRYPTOPHAN-METABOLISM

Background: Gut microbiota plays an important role in
multiple human physiological processes and an imbalance in it,
including the species, abundance, and metabolites can lead to
diseases. These enteric microorganisms modulate immune homeostasis
by presenting a myriad of antigenic determinants and microbial
metabolites. Medicinal and food homologous (MFH) plants, edible
herbal materials for both medicine and food, are important parts
of Traditional Chinese Medicine (TCM). MFH plants have drawn much
attention due to their strong biological activity and low
toxicity. However, the interplay of MFH and gut microbiota in
rebalancing the immune homeostasis in combating diseases needs
systematic illumination. Purpose: The review discusses the
interaction between MFH and gut microbiota, including the effect
of MFH on the major group of gut microbiota and the metabolic
effect of gut microbiota on MFH. Moreover, how gut microbiota
influences the immune system in terms of innate and adaptive
immunity is addressed. Finally, the immunoregulatory mechanisms of
MFH in regulation of host pathophysiology via gut microbiota are
summarized. Methods: Literature was searched, analyzed, and
collected using databases, including PubMed, Web of Science, and
Google Scholar using relevant keywords. The obtained articles were
screened and summarized by the research content of MFH and gut
microbiota in immune regulation. Results: The review demonstrates
the interaction between MFH and gut microbiota in disease
prevention and treatment. Not only do the intestinal
microorganisms and intestinal mucosa constitute an important
immune barrier of the human body, but also lymphoid tissue and
diffused immune cells within the mucosa participate in the
response of innate immunity and adaptive immunity. MFH modulates
immune regulation by affecting intestinal flora, helps maintain
the balance of the immune system and interfere with the occurrence
and development of a broad category of diseases. [Xia, Lu; Li,

epidemiology; policy CORONARY-HEART-DISEASE; SUGAR-SWEETENED
BEVERAGES; FAT DIETARY PATTERN; TOTAL-ENERGY-INTAKE; MEASUREMENT
ERROR; BLOOD-PRESSURE; BREAST-CANCER; SELF-REPORT; CARDIOVASCULAR-
DISEASE; MEDITERRANEAN DIET Nutritional research and policies have
been criticized for relying on observational evidence, using self-
report diet assessment methods, and supposedly being unable to
present a consensus on what constitutes a healthy diet. In
particular, it is often asserted that for progress to occur in
nutrition science, large, simple trials, which have worked well in
evaluating the efficacy of drugs, need to replace most
observational research and small trials in nutrition. However,
this idea is infeasible, and is unlikely to advance nutritional
sciences or improve policies. This article addresses some commonly
held and unfounded "myths" surrounding dietary assessments, effect
sizes, and confounding, demonstrating how carefully conducted
observational studies can provide reliable and reproducible
evidence on diet and health. Also, there is a strong consensus
among nutritional researchers and practitioners about the basic
elements of a healthy diet. To move forward, we should continue to
improve study design and diet assessment methodologies, reduce
measurement errors, and leverage new technologies. Advances in the
field lie in coalescing evidence from multiple study designs,
methodologies, and technologies, and translating what we already
know into policy and practice, so we can improve diet quality and
enhance health in an equitable and sustainable manner across the
world. [Satija, Ambika; Stampfer, Meir J.; Rimm, Eric B.;

Development and Use of a Traditional Mexican Diet Score in
Relation to Systemic Inflammation and Insulin Resistance among
Women of Mexican Descent JOURNAL OF NUTRITION

English Article C-
reactive protein; HOMA-IR; insulin resistance; Mexican descent;
Mexican diet score; obesity; systemic inflammation; triglycerides
FOOD FREQUENCY QUESTIONNAIRE; HOMEOSTASIS MODEL ASSESSMENT;
C-REACTIVE PROTEIN; BODY-MASS INDEX; ENDOTHELIAL DYSFUNCTION;
MEDITERRANEAN DIET; CARDIOVASCULAR-DISEASE; PLASMA-CONCENTRATIONS;
AMERICAN POPULATION; BREAST-CANCER Background: Women of
Mexican descent are disproportionately affected by obesity,
systemic inflammation, and insulin resistance (IR). Available
approaches used to give scores to dietary patterns relative to
dietary guidelines may not effectively capture traditional diets
of Mexicans, who comprise the largest immigrant group in the
United States. Objectives: We characterized an a priori
traditional Mexican diet (MexD) score high in corn tortillas,
beans, soups, Mexican mixed dishes (e.g., tamales), fruits,
vegetables, full-fat milk, and Mexican cheeses and low in refined
grains and added sugars and evaluated the association of the MexD
score with systemic inflammation and IR in 493 postmenopausal
participants in the Women's Health Initiative (WHI) who are of
Mexican ethnic descent. Methods: The MexD score was developed from
the baseline (1993-1998) WHI food frequency questionnaire, which
included Hispanic foods and was available in Spanish. Body mass
index (BMI) was computed from baseline measured weight and height,
and ethnicity was self-reported. Outcome variables were high
sensitivity C-reactive protein (hsCRP), glucose, insulin,
homeostasis model assessment of insulin resistance (HOMA-IR), and
triglyceride concentrations measured at follow-up (2012-2013).
Multivariable linear and logistic regression models were used to
test the associations of the MexD score with systemic inflammation
and IR. Results: The mean +/- SD MexD score was 5.8 +/- 2.1 (12
maximum points) and was positively associated with intakes of
carbohydrates, vegetable protein, and dietary fiber and inversely

associated with intakes of added sugars and total fat ($P < 0.01$). Women with high compared with low MexD scores, consistent with a more-traditional Mexican diet, had 23% and 15% lower serum hsCRP ($P < 0.05$) and insulin concentrations, respectively ($P < 0.05$). Baseline BMI modified these associations such that lower MexD scores were associated with higher insulin and HOMA-IR in overweight/obese women (P -interaction < 0.05). Conclusion: These findings suggest that greater adherence to a traditional Mexican diet could help reduce the future risk of systemic inflammation and IR in women of Mexican descent. Santos-Buelga, C.; Gonzalez-Manzano, S. WINE AND HEALTH RELATIONSHIPS. A QUESTION OF MODERATION? CIENCIA E TECNICA VITIVINICOLA English Article

Red wine; alcohol; health; epidemiological studies; coronary heart disease; adverse effects CORONARY-HEART-

DISEASE; CARDIOVASCULAR RISK-FACTORS; ALCOHOLIC BEVERAGE
 CONSUMPTION; MEDITERRANEAN-STYLE DIET; ALL-CAUSE MORTALITY; RED
 WINE; MYOCARDIAL-INFARCTION; BLOOD-PRESSURE; BEER-DRINKING;
 BREAST-CANCER Evidences accumulated over the last thirty years
 suggest that light to moderate alcohol consumption, especially in
 the form of red wine, can have beneficial effects for health.
 Those benefits mostly refer to improvement in cardiovascular
 health, although relationships with a lower risk of other
 pathologies such as type 2 diabetes, dementia or cognitive decline
 in old age have also been established. Most evidences derive from
 observational studies or from in vitro or animal assays, whereas
 direct scientific data in human are scarce and incomplete. On the
 other hand, alcohol is a toxic product whose irresponsible and
 excessive consumption has well-established consequences for health
 and serious social implications. Furthermore, some adverse effects
 have been related with the moderate consumption of alcoholic
 beverages, including an increase in the incidence of different
 types of cancer. In this article, a revision about the current
 knowledge about alcohol and health relationships is made, paying
 particular attention to the case of red wine. [Santos-Buelga,
