

## % of Significantly Gradient Metabolites per Sample Type, Morning *vs* Evening Studies

Figure S1: Percentage of observed metabolites/features undergoing a significant change between morning sample(s) and evening sample(s) as a function of rhythmic metabolites(features)/total metabolites(features).

Bars are indexed left to right

- A. [68]
- B. [67]
- C. [66]
- D. [76]
- E. [77]

Note: Total number of features observed in Sinues [76] study was not disclosed thus a % not calculated. The study and 'Breath' section is still presented to illustrate that such a study has taken place.

Data from [60,70,71] excluded as the total observed metabolites for these studies was not disclosed.

Figure S2: Percentage of observed significantly rhythmic metabolites and features as a function of rhythmic/total

Bars are indexed left to right

A. [46]	K. [45]
B. [37]	L. [57]
C. [61]	M. [54]
D. [63]	N. [72]
E. [54]	O. [73]
F. [56]	P. [81]
G. [58]	Q. [80]
H. [59]	R. [79]
I. [52]	S. [78]
J. [55]	

The quoted % of rhythmic metabolites reflects the number of rhythmic metabolites of the total observed across any and all conditions tested, specific individual test groups therefore observed less than the % shown here for the following studies: Davies, Isherwood, Skene, Gu, Kervezee, Honma, Luszczek, for a more detailed breakdown please see Table 2

Jerjes [69] was excluded due to primarily focussing on cortisol and its derivatives, markers of rhythmicity, and would skew the % of observed rhythmicity in urine.

Data from Gehrman [62] excluded as the total observed metabolites for these studies was not disclosed.
